BSM Search Techniques

(for the Large Hadron Collider)

Based on “A review of Mass Measurement Techniques proposed for the Large Hadron Collider”, Barr and Lester, [arXiv:1004.2732](https://arxiv.org/abs/1004.2732)

NExT-PhD Abingdon 2011

Christopher Lester
University of Cambridge

Recall \exists awkward problems ...

Aim was to fix some of these problems with the Standard Model

- Fine-tuning / “hierarchy problem” (technical) – **Why are particles light?**
- Does not explain **Dark Matter**
- No gauge coupling **unification**

[astro-ph/0608407](https://arxiv.org/abs/astro-ph/0608407)

What are common features of “solutions” to these problems?

- Big increase in particle content
- Longish decay chains
- Missing massive particles
- Large jet/lepton/photon multiplicity

At some point, 5000 people will shout:

**“We’ve found a ...
[long pause]
... SOMETHING!”**

*A large collider of hadrons ...
... not a collider of large hadrons*

How hard is it to identify
what was found?

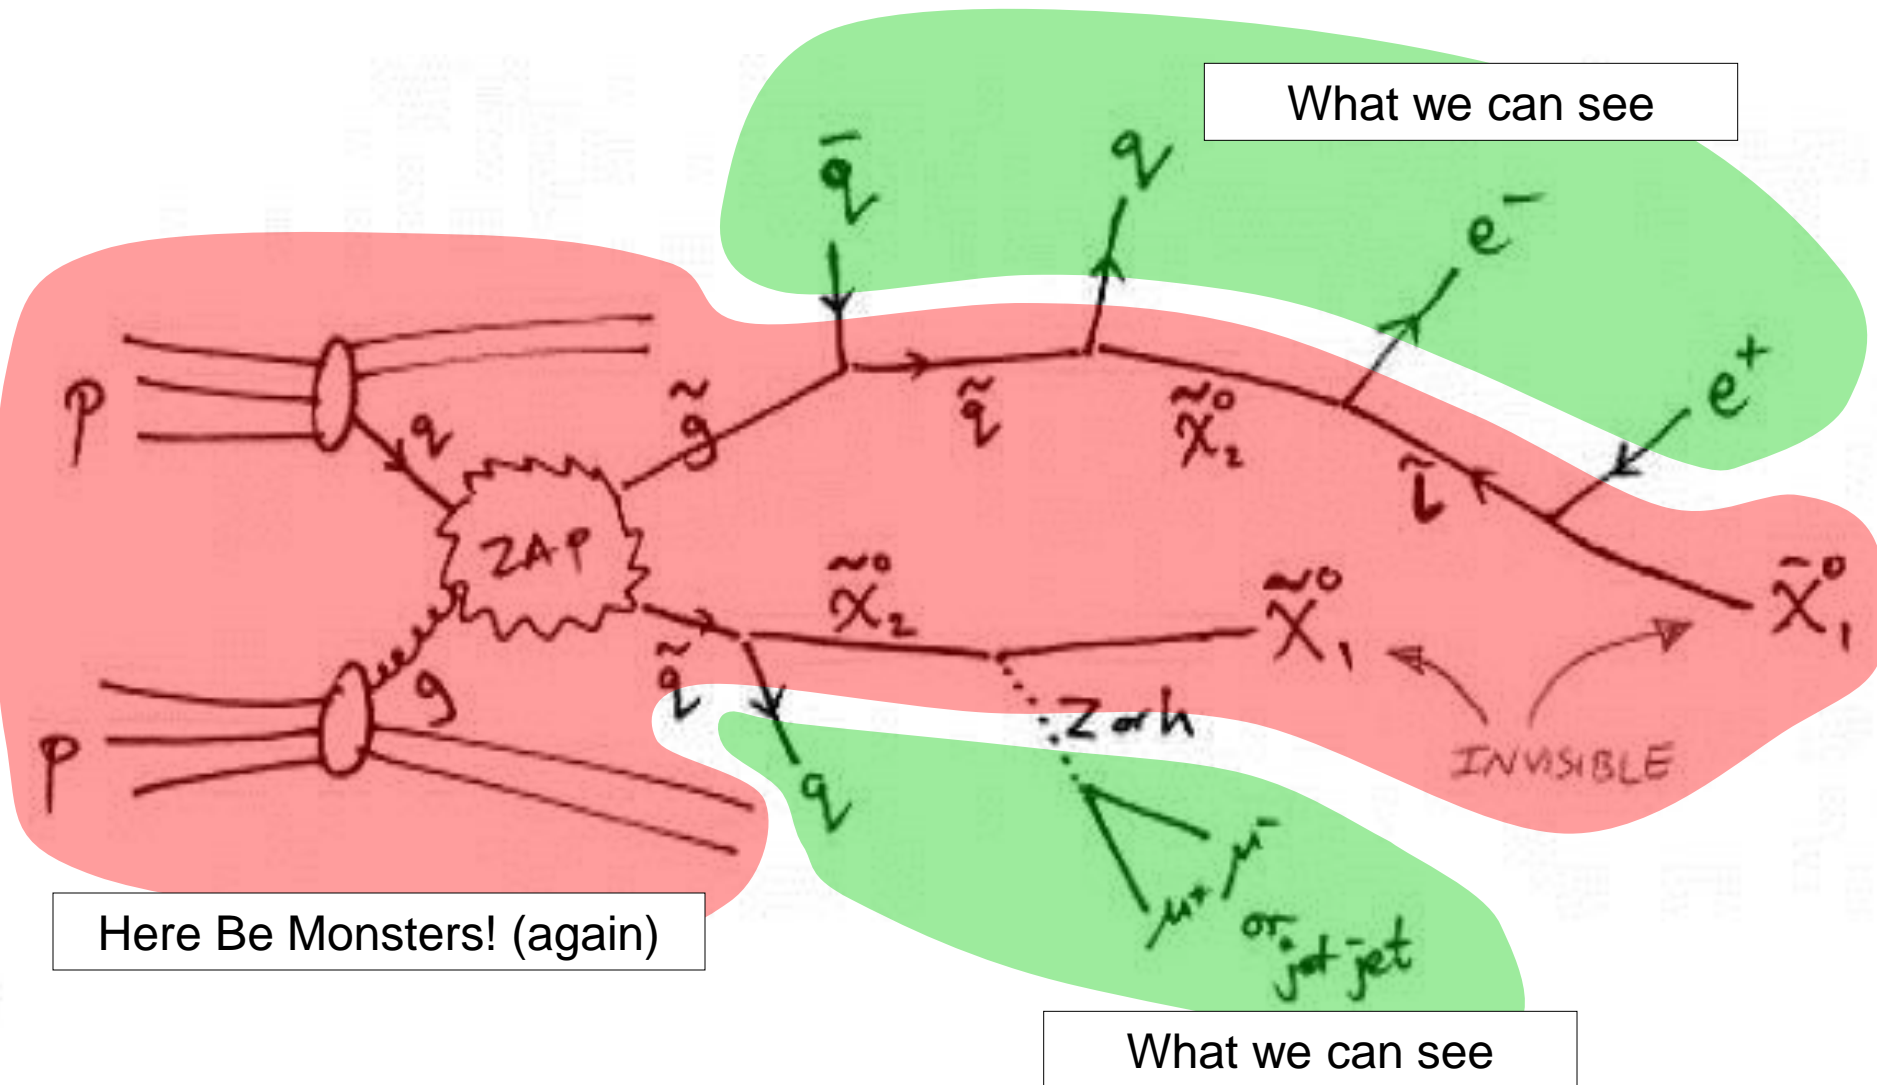

Want to emphasise what is visible at the LHC

- **Distinguish** the following from each other
 - Hadronic Jets,
 - B-jets (sometimes)
 - Electrons, Positrons, Muons, Anti-Muons
 - Tau leptons (sometimes)
 - Photons
- Measure **Directions** and **Momenta** of the above.
- Infer total **transverse momentum of invisible particles**. (eg neutrinos)

What do we NOT measure?

What might events look like?

This is the high energy physics of the 21st Century!

What events really look like scares me!

soft gluon radiation?

An example of an event where a higgs boson decayed to a pair of b-quarks/

Supersymmetry as Lingua Franca

Some possibilities:

- **Supersymmetry**
 - Minimal
 - Non-minimal
 - R-parity violating or conserving
- **Extra Dimensional Models**
 - Large (SM trapped on brane)
 - Universal (SM everywhere)
 - With/without small **black holes**
- “Littlest” Higgs ?
-

We will look
mainly at
supersymmetry
(SUSY)

Supersymmetry!

CAUTION!

- It may exist
- It may not
- First look for deviations from Standard Model!

Experiment must
lead theory.

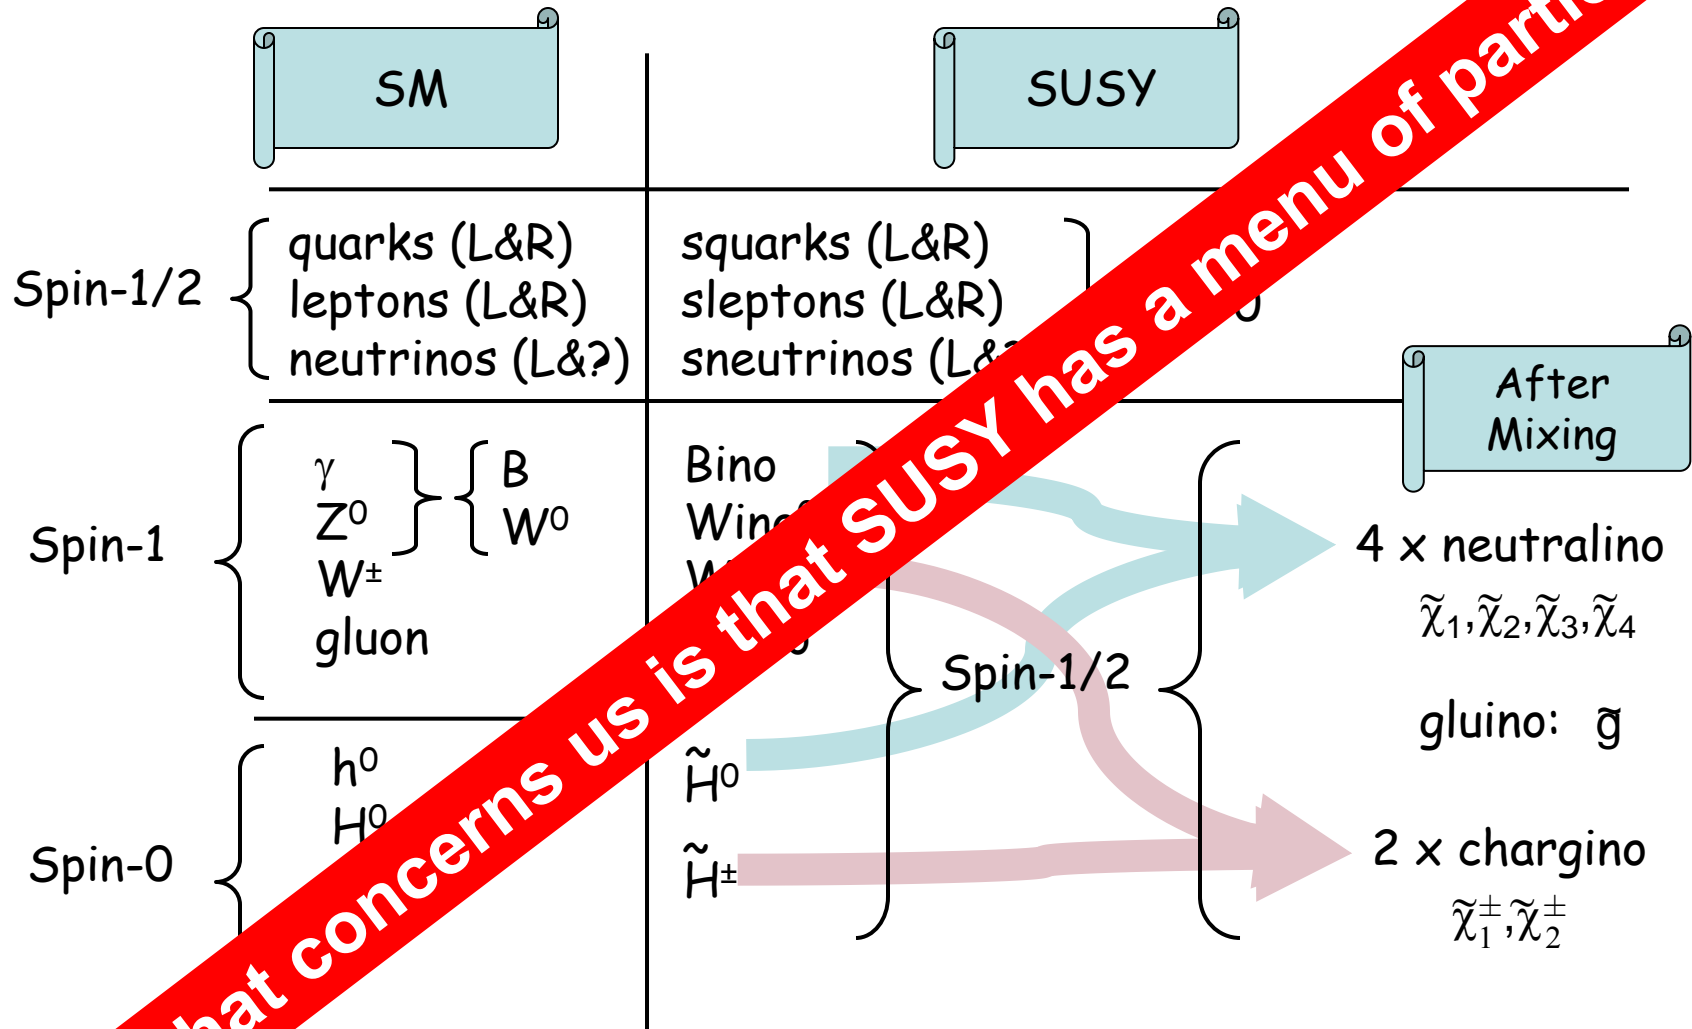

Gamble:

IF DEVIATIONS ARE SEEN:

- Old techniques won't work
- New physics not simple
- Can new techniques in SUSY but can apply them elsewhere.

SUSY particle content

All that concerns us is that SUSY has a menu of particles

Even in SUSY many possibilities

RPV

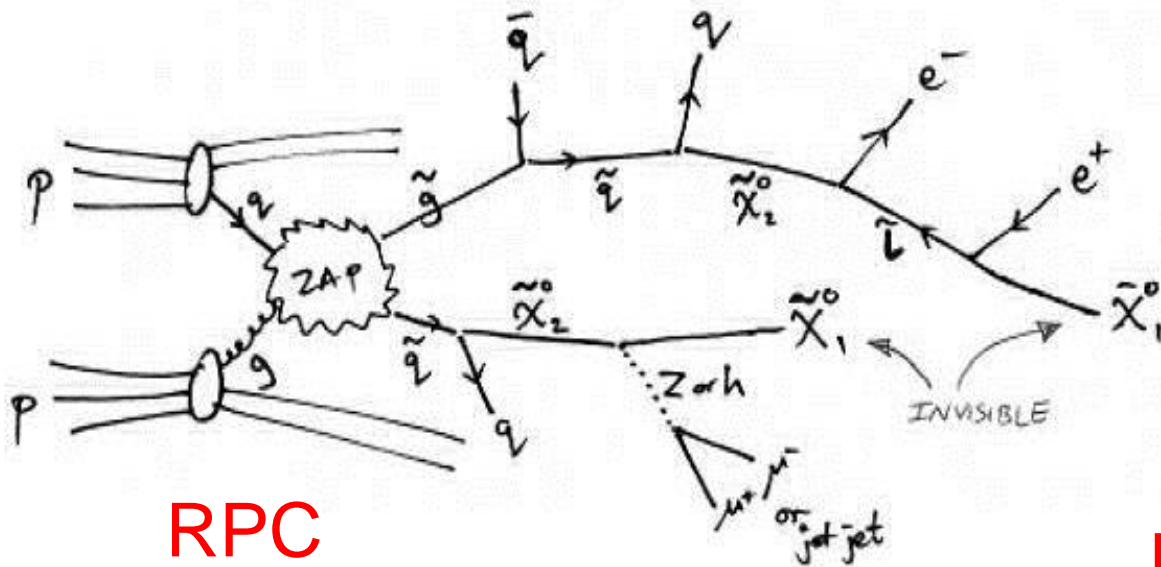

(Baryon number violating)

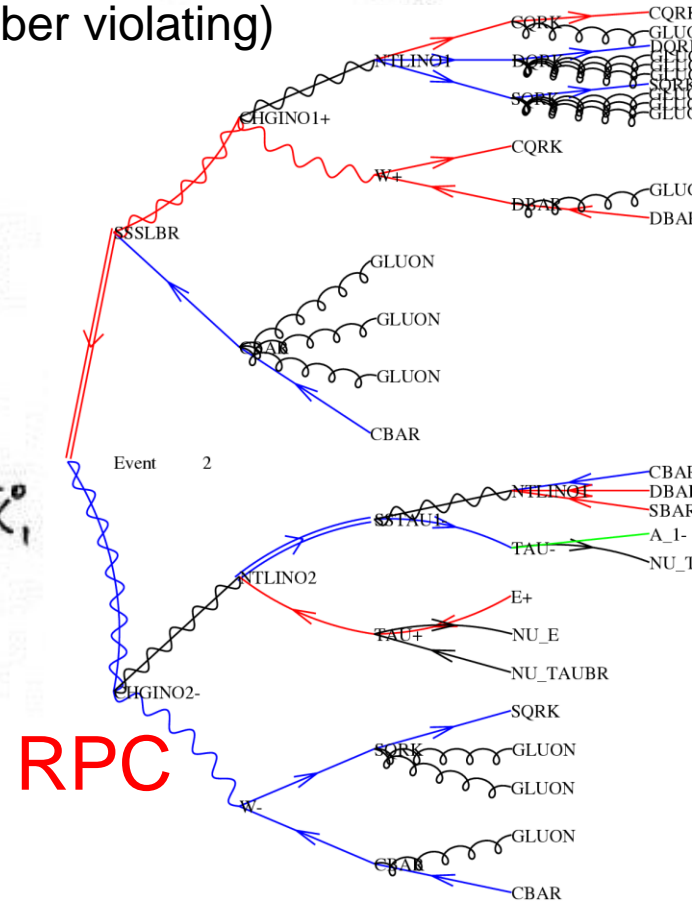

RPV

(Lepton number violating)

RPC

RPC

Do we care about masses?

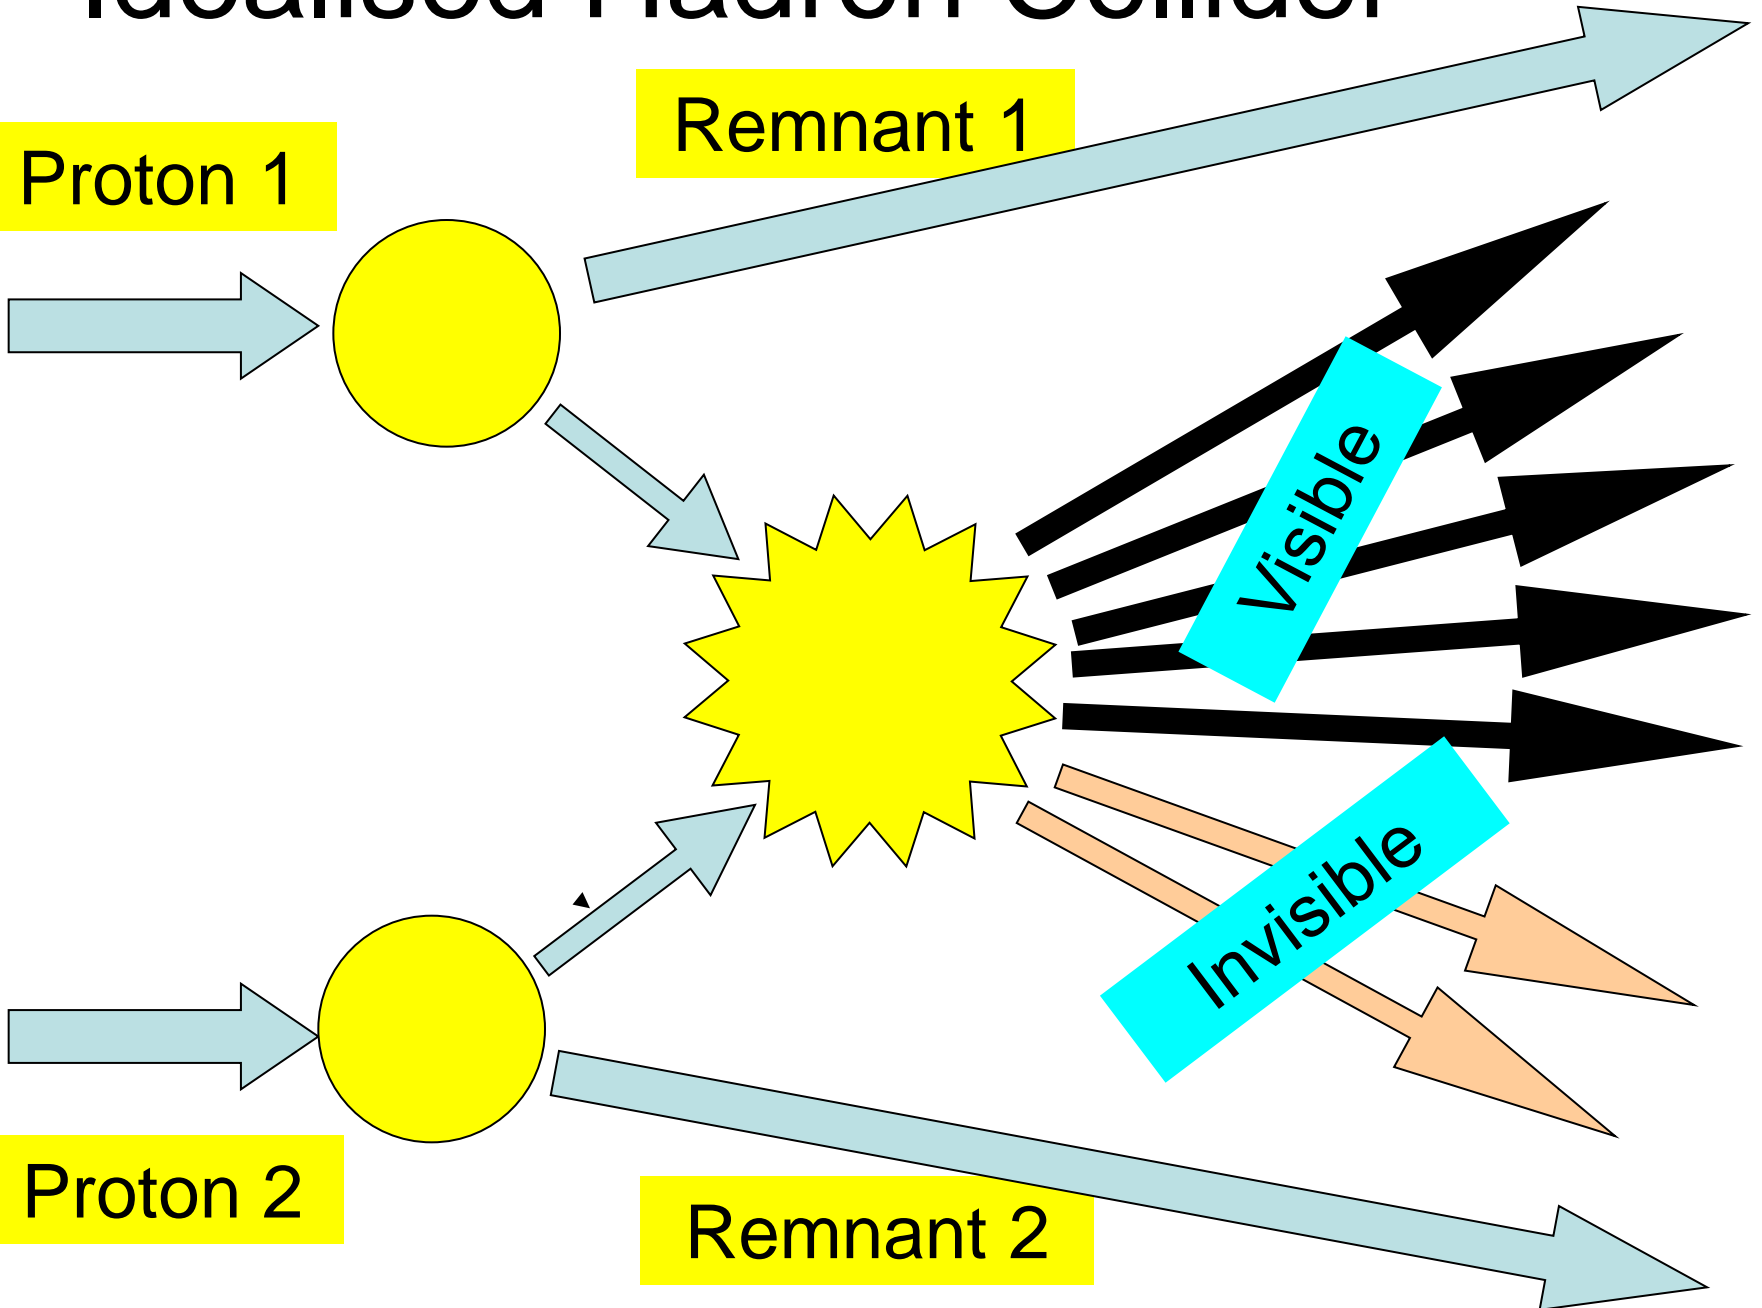

- Common **Parameter** in the Lagrangian
- Expedites **discovery** – optimal **selection**
- **Interpretation**
(SUSY breaking mechanism,
Geometry of Extra Dimensions)
- **Prediction** of new things
Mass of W,Z → indirect top quark mass “measurement”

A Review of the Mass Measurement Techniques proposed for the Large Hadron Collider

Alan J Barr*

*Department of Physics, Denys Wilkinson Building,
Keble Road, Oxford OX1 3RH, United Kingdom*

Christopher G Lester[†]

*Department of Physics, Cavendish Laboratory,
JJ Thomson Avenue, Cambridge, CB3 0HE, United Kingdom*

We review the methods which have been proposed for measuring masses of new particles at the Large Hadron Collider paying particular attention to the kinematical techniques suitable for extracting mass information when invisible particles are expected.

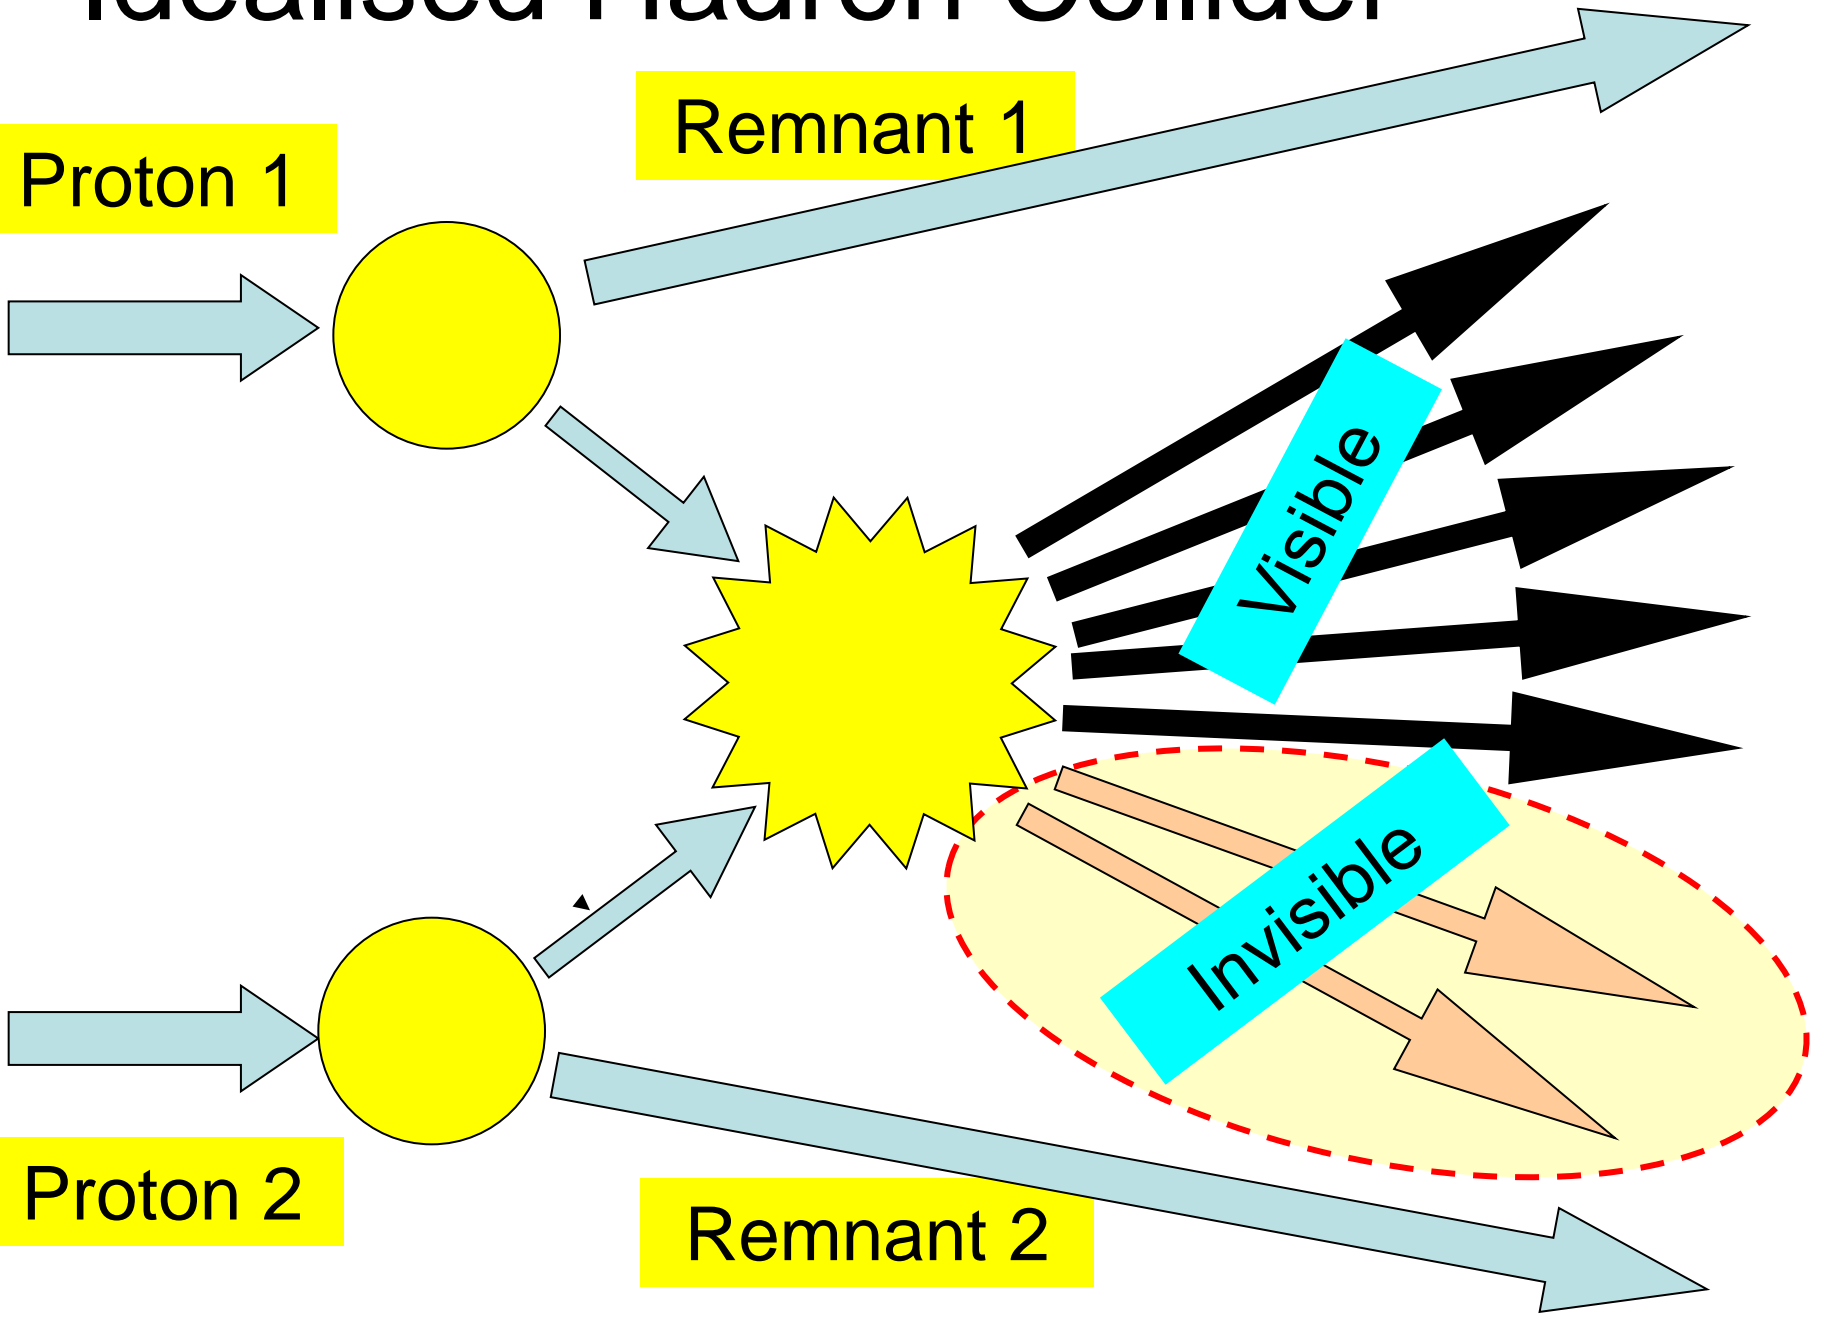

Scope and disclaimers

- will **not spend much time on fully visible final states** as standard mass reconstruction techniques apply
- will only consider **new particles of unknown mass** decaying to **invisible particles of unknown mass** (and other visible particles)
- selection bias – more emphasis on things I've worked with
 - Transverse masses, MT2, kinks, kinematic methods.
 - (Not Matrix Element / likelihood methods / loops)
- not shameless promotion – focus on **faults!**

Few assumptions,
Vague Conclusions.

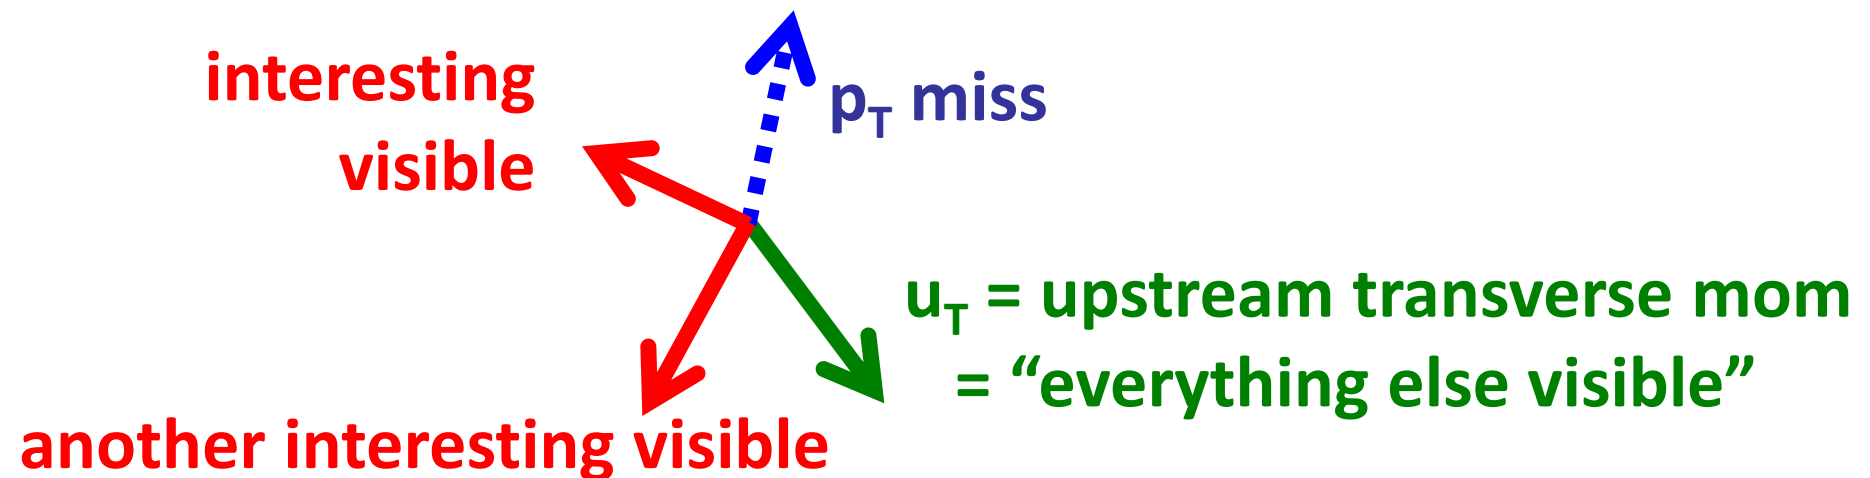

Anything with sensitivity
to mass scales.

Idealised Hadron Collider

Missing transverse momentum

$$\vec{\mathbf{p}}_T^{miss} = - \sum_i \vec{\mathbf{p}}_T^{i^{th} \text{ visible}}$$

Events have missing energy too, and it's not missing momentum

Rant about missing transverse momentum

- eT_{miss} – aaargh
- MET – AAAARGH
- missing energy – AAAAAARRRGH
- Blame LEP?
- Calorimeter apologists?
- alphaT

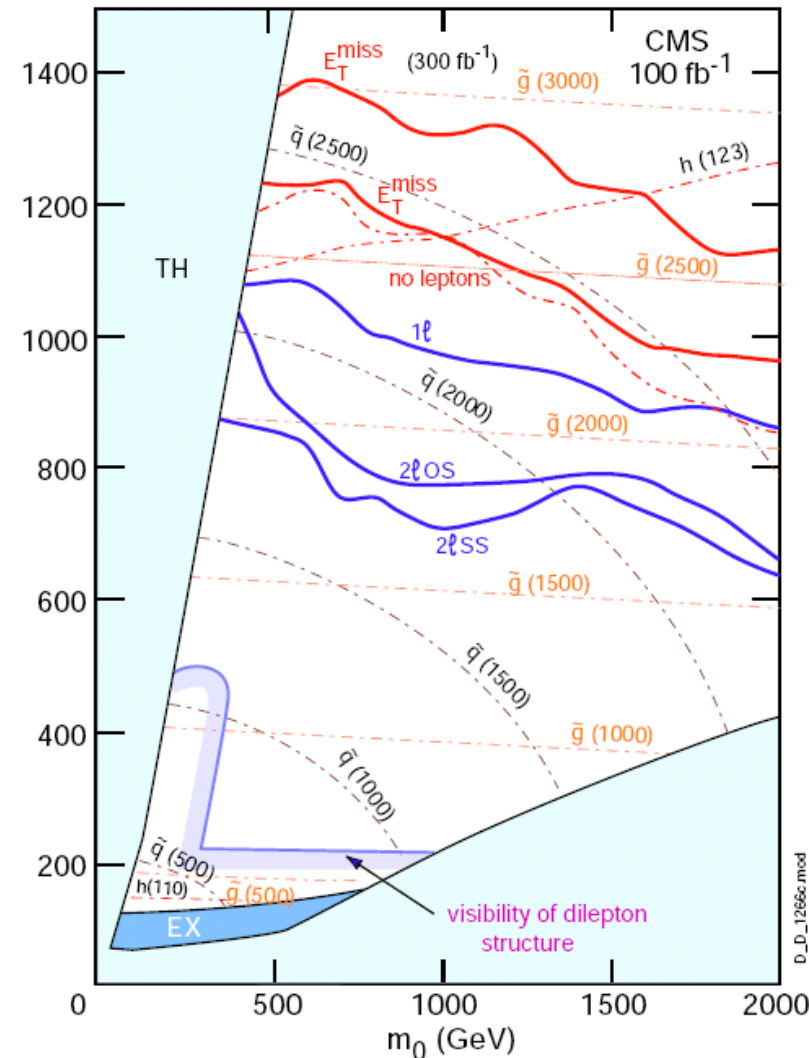

Main EASY signatures are:

- Lots of **missing pt**
- Lots of **leptons**
- Lots of **jets**

Just Count Events!

- $E_T^{\text{miss}} \Leftarrow$ Dominant signature
- E_T^{miss} with lepton veto
- One lepton
- Two leptons Same Sign (SS)
- Two leptons Opposite Sign (OS)

Simply count events containing the above

Perhaps

simple = best ?

-- The End --

Am in great danger of
appearing to sweep a
great number of LHC
analyses under here!

Not my intention at all!

Can attempt to spot susy by
counting “strange” events ...

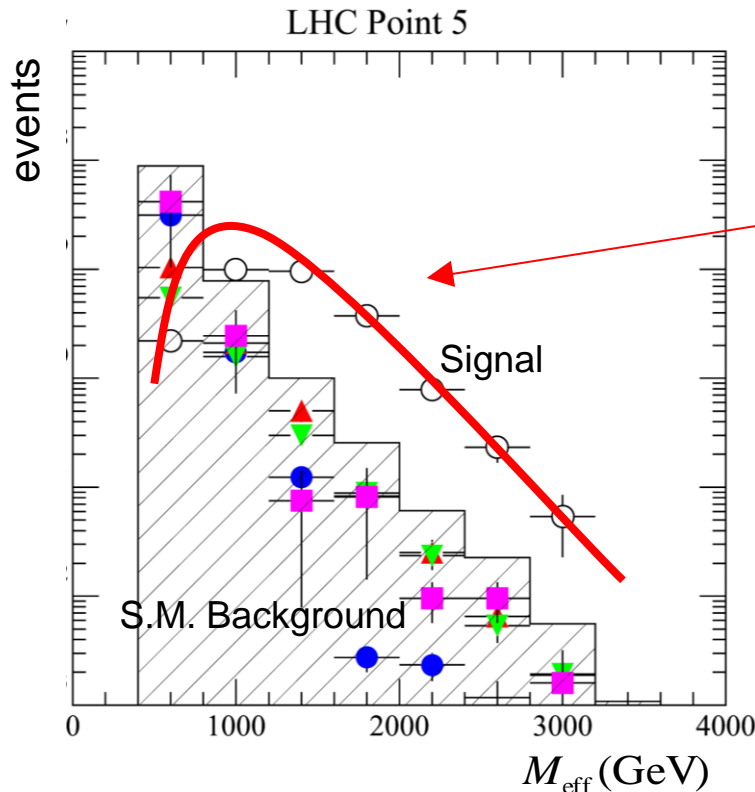

... but can we say anything
concrete about a mass scale?

Next example still low-tech

Effective mass

What you
histogram:

$$M_{\text{eff}} = \mathbf{p}_T^{\text{missing}} + \sum_i \left| \mathbf{p}_T^{\text{jet } i} \right|$$

You look for **position**
of this **peak** and call
it **MeffPeak**

Call it Meff and Mest too
(just to confuse people!)

What might M_{eff} peak position correlate with?

Define SUSY scale:

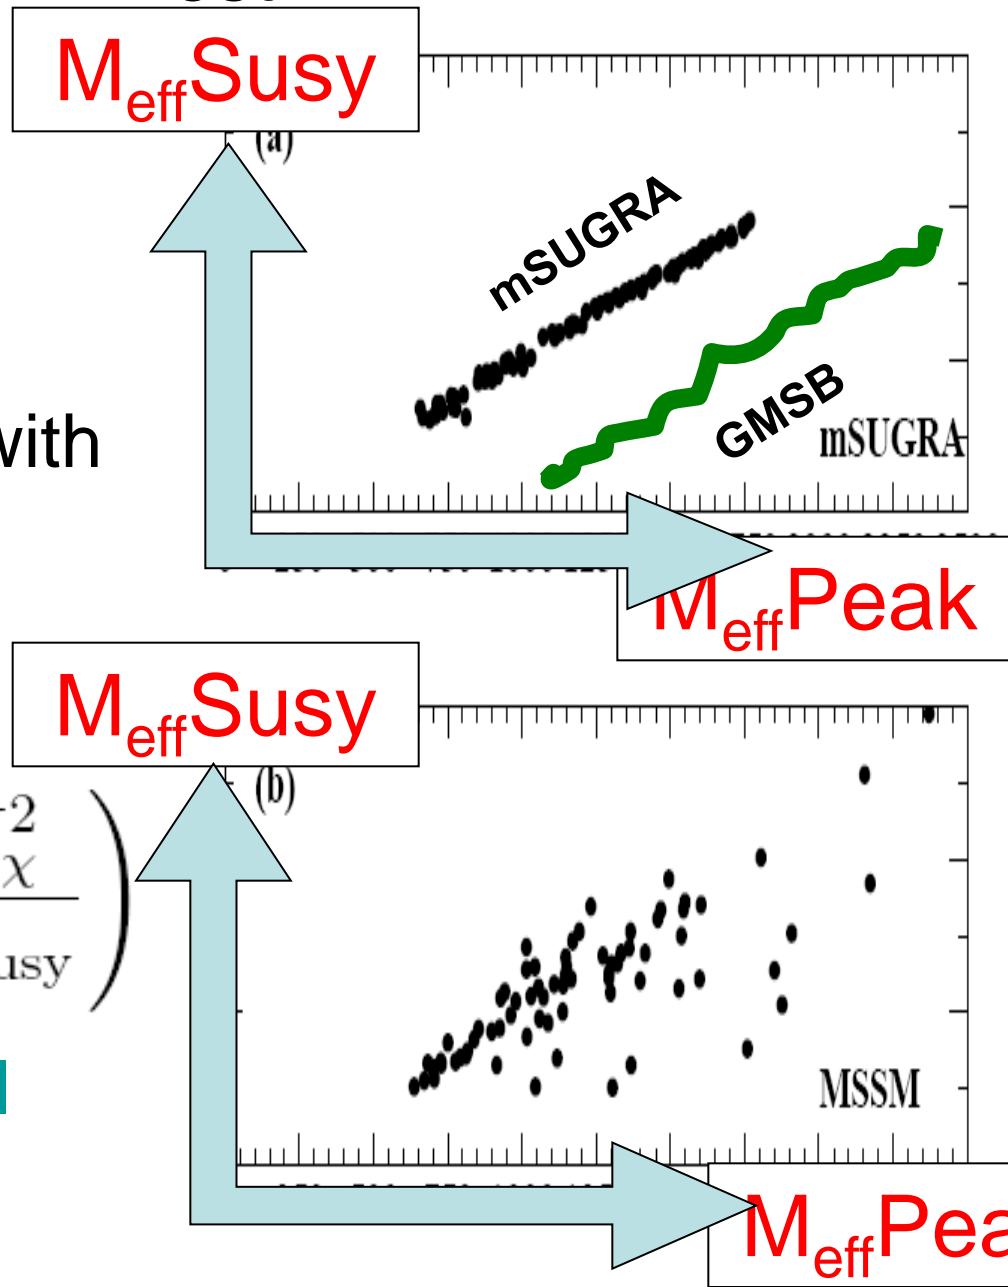

$$M_{\text{susy}}^{\text{eff}} = \left(M_{\text{susy}} - \frac{M_{\chi}^2}{M_{\text{susy}}} \right), \text{ with } M_{\text{SUSY}} \equiv \frac{\sum_i M_i \sigma_i}{\sum_i \sigma_i}$$

$M_{\text{effPeak}} / M_{\text{est}}$ example

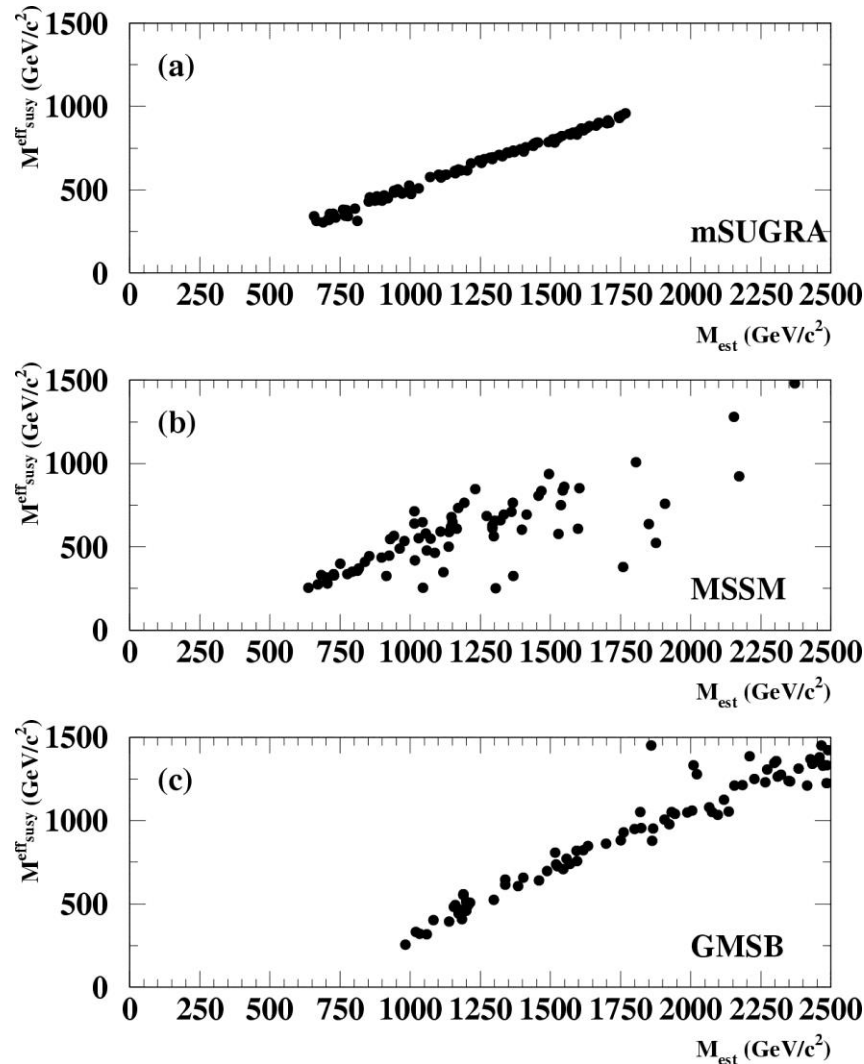

Observable M_{effPeak}
sometimes correlates with
property of model M_{eff}
defined by

$$M_{\text{susy}}^{\text{eff}} = \left(M_{\text{susy}} - \frac{M_{\chi}^2}{M_{\text{susy}}} \right)$$

but correlation is model
dependent

Correlations between MeffPeak position and MeffSusy

(Tovey)

M_Hotpants ..

- Can encourage tendency to

- Create your variable, then see what might be able to measure. Oops.

Effective mass

What you
histogram:

$$M_{\text{eff}} = p_T^{\text{missing}} + \sum_l |p_T^l|$$

You look for position
of this peak and call

**“It is neither a mass,
nor effective” - KM**

Call it M_{eff} too (just
to confuse people!)

Meff is not alone ...

Murky underworld of hidden relatives known variously as HT ... same thing ... sometimes

$$H_T = E_{T(2)} + E_{T(3)} + E_{T(4)} + |\not{\mathbf{p}}_T|$$

$$E_T = E \sin \theta$$

See arXiv:1105.2977 for why sinTheta brings on nightmares.

(There are **no standard definitions** of H_T or Meff. Authors differ in how many jets are used, whether PT miss should be added etc.)

All have *some* sensitivity to the overall mass scales involved, but *interpretation requires a model and more assumptions.*

Why are we adding transverse momenta?

- Why not multiply?
(or add logs)?
- Serious proposal to use $M_{\text{eff}}^2 - (u_T)^2$ in [arXiv:1105.2977](#)
- Why are the signs the same? Why equal weights? Silly?
- **How many years** would it take ATLAS/CMS to discover the **invariant mass for $Z \rightarrow a b$** ?

$$M_{happy} = \left(\prod_{i=1}^n \mathbf{p}_T^i \right)^{\frac{1}{n}}$$

$$M^2 = \left(\sqrt{m_a^2 + a_x^2 + a_y^2 + a_z^2} + \sqrt{m_b^2 + b_x^2 + b_y^2 + b_z^2} \right)^2 - (a_x + b_x)^2 - (a_y + b_y)^2 - (a_z + b_z)^2$$

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

Highest Meff event so far

The highest Meff in any (supposedly “clean”) ATLAS event is 1548 GeV

- calculated from four jets with pts:
 - 636 GeV
 - 189 GeV
 - 96 GeV
 - 81 GeV
- 547 GeV of missing transverse momentum.

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

MSUGRA/CMSSM: $\tan\beta = 10$, $A_0 = 0$, $\mu > 0$

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

Don't confuse simplicity with
complexity ... can layer add many
layers of interpretation

Measure top quark mass from mean lepton P_T only!

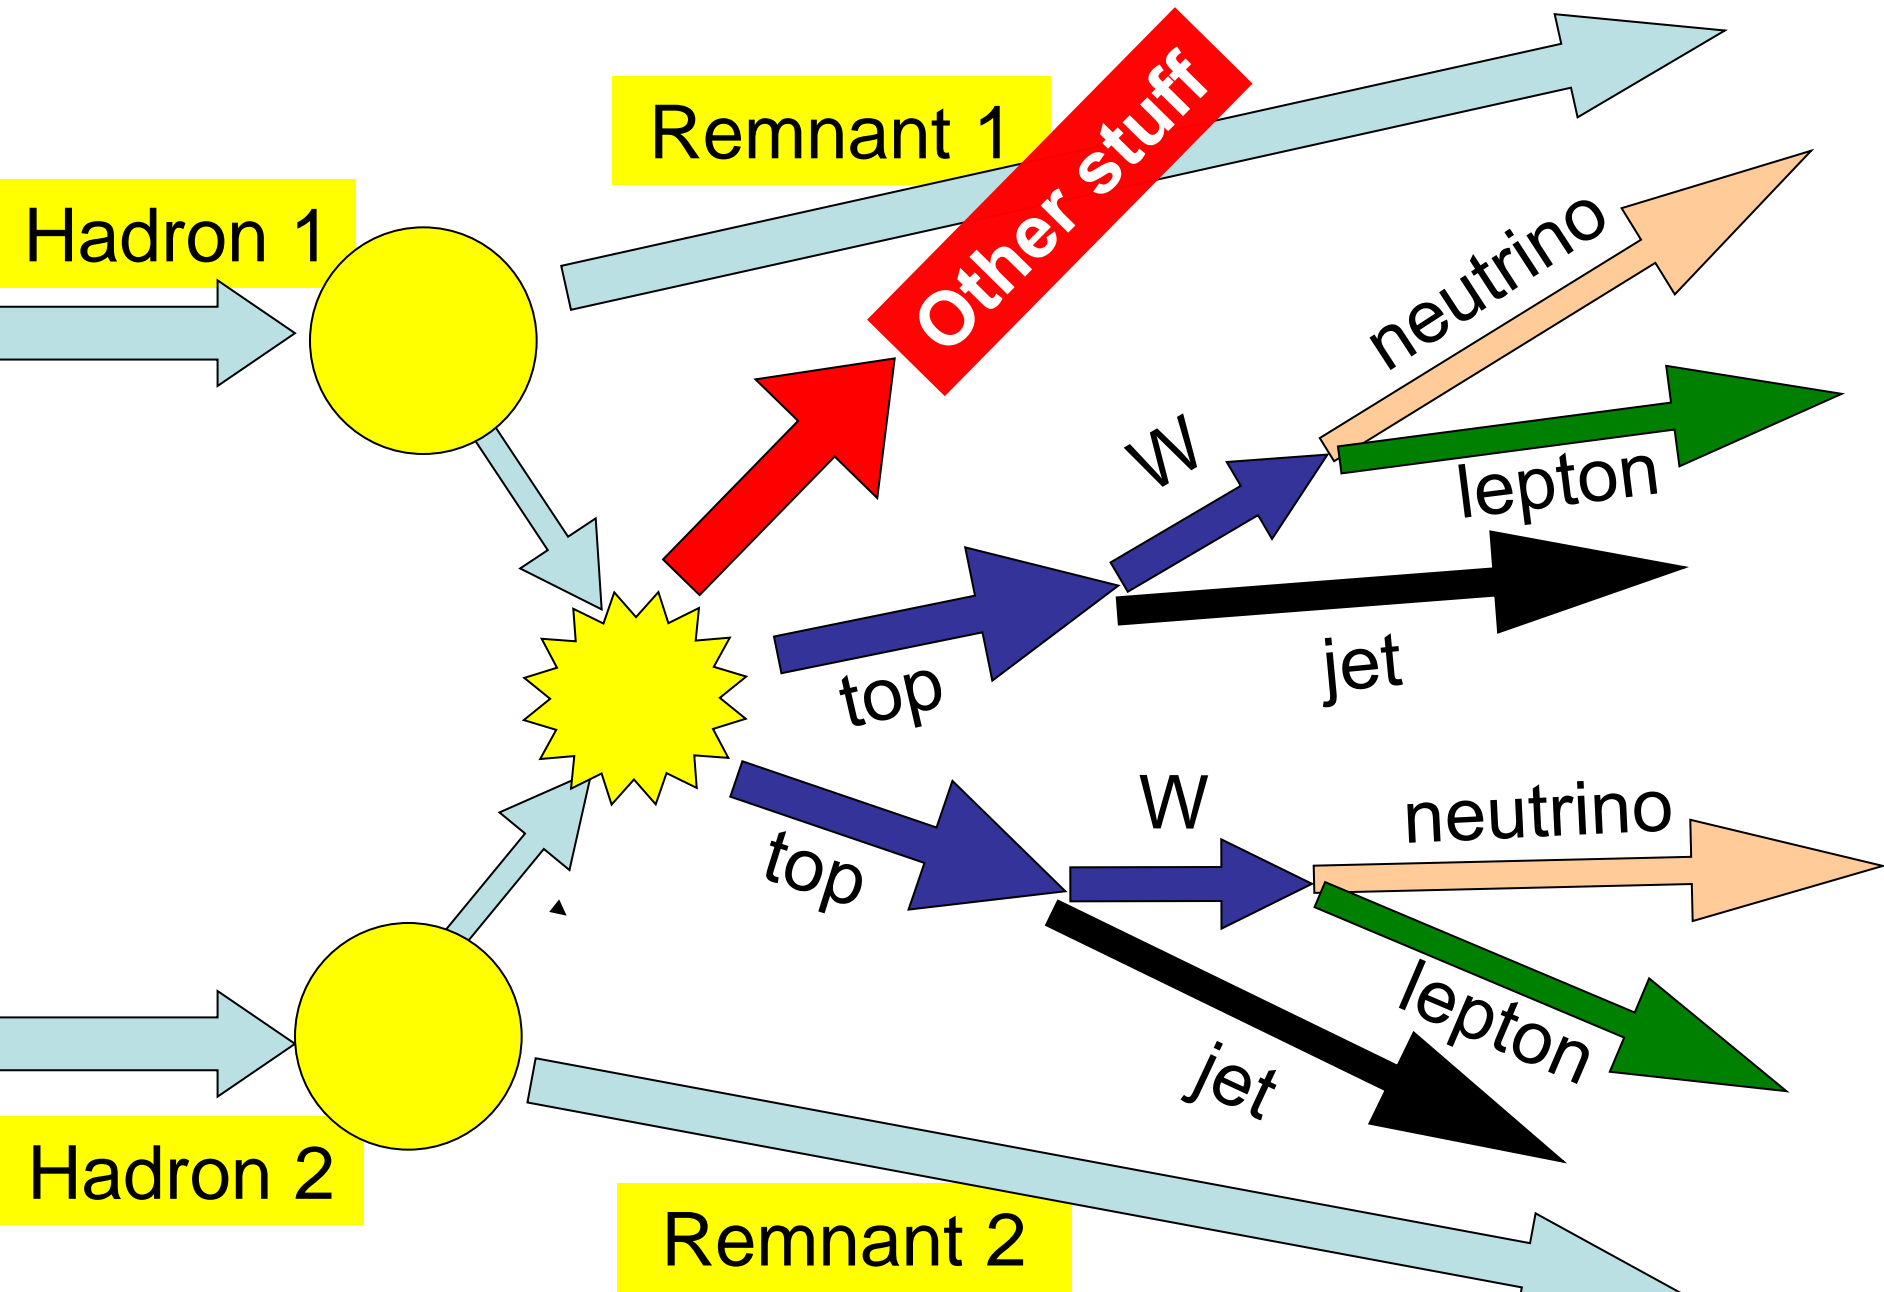

CDF note 8959

Measurement of the top quark mass from the lepton transverse momentum in the
 $t\bar{t} \rightarrow$ dilepton channel at the Tevatron

A new measurement of the top quark mass at 1.8 fb^{-1} integrated luminosity, using leptons' P_T in the dilepton channel is presented. A top quark mass of $m_{\text{top}} = 156 \pm 20_{(\text{stat})} \pm 4.6_{(\text{syst})} \text{ GeV}/c^2$ is obtained with the Likelihood method and of $149 \pm 21_{(\text{stat})} \pm 5_{(\text{syst})} \text{ GeV}/c^2$ is obtained with the Straight Line method.

Top quark production tevatron - dileptonic

Frightening y-axis!

Mean lepton pT

Simulated top quark mass

Result

$$m_{\text{top}} = 156 \pm 20_{(\text{stat})} \pm 4.6_{(\text{syst})} \text{ GeV}$$

Moral

- You can monte-carlo anything.
 - example $h \rightarrow \tau \tau$
- But do you trust it? Is it the best you can do?

More assumptions
Less Vague Conclusions

non-hotpants

Topology / hypothesis

Must impose some interpretation

Design the variable to suit the interpretation

EXPERIMENT

ELECTRON

Missing momentum

Historical solution: (full!) W transverse mass

$$m_T^2 = m_e^2 + m_\nu^2 + 2(e_e e_\nu - \mathbf{p}_T^e \cdot \mathbf{p}_T^\nu)$$

$$e_e = \sqrt{m_e^2 + p_{Te}^2}$$

$$e_\nu = \sqrt{m_\nu^2 + p_{T\nu}^2}$$

!! NOT THIS !!

$$m_T = \sqrt{2|\vec{P}_{Te}||\vec{P}_{T\nu}|(1 - \cos \mathcal{G})}$$

!! This is **NOT** the transverse mass !!

W transverse mass: nice properties

- In every event $m_T < m_W$ if the W is on shell
- There are events in which m_T can **saturate** the bound on m_W .

motivate m_T in W discovery and mass measurements.

But where did these properties come from?

Re-examine invariant mass: $M \rightarrow a b$

$$\begin{aligned} M^2 &= \left(\sqrt{m_a^2 + a_x^2 + a_y^2 + a_z^2} + \sqrt{m_b^2 + b_x^2 + b_y^2 + b_z^2} \right)^2 \\ &\quad - (a_x + b_x)^2 - (a_y + b_y)^2 - (a_z + b_z)^2 \\ &= (E_a + E_b)^2 - (a_x + b_x)^2 - (a_y + b_y)^2 - (a_z + b_z)^2 \\ &= m_a^2 + m_b^2 + 2(E_a E_b - a_x b_x - a_y b_y - a_z b_z) \end{aligned}$$

$$= m_a^2 + m_b^2 + 2(e_a e_b \cosh(\Delta\eta) - a_x b_x - a_y b_y)$$

where

$$\begin{aligned} e_a &= \sqrt{m_a^2 + a_x^2 + a_y^2} & \text{and} & & \eta_a &= \frac{1}{2} \ln((E_a + a_z)/(E_a - a_z)) \\ e_b &= \sqrt{m_b^2 + a_b^2 + a_b^2} & & & \eta_b &= \frac{1}{2} \ln((E_b + b_z)/(E_b - b_z)) \\ & & & & \Delta\eta &= \eta_a - \eta_b \end{aligned}$$

Comparing invariant and transverse masses:

$$M^2 = m_a^2 + m_b^2 + 2(e_a e_b \cosh(\Delta\eta) - a_x b_x - a_y b_y)$$
$$M_T^2 = m_a^2 + m_b^2 + 2(e_a e_b - a_x b_x - a_y b_y)$$

Since $\cosh(\Delta\eta) \geq 1$ have $M_T \leq M$

with equality when $\Delta\eta = 0$.

(Not same as throwing away z information!)

But have bound, and bound can be saturated.

Note that at this point we are assuming we know m_b .

W boson mass measurement

In the data....

Alternative way of approaching the problem

Set out **INTENDING** to
construct best lower

bound

on $(P_e + P_v)^2$

given the constraints

Constraints in this instance:

$$0 = (P_v)^2 \quad [massless\ neutrino]$$

$$0 = \Sigma \mathbf{p}_T = \mathbf{u}_T + \mathbf{p}_T(e) + \mathbf{p}_T(v)$$

[momentum conservation in transverse plane]

Suggests general prescription...

- (1) Propose a decay **topology**
- (2) Write down your the **Lorentz Invariant** of choice
- (3) Write down the **constraints**
- (4) **Calculate** the bound (algebraically/numerically/mix)

$$(2) \quad \mathcal{M}_a \equiv \sqrt{g_{\mu\nu} (\mathbf{P}_a + \mathbf{Q}_a)^\mu (\mathbf{P}_a + \mathbf{Q}_a)^\nu}$$

$$(3) \quad \sum_{i=1}^{N_{\mathcal{I}}} \vec{q}_{iT} = \vec{p}_T \equiv -\vec{u}_T - \sum_{i=1}^{N_{\mathcal{V}}} \vec{p}_{iT}$$

Single parent ... multiple daughters

many visibles

many invisibles

$$M_{\text{IT}}^2 = \left(\sqrt{M_P^2 + \vec{\mathbf{p}}_T^2} + \sqrt{M_{\text{slash}}^2 + \vec{\mathbf{q}}_{T\text{miss}}^2} \right)^2 - u_T^2$$

$$M_{\text{slash}} = \sum_i \tilde{M}_i$$

Bound depends on *GUESS* masses of ***all*** invisible daughters

Most conservative: **set to zero**

[more later]

Almost exactly same as transverse mass –
one small generalization

$$M_{1T}^2 = \left(\sqrt{M_P^2 + \vec{\mathbf{p}}_T^2} + \sqrt{M_{\text{slash}}^2 + \vec{\mathbf{q}}_{T\text{miss}}^2} \right)^2 - u_T^2$$
$$M_T^2 = \left(\sqrt{M_P^2 + \vec{\mathbf{p}}_T^2} + \sqrt{M_Q^2 + \vec{\mathbf{q}}_{T\text{miss}}^2} \right)^2 - u_T^2$$

The “invisible mass” has become a parameter rather than the actual visible mass.

We will come back to this many times.

Suggests we should think about non-physical parameters a bit more

Applications of M_{1T} ?

Higgs \rightarrow $WW^* \rightarrow$ $lvlv$

$$Q_1^\mu Q_{1\mu} = 0,$$

$$Q_2^\mu Q_{2\mu} = 0,$$

$$\vec{q}_{1T} + \vec{q}_{2T} = \vec{p}_T.$$

Higgs $\rightarrow WW^* \rightarrow \ell\nu\ell\nu$

Previous variable
(not a bound)

Why are
endpoints often
more robust than
shapes?

Proper bound
var MTTrue = M1T

FIG. 1: Signal-only distributions of m_T^{approx} (top) and m_T^{true} (bottom) for various values of m_h (in GeV). No cuts on $\Delta\phi_{\ell\ell}^{\text{max}}$ and p_{TW}^{min} have been applied.

Against the 2010 LHC data...

Big improvement in LHC Higgs Search

ATLAS 35/pb: $H \rightarrow WW \rightarrow \ell\nu\ell\nu$

change of topic –
moving closer to BSM

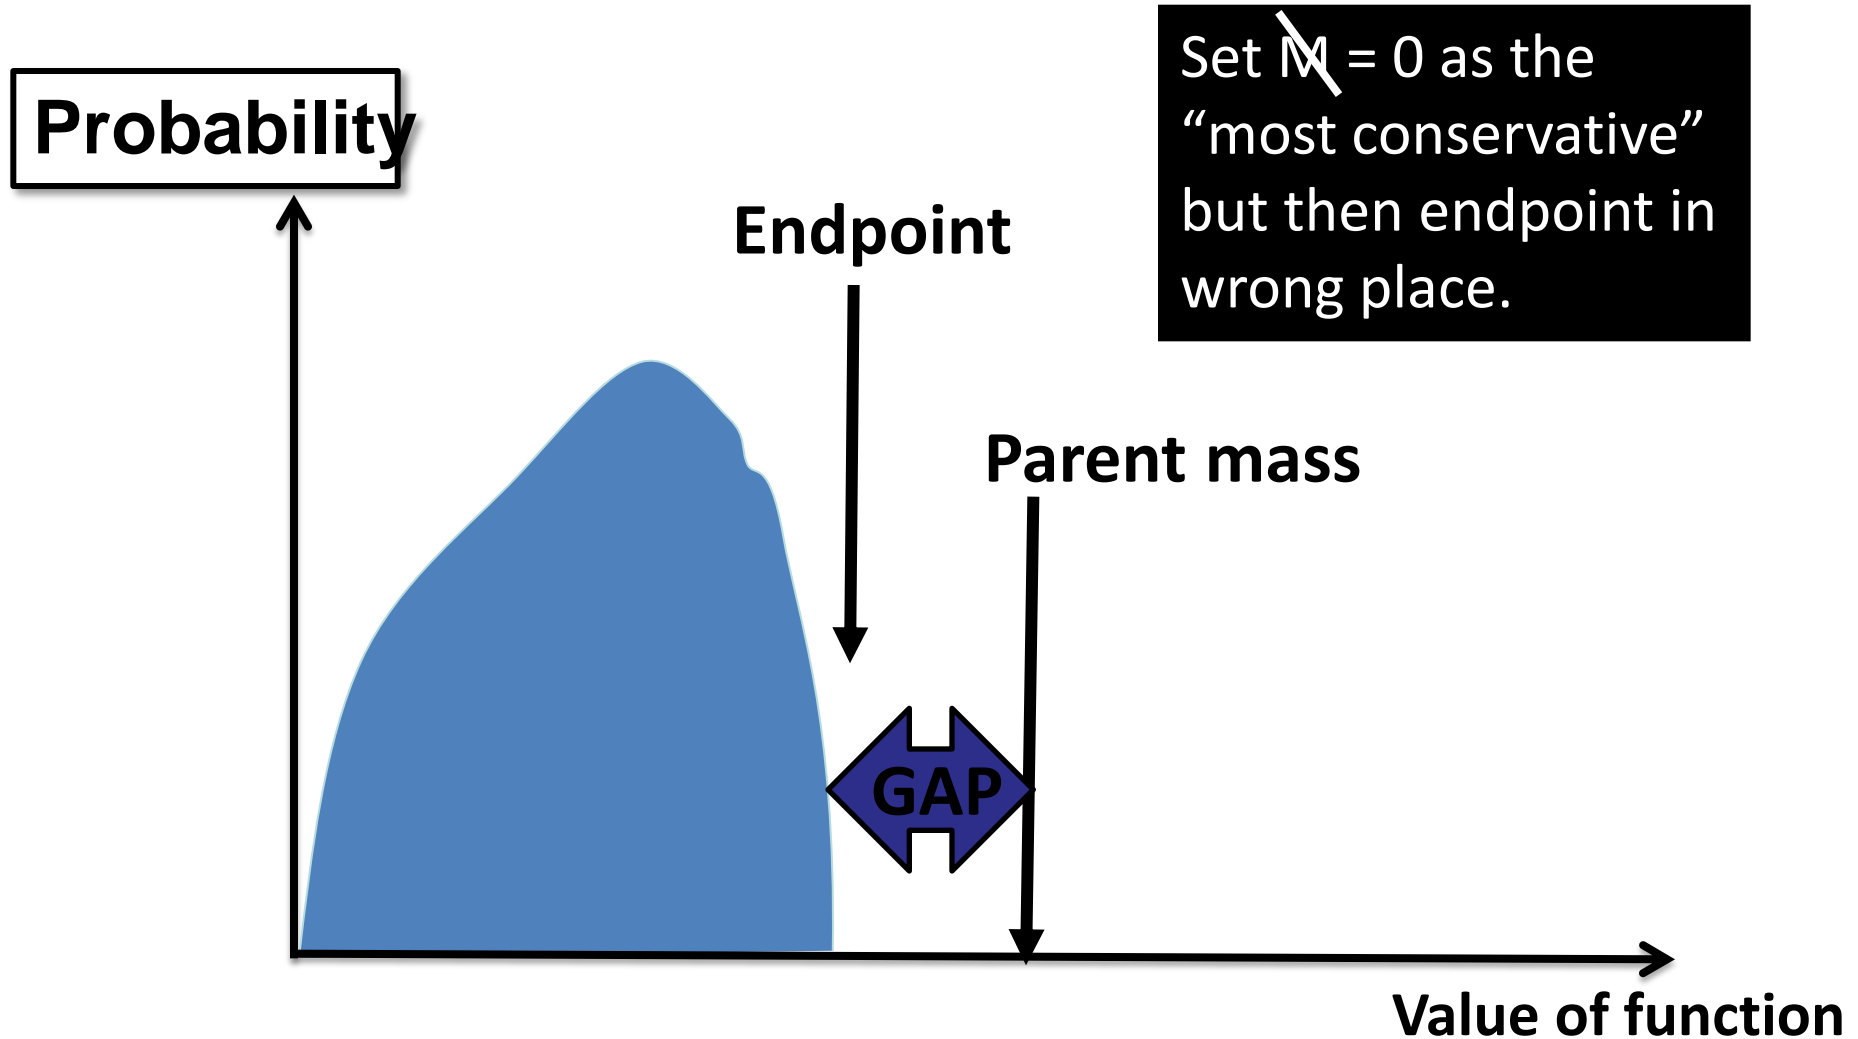

What if we don't know the masses of the invisible particle(s)?

Can we construct a maximal lower bound on M_A that depends on a **hypothesis for M_B** ?

Hmm

“wrong M_B ” not what M_T was designed for.

Let's go back to the (full)
transverse mass again for
a closer look!

In next few slides:

χ = Guess (i.e. hypothesis) for mass of the invisible daughter

In other words, we will use χ in all the places we previously used M_B .

Schematically, all we have guaranteed so far is the picture below:

- Since “ χ ” can now be “wrong”, some of the properties of the transverse mass can “break”:
- $m_T(\chi)$ max is no longer invariant under transverse boosts! (except when $\chi = m_B$)
- $m_T(\chi) < m_A$ may no longer hold! (however we always retain: $m_T(m_B) < m_A$)

Actual dependence on invisible
mass guess χ more like this:

In fact, we get this **very nice result**:

The “full” transverse mass curve is the boundary of the region of (mother,daughter) masses consistent with the observed event!

Minimal Kinematic Constraints and $m(T_2)$,
Hsin-Chia Cheng and Zhenyu Han (UCD)
e-Print: [arXiv:0810.5178 \[hep-ph\]](https://arxiv.org/abs/0810.5178) and
“**Transverse masses and kinematic constraints, from the Boundary to the Crease**” [arXiv:0908.3779](https://arxiv.org/abs/0908.3779)

Event 1 of 8

Event 2 of 8

Event 3 of 8

Event 4 of 8

Event 5 of 8

Event 6 of 8

Event 7 of 8

Event 8 of 8

Overlay all 8 events

Overlay many events

Here is a transverse mass “KINK”

Alternatively, look at M_T distributions for a variety of values of **chi**.

Each curve has a different value of **chi**

m_T

Where is the kink now?

What causes the kink?

- Two entirely independent things can cause the kink:
 - (1) Variability in the “visible mass”
 - (2) Recoil of the “interesting things” against Upstream Transverse Momentum
- Which is the dominant cause depends on the particular situation ... let us look at each separately:

Kink cause 1: Variability in visible mass

- m_{Vis} can change from event to event
- Gradient of $m_T(\chi)$ curve depends on m_{Vis}
- Curves with **low** m_{Vis} tend to be “**flatter**”

Kink cause 1: Variability in visible mass

- m_{Vis} can change from event to event
- Gradient of $m_T(\chi)$ curve depends on m_{Vis}
- Curves with **high** m_{Vis} tend to be “**steeper**”

Kink cause 2 :
Recoil against Upstream Momentum

Kink cause 2: Recoil against UTM

- UTM can change from event to event
- Gradient of $m_T(\chi)$ curve depends on UTM
- Curves with UTM **parallel** to visible momenta tend to be “**flatter**”

Kink cause 2: Recoil against UTM

- UTM can change from event to event
- Gradient of $m_T(\chi)$ curve depends on UTM
- Curves with UTM **opposite** to visible momenta tend to be “**steeper**”

Health warning!

(for those of you interested in
LHC dark matter constraints)

Rather worryingly, M_T kinks are at present the only known **kinematic** methods which (at least in principle) allow determination of the mass of the invisible particle in short chains at hadron colliders!

[We will see a **dynamical** method that works for single three+ body decays shortly. **Likelihood** methods can determine masses in pair decays too, though at cost of model dependence and CPU. See Alwall.]

That last statement should worry you!

$m_T(\chi)$

CASE 3v

Spot the kink

Varying “ χ ” ... to first order see:

Take home messages for MT

- **EASY to get MASS DIFFERENCE**
- We have two **independent kinematical** opportunities to measure **invisible daughter mass** in single particle decays:
 - “Upstream boost induced” MT kink
 - from ISR alone, useless, from real UTM, possible
 - “Variable visible mass induced” MT kink
 - impossible in 2-body decay, otherwise possible
 - **HARD to set absolute mass scale**
- We used pT-miss information – so only works with one invisible (so far ...)

Change of topic:

How do we measure
masses when there is
Pair Production ?

A popular new-physics scenario

Example:

We have two copies of this:

But don't know p_T of B this time! 😞

a possible "splitting"

another possible “splitting”

another possible "splitting"

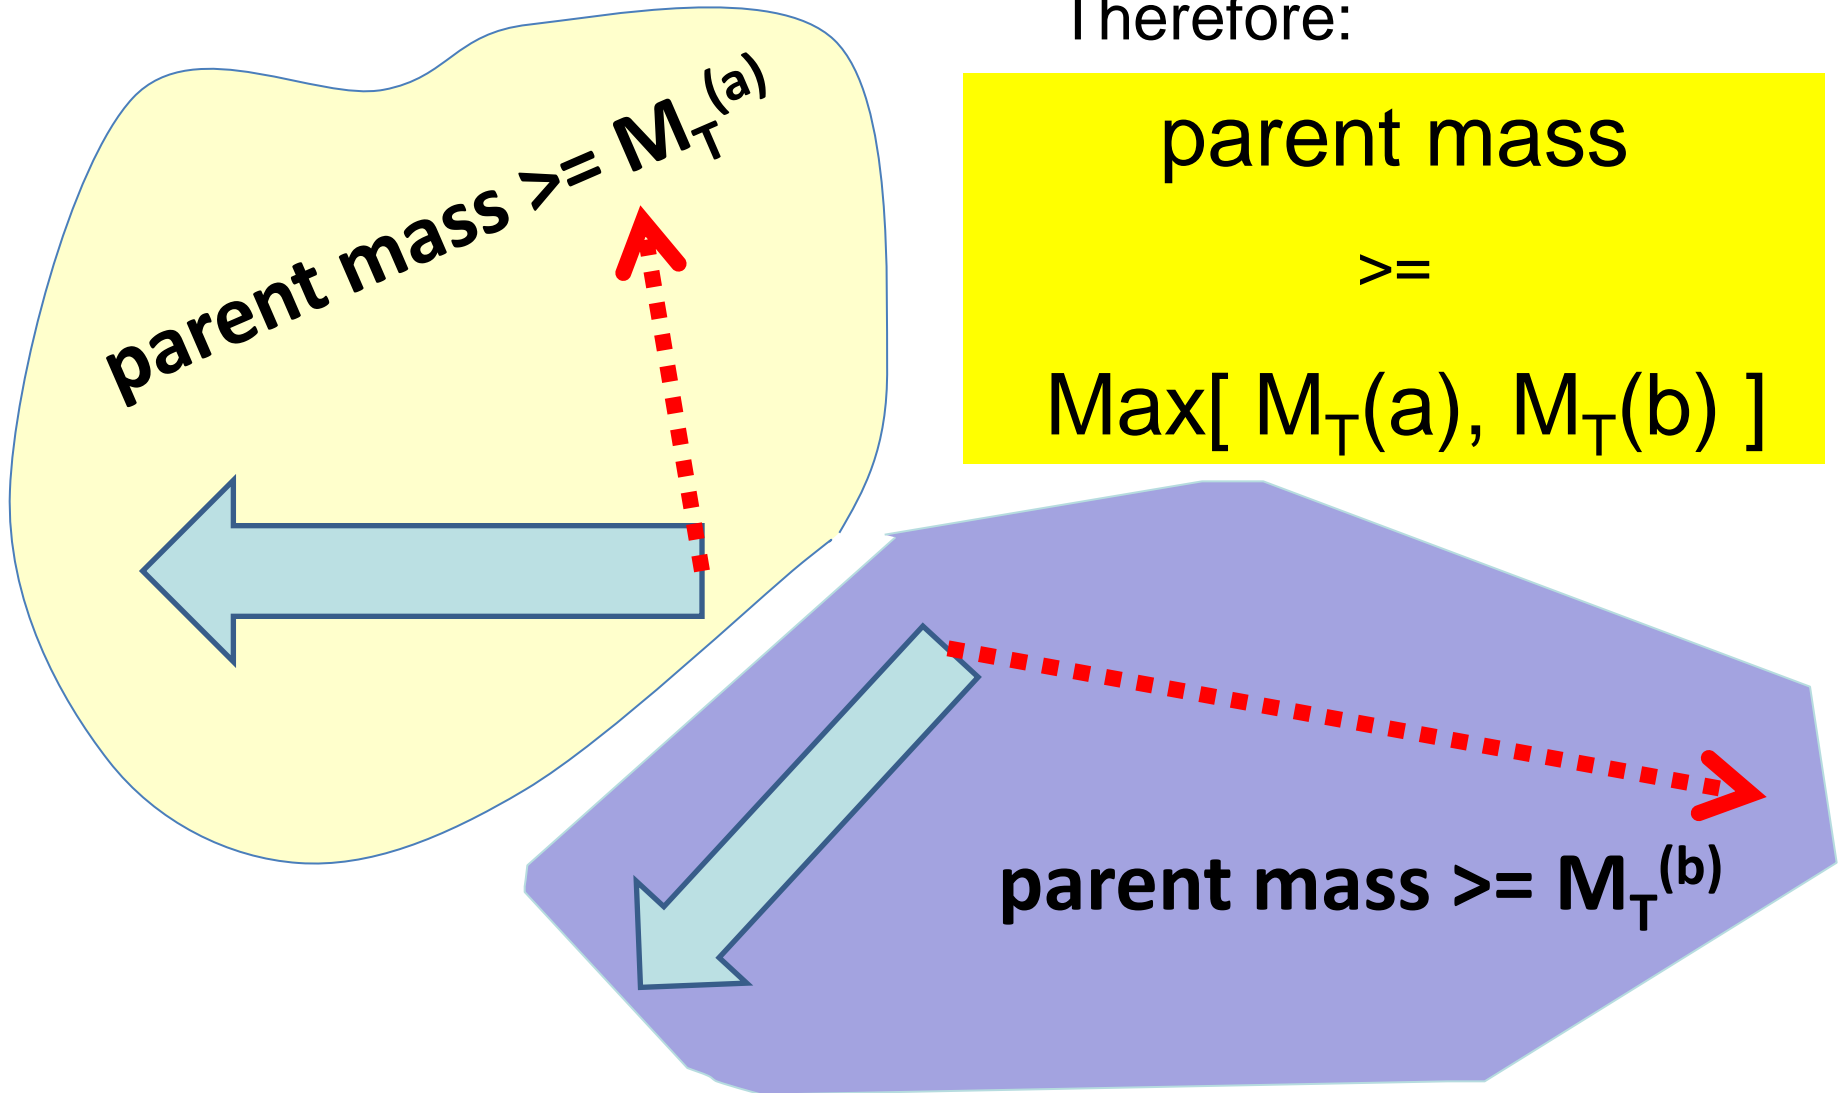

If this splitting is “correct”:

Therefore:

parent mass

\geq

$\text{Max}[M_T(a), M_T(b)]$

But this splitting **might be wrong!**

But can say that:

$$\text{parent mass} \geq \underset{\substack{\text{over all splittings} \\ \text{of } p_{\text{miss}}}}{\text{Min}} \{ \text{Max}[M_T(a), M_T(b)] \}$$

This is m_{T2} the “Stransverse Mass”

$$m_{T2}(v_1, v_2, \not{\mathbf{p}}_T, m_i^{(1)}, m_i^{(2)}) \equiv \min_{\sum \mathbf{q}_T = \not{\mathbf{p}}_T} \left\{ \max \left(m_T^{(1)}, m_T^{(2)} \right) \right\}$$

The most conservative
partition consistent with the
constraint

Take the better of the
two lower bounds

It is the generalisation of transverse mass to pair production.
Clear how to generalise it to any other types of production.

Note MT2 def is part of the four-step procedure:

[(1) select topology, (2) parent mass, (3) constraints, (4) find maximal lower bound]
described earlier.

Note, other approaches:
MCT, Rogan, etc.

CONSTRAINTS

$$\boxed{M_1 = M_2}$$

+

$$\boxed{\sum_{i=1}^{N_{\mathcal{I}}} \vec{q}_{iT} = \vec{p}_T \equiv -\vec{u}_T - \sum_{i=1}^{N_{\mathcal{V}}} \vec{p}_{iT}}$$

Momentum conservation in transverse plane

In other words:

- If your event is signal ...

and if MT_2 is “350 GeV” ...

then the squark mass is ≥ 350 GeV.

Indeed, can show MT_2 is, by construction, the **best possible** lower bound on the squark mass.

MT2 example in real data

- “Top Quark Mass Measurement using m_{T2} in the Dilepton Channel at **CDF**” (arXiv:0911.2956 and arXiv:1105.0192) reports that they “achieve **the single most precise measurement of m_{top} in [the dilepton] channel to date**”. Also under study by ATLAS.

Top-quark physics is an important testing ground for m_{T2} methods, both at the LHC and at the Tevatron. If it can't work there, its not going to work elsewhere.

Example MT2 distribution ...

... ?weighing? 500 GeV squarks

... works because M_{T2} for all BGs is provably low
 ... due to small QCD mass scale

All these have m_{T2} either $< m_{\text{top}}$ or $\rightarrow m_{\leq}$

Process	$m_{T2}(v_1, v_2, \cancel{p}_T, 0, 0)$	Comments
QCD di-jet \rightarrow hadrons	$= \max m_j$ by Lemmas 1, 4	
QCD multi jets \rightarrow hadrons	$= \max m_j$ by Lemma 4	
$t\bar{t}$ production	$= \max m_j$ by Lemma 4	fully hadronic decays
	$\leq m_t$ by Lemmas 1, 7	any leptonic decays
Single top / tW	$= \max m_j$ by Lemma 4	fully leptonic decays
	$\leq m_t$ by Lemmas 2, 7	any leptonic decays
Multi jets: "fake" \cancel{p}_T	$= \max m_j$ by Lemma 5	single mismeasured jet ^a
	$= \max m_j$ by Lemma 5	two mismeasured jets ^a
Multi jets: "real" \cancel{p}_T	$= \max m_j$ by Lemma 5	single jet with leptonic b decay ^a
	$= \max m_j$ by Lemma 6	two jets with leptonic b decays ^a
$Z \rightarrow \nu\bar{\nu}$	$= 0$ by Lemma 3	
$Z j \rightarrow \nu\bar{\nu} j$	$= \max m_j$ by Lemma 3	one ISR jet ^a
$W \rightarrow \ell\nu^b$	$= m_W$ by Lemma 3	
$W j \rightarrow \ell\nu j^b$	$\leq m_W$ by Lemma 2	one ISR jet ^a
$WW \rightarrow \ell\nu\ell\nu^b$	$\leq m_W$ by Lemma 1	
$ZZ \rightarrow \nu\bar{\nu}\nu\bar{\nu}$	$= 0$ by Lemma 3	also $= m_j$ for one ISR jet ^a
$LQ \bar{L}\bar{Q} \rightarrow q\nu\bar{q}\bar{\nu}$	$\leq m_{LQ}$	} i.e. can take large values
$\tilde{q}\tilde{\bar{q}} \rightarrow q\tilde{\chi}_1^0\bar{q}\tilde{\chi}_1^0$	$\leq m_{\tilde{q}}$	
$q_1, \bar{q}_1 \rightarrow q\gamma_1, \bar{q}\gamma_1$	$\leq m_{q_1}$	

So good for low multiplicity pair production signal discovery – dileptons?

Putting it to work for discovery

ATLAS EXPERIMENT

Run Number: 16777 Event Number: 20330190

Date: 2010-10-28 02:24:03 CEST

Health warning!

But note: high multiplicity environment already proving to be a challenge for mT2 (post 35/pb) and di-squark search in most recent data is being conducted with Meff. Problem is diagnosing the di-jet system.

Have dodged question of
mass of invisible daughters.

What if we don't know their
masses?

Varying “ χ ” ... to first order

Does not just
translate ...

**Shape may also
change** ... more
on this later.

MT2 inherits mass-space boundary from MT

The $m_{T2}(\chi)$ curve is the **boundary** of the region of (mother, daughter) **mass-space consistent** with the observed event!

Minimal Kinematic Constraints and $m(T2)$,
Hsin-Chia Cheng and Zhenyu Han (UCD)
e-Print: [arXiv:0810.5178 \[hep-ph\]](https://arxiv.org/abs/0810.5178)

MT2 is defined in terms of MT

- Consequently, MT2 inherits the “kink structure” of MT and can (in principle) be used to:
 - **EASILY** measure the parent-daughter mass difference,
 - might **PERHAPS** measure the absolute mass scale using utm boosts kinks or variable visible mass kinks (**HARD**)

Are MT2 kinks observable ?

Expect KINK only from
UTM Recoil (perhaps
only from ISR!)

Expect stronger KINK due to
both UTM recoil, AND variability
in the visible masses.

Perhaps: MT2's endpoint structure is weaker than MT's.

Caveat Mensor!

(for those of you interested in
LHC dark matter constraints)

Disappointingly, M_{T2} kinks, are the only known **kinematic** methods which (at least in principle) allow determination of the mass of the invisible daughters of pair produced particles in short chains.

[We will see a **dynamical** method that works for three+ body decays shortly. **Likelihood** methods can determine masses in pair decays too, though at cost of model dependence and CPU. See Alwall.]

change of topic!

Not all proposed new-physics chains are short!

(more details in [arXiv:1004.2732](https://arxiv.org/abs/1004.2732))

If chains a longer use “edges”
or “Kinematic endpoints”

Plot distributions of the
invariant masses of
what you can see

What is a kinematic endpoint?

- Consider M_{LL}

What is a kinematic endpoint?

- Zoom in on di-leptons to calculate m_{LL}

- In slepton rest-frame

$$m_{ll}^2 = (m_{ll}^{\text{max}})^2 (1 - \cos \theta) / 2$$

Dilepton invariant mass distribution

Note key difference to bounding vars

- With the bounding vars you **place a bound on** a property/parameter/invariant of the hypothesis or model by construction.
- With the kinematic edges and endpoints, you look for a kinematic structure in a distribution, and use it to **constrain one or more parameters** of the hypothesis or model.

What about these invariant masses?

Some extra difficulties – may not know order particles were emitted

Therefore need to define
order-blind variables
such as

$$m_{ql}^{high} = \max[m_{ql+}, m_{ql-}]$$

$$m_{ql}^{low} = \min[m_{ql+}, m_{ql-}]$$

$$m_{j\ell(s)}^2(\alpha) \equiv \left(m_{j\ell_n}^{2\alpha} + m_{j\ell_f}^{2\alpha} \right)^{\frac{1}{\alpha}} \quad m_{j\ell(d)}^2(\alpha) \equiv \left| m_{j\ell_n}^{2\alpha} - m_{j\ell_f}^{2\alpha} \right|^{\frac{1}{\alpha}}$$

There are many other possibilities for resolving problems due to position ambiguity.

Compare [hep-ph/0007009](#) and [hep-ph/0510356](#) with [arXiv:0906.2417](#)

Measure Kinematic Edge Positions

Determine how edge positions depend on particle masses

Related edge	Kinematic endpoint
$l+l^-$ edge	$(m_{ll}^{\max})^2 = (\tilde{\xi} - \tilde{l})(\tilde{l} - \tilde{\chi})/\tilde{l}$
$l+l^-q$ edge	$(m_{llq}^{\max})^2 = \begin{cases} \max \left[\frac{(\tilde{q}-\tilde{\xi})(\tilde{\xi}-\tilde{\chi})}{\tilde{\xi}}, \frac{(\tilde{q}-\tilde{l})(\tilde{l}-\tilde{\chi})}{\tilde{l}}, \frac{(\tilde{q}\tilde{l}-\tilde{\xi}\tilde{\chi})(\tilde{\xi}-\tilde{l})}{\tilde{\xi}\tilde{l}} \right] \\ \text{except for the special case in which } \tilde{l}^2 < \tilde{q}\tilde{\chi} < \tilde{\xi}^2 \text{ and } \\ \tilde{\xi}^2\tilde{\chi} < \tilde{q}\tilde{l}^2 \text{ where one must use } (m_{\tilde{q}} - m_{\tilde{\chi}_1^0})^2. \end{cases}$
Xq edge	$(m_{Xq}^{\max})^2 = X + (\tilde{q} - \tilde{\xi}) \left[\tilde{\xi} + X - \tilde{\chi} + \sqrt{(\tilde{\xi} - X - \tilde{\chi})^2 - 4X\tilde{\chi}} \right] / (2\tilde{\xi})$
$l+l^-q$ threshold	$(m_{llq}^{\min})^2 = \begin{cases} [2\tilde{l}(\tilde{q} - \tilde{\xi})(\tilde{\xi} - \tilde{\chi}) + (\tilde{q} + \tilde{\xi})(\tilde{\xi} - \tilde{l})(\tilde{l} - \tilde{\chi}) \\ -(\tilde{q} - \tilde{\xi})\sqrt{(\tilde{\xi} + \tilde{l})^2(\tilde{l} + \tilde{\chi})^2 - 16\tilde{\xi}\tilde{l}^2\tilde{\chi}}] / (4\tilde{l}\tilde{\xi}) \end{cases}$
$l_{\text{near}q}^{\pm}$ edge	$(m_{l_{\text{near}q}}^{\max})^2 = (\tilde{q} - \tilde{\xi})(\tilde{\xi} - \tilde{l})/\tilde{\xi}$
$l_{\text{far}q}^{\pm}$ edge	$(m_{l_{\text{far}q}}^{\max})^2 = (\tilde{q} - \tilde{\xi})(\tilde{l} - \tilde{\chi})/\tilde{l}$
$l^{\pm}q$ high-edge	$(m_{lq(\text{high})}^{\max})^2 = \max \left[(m_{l_{\text{near}q}}^{\max})^2, (m_{l_{\text{far}q}}^{\max})^2 \right]$
$l^{\pm}q$ low-edge	$(m_{lq(\text{low})}^{\max})^2 = \min \left[(m_{l_{\text{near}q}}^{\max})^2, (\tilde{q} - \tilde{\xi})(\tilde{l} - \tilde{\chi})/(2\tilde{l} - \tilde{\chi}) \right]$
M_{T2} edge	$\Delta M = m_{\tilde{l}} - m_{\tilde{\chi}_1^0}$

hep-ph/0007009

updated version at [arXiv:1004.2732](https://arxiv.org/abs/1004.2732)

Table 4: The absolute kinematic endpoints of invariant mass quantities formed from decay chains of the types mentioned in the text for known particle masses. The following shorthand notation has been used: $\tilde{\chi} = m_{\tilde{\chi}_1^0}^2$, $\tilde{l} = m_{\tilde{l}_R}^2$, $\tilde{\xi} = m_{\tilde{\chi}_2^0}^2$, $\tilde{q} = m_{\tilde{q}}^2$ and X is m_h^2 or m_Z^2 depending on which particle participates in the “branched” decay.

So now we have:

Large set of measurements

Endpoint	S5	
	Fit	Fit error
l^+l^- edge	109.10	0.13
l^+l^-q edge	532.1	3.2
$l^\pm q$ high-edge	483.5	1.8
$l^\pm q$ low-edge	321.5	2.3
l^+l^-q threshold	266.0	6.4
Xq edge	514.1	6.6
ΔM (M_{T2} edge)	—	—

Theoretical expressions for edge positions in terms of masses

Related edge	Kinematic endpoint
l^+l^- edge	$(m_{ll}^{\max})^2 = (\tilde{\xi} - \tilde{l})(\tilde{l} - \tilde{\chi})/\tilde{l}$
l^+l^-q edge	$(m_{llq}^{\max})^2 = \begin{cases} \max \left[\frac{(\tilde{q}-\tilde{\xi})(\tilde{\xi}-\tilde{\chi})}{\tilde{\xi}}, \frac{(\tilde{q}-\tilde{l})(\tilde{l}-\tilde{\chi})}{\tilde{l}}, \frac{(\tilde{q}-\tilde{\xi})(\tilde{\xi}-\tilde{l})}{\tilde{\xi}} \right] \\ \text{except for the special case in which } \tilde{l}^2 < \tilde{q}\tilde{\chi} < \tilde{\xi}^2 \text{ and } \tilde{\xi}^2\tilde{\chi} < \tilde{q}\tilde{l}^2 \text{ where one must use } (m_{\tilde{q}} - m_{\tilde{\chi}_1^0})^2. \end{cases}$
Xq edge	$(m_{Xq}^{\max})^2 = X + (\tilde{q} - \tilde{\xi}) \left[\tilde{\xi} + X - \tilde{\chi} + \sqrt{(\tilde{\xi} - X - \tilde{\chi})^2 - 4X\tilde{\chi}} \right] / (2\tilde{\xi})$
l^+l^-q threshold	$(m_{llq}^{\min})^2 = \begin{cases} [2\tilde{l}(\tilde{q} - \tilde{\xi})(\tilde{\xi} - \tilde{\chi}) + (\tilde{q} + \tilde{\xi})(\tilde{\xi} - \tilde{l})(\tilde{l} - \tilde{\chi})] \\ -(\tilde{q} - \tilde{\xi})\sqrt{(\tilde{\xi} + \tilde{l})^2(\tilde{l} + \tilde{\chi})^2 - 16\tilde{\xi}\tilde{l}^2\tilde{\chi}}] / (4\tilde{l}\tilde{\xi}) \end{cases}$
$l_{\text{near}}^\pm q$ edge	$(m_{l_{\text{near}}q}^{\max})^2 = (\tilde{q} - \tilde{\xi})(\tilde{\xi} - \tilde{l})/\tilde{\xi}$
$l_{\text{far}}^\pm q$ edge	$(m_{l_{\text{far}}q}^{\max})^2 = (\tilde{q} - \tilde{\xi})(\tilde{l} - \tilde{\chi})/\tilde{l}$
$l^\pm q$ high-edge	$(m_{lq}^{\max})^2 = \max \left[(m_{l_{\text{near}}q}^{\max})^2, (m_{l_{\text{far}}q}^{\max})^2 \right]$
$l^\pm q$ low-edge	$(m_{lq}^{\min})^2 = \min \left[(m_{l_{\text{near}}q}^{\max})^2, (\tilde{q} - \tilde{\xi})(\tilde{l} - \tilde{\chi})/(2\tilde{l} - \tilde{\chi}) \right]$
M_{T2} edge	$\Delta M = m_{\tilde{l}} - m_{\tilde{\chi}_1^0}$

Fit all edge position for masses!
...mainly constrain mass differences

Cross section information is orthogonal to mass differences

How applicable are these long chain techniques ?

For the chain $\tilde{q} \rightarrow q\tilde{\chi}_2^0 \rightarrow ql\tilde{l}_R \rightarrow qll\tilde{\chi}_1^0$
we need:

- $m_{\tilde{\chi}_2^0} > m_{\tilde{l}_R} > m_{\tilde{\chi}_1^0}$

- $m_{\tilde{g}} > m_{\tilde{q}}$

This is possible over a wide range of parameter space.

If this chain is not open, the method is still valid, but we need to look at other decay chains.

Example mSUGRA inspired scenario: $-A_0 = m_0$, $\tan \beta = 10$, $\mu > 0$

[See Allanach et al, Eur.Phys.J.C25 (2002) 113, hep-ph/0202233]

$\tilde{Q} \rightarrow D \tilde{\chi}_2^0$ or $\tilde{Q} \rightarrow u \tilde{\chi}_1^0$
 $\tilde{D} \rightarrow \bar{u} \tilde{\chi}_2^0$ or $\tilde{D} \rightarrow \bar{d} \tilde{\chi}_1^0$
 but other are impossible
 The hatched area is amenable
 to this method in some form.
 $m_{\tilde{l}_R} > m_{\tilde{\chi}_2^0} > m_{\tilde{\chi}_1^0}$

Its pretty hard to do 1
 iteration doesn't change much
 anything with this! 10
 for other mSUGRA inspired
 scenarios.

Figure from hep-ph/0410303

Other ambiguities

$$(m_{llq}^2)^{\max} = \begin{cases} (m_{\tilde{q}} - m_{\tilde{\chi}_1^0})^2 & \text{if } m_{\tilde{\chi}_2^0}^2 > m_{\tilde{q}} m_{\tilde{\chi}_1^0} \\ (m_{\tilde{q}}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{\chi}_2^0}^2 - m_{\tilde{\chi}_1^0}^2)/m_{\tilde{\chi}_2^0}^2 & \text{otherwise.} \end{cases}$$

hep-ph/0609298

Both look
the same
to the
detector

(Though shape differs
– see later)

Endpoints are not always linearly independent

e.g. if $m_{\tilde{q}_L} > m_{\tilde{\chi}_2^0}^2/m_{\tilde{\chi}_1^0}$ and $m_{\tilde{\chi}_1^0}^2 + m_{\tilde{\chi}_2^0}^2 > 2m_{\tilde{\chi}_1^0}m_{\tilde{\chi}_2^0} > 2m_{\tilde{q}_L}^2$

then the endpoints are

$$(m_{ll}^{\max})^2 = (m_{\tilde{\chi}_2^0}^2 - m_{\tilde{l}_R}^2)(m_{\tilde{l}_R}^2 - m_{\tilde{\chi}_1^0}^2)/m_{\tilde{l}_R}^2$$

$$(m_{qll}^{\max})^2 = (m_{\tilde{q}_L}^2 - m_{\tilde{l}_R}^2)(m_{\tilde{l}_R}^2 - m_{\tilde{\chi}_1^0}^2)/m_{\tilde{l}_R}^2$$

$$(m_{ql_n}^{\max})^2 = (m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{\chi}_2^0}^2 - m_{\tilde{l}_R}^2)/m_{\tilde{\chi}_2^0}^2$$

$$(m_{ql_f}^{\max})^2 = (m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{l}_R}^2 - m_{\tilde{\chi}_1^0}^2)/m_{\tilde{l}_R}^2$$

$$\Rightarrow (m_{qll}^{\max})^2 = (m_{ll}^{\max})^2 + (m_{ql_f}^{\max})^2$$

Four endpoints not always sufficient to find the masses

angle between
leptons in slepton
rest frame

- Introduce new distribution $m_{qll}^{\theta > \pi/2}$ identical to m_{qll} except require $\theta > \pi/2$

It is the **minimum** of this distribution which is interesting

Different parts of model space behave differently: m_{QLL}^{\max}

Where are the big mass differences?

$$(m_{llq}^{\max})^2 = \begin{cases} \max \left[\frac{(\tilde{q} - \tilde{\xi})(\tilde{\xi} - \tilde{\chi})}{\tilde{\xi}}, \frac{(\tilde{q} - \tilde{l})(\tilde{l} - \tilde{\chi})}{\tilde{l}}, \frac{(\tilde{q}\tilde{l} - \tilde{\xi}\tilde{\chi})(\tilde{\xi} - \tilde{l})}{\tilde{\xi}\tilde{l}} \right] \\ \text{except for the special case in which } \tilde{l}^2 < \tilde{q}\tilde{\chi} < \tilde{\xi}^2 \text{ and} \\ \tilde{\xi}^2\tilde{\chi} < \tilde{q}\tilde{l}^2 \text{ where one must use } (m_{\tilde{q}} - m_{\tilde{\chi}_1^0})^2. \end{cases}$$

Which parts of
 $(m^2_{q\text{lnear}}, m^2_{q\text{lfar}}, m^2_{\text{ll}})$ -space
 are populated by these events:

Answer: The Vegetable Samosa

Can see II edge clearly.

Can touch m_{llq} sphere at carrot corner

Can touch m_{llq} sphere at onion corner

Can touch m_{llq} sphere at noodle corner

Can touch m_{llq} sphere on the “front”

So, in principle, find masses by looking for highest contrast edge.

The “shadow” (projection) of the samosa is useful for origami too

Figure 7: Obtaining the shape of the $m_{jl(lo)}^2$ versus $m_{jl(hi)}^2$ bivariate distribution by folding the $m_{jl_n}^2$ versus $m_{jl_f}^2$ distribution across the line $m_{jl_n}^2 = m_{jl_f}^2$. This particular example applies to region \mathcal{R}_3 . For the other three regions, refer to Figs. 8(a), 8(b) and 8(d).

Formalising an old idea ... kinematic boundaries, creases, edges, cusps etc

FIG. 1: A schematic diagram describing the relation between the full phase space and the projected observable phase space.

Adding even more
assumptions ...

Let's consider what happens when we allow ourselves to look at more than one event

N successive 2-body decays

- In D space-time dimensions
- $D + (N+1)$ unknowns: comprising
 - D unknown momentum-components for final “missing particle”
 - $(N+1)$ unknown backbone-particle masses
- $N+1$ constraints:
 - Invariant masses of the backbone-momenta must match the “unknown” masses
- $\text{UNKNOWN} - \text{CONSTRAINTS} = D > 0$
 - Cannot solve for unknowns! ☹

Why not look at K events?

- K events, each (N successive 2-body decays)
- $KD + (N+1)$ **unknowns**: comprising
 - KD unknown momentum-components for final “missing particle”
 - $(N+1)$ unknown backbone-particle masses
- $K(N+1)$ **constraints**:
 - Invariant masses of the backbone-momenta must match the “unknown” masses
- $\text{UNKNOWN} - \text{CONSTRAINTS} = K(D - (N + 1)) + (N + 1)$
- System solvable for $K \geq \frac{N + 1}{N + 1 - D}$ provided $N + 1 > D$ i.e. $N \geq 4$.

Ambiguities

- Which jet is which?
- Which lepton is which?

- So **will need more events** than the last calculation suggests $\sim \times 4$?

“Mass relation” method: summary

- Can:
 - reconstruct complete decay kinematics
 - Measure all sparticle masses
- provided that:
 - Chain has $N \geq 4$ successive two-body decays
 - One **simultaneously examines at least**

$$\frac{N + 1}{N + 1 - D} = \frac{N + 1}{N - 3}$$

events sharing the same sparticles.

Some example reconstructed masses

(100 events, toy MC)

Caveats: Though see Miller
hep-ph/0501033

Nobody has shown that this
will work for real data.

Sample purity. Bias.
Heavily model dependent?

Dependence on reconstruction resolution.

N=4 two-body decays

- Fewer than 5 events
 - Under constrained, cannot solve
- 5 events
 - Can solve in principle (ignoring ambiguities)
 - Can treat events as “ideal”
- More than 5 events
 - Over constrained. Potential for inconsistency.
 - Reconstructed events will not “make sense” until resolutions are taken into account.

Another sort of “just”-constrained event

– get constraint from other “side”

Left: case considered
in hep-ph/9812233

- Even if there are invisible decay products, events can often be fully reconstructed if decay chains are long enough.
- (mass-shell constraints must be \geq unknown momenta)
- Since we can use p_{miss} constraint, chains can be shorter than $N=4$ now.

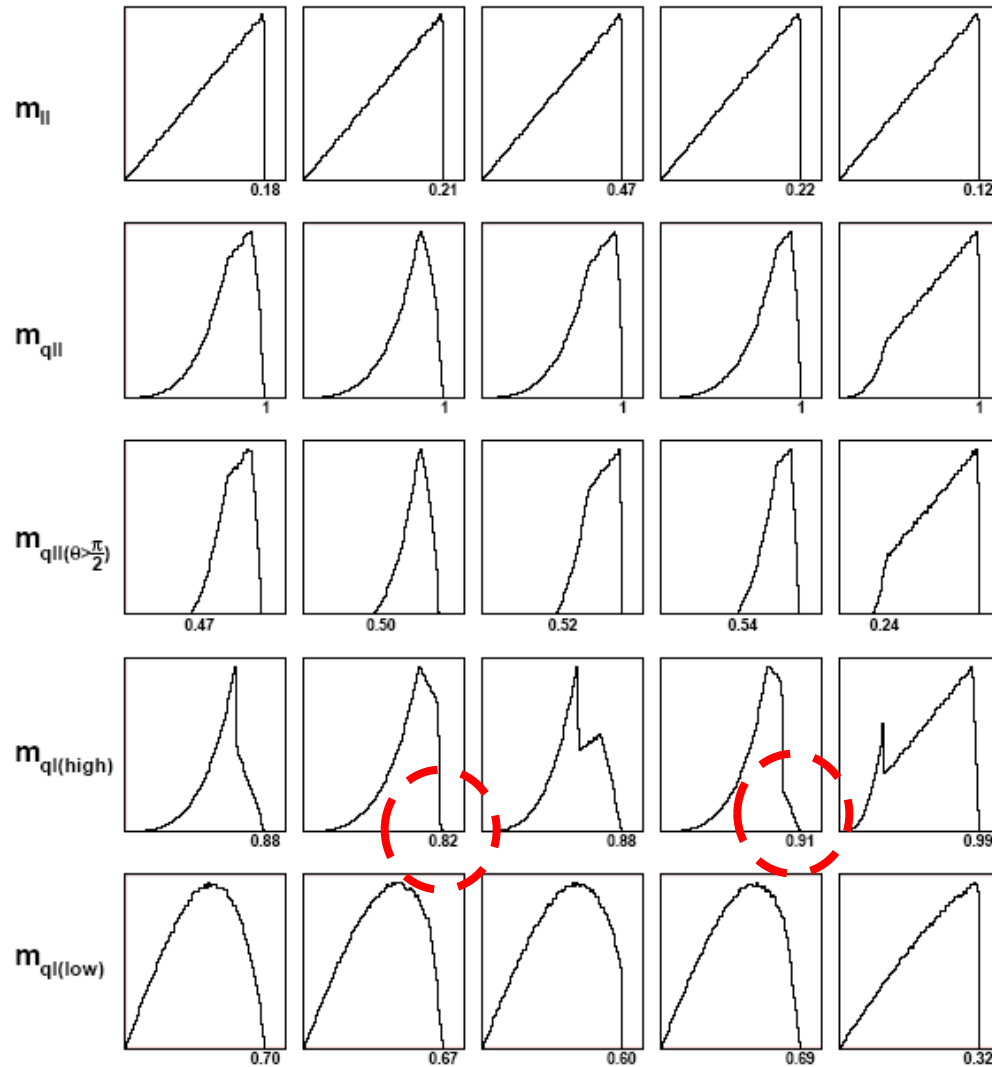

Or do both at once
– pairs of double events!

- Pairs of events
of the form:

are **exactly** constrained.
(arXiv:0905.1344)

What about shapes of distributions?

Gjelsten, Miller, Osland: hep-ph/0410303

Compare shapes of invariant mass distributions for the highlighted pairs of visible massless momenta:

versus

One piece of information (the endpoint position) is not sufficient to determine M_A , M_B and M_C .

Shape has dependence on M_A and M_B .

Do we have enough information from shape alone to find M_A and M_B in this three body decay, then?

Yes and no ..

- Putting aside experimental fears concerning efficiency and acceptance corrections ...
- ... huge errors in the fit, and very poor sensitivity to absolute mass scale. See next exercises.
- This is why endpoints, edges and resonances are good, but shapes less so

Exercises

- (12) Determine the shape of the phase space distribution $d\sigma/d(mll)$ (up to an arbitrary normalizing constant) for the three-body decay shown below. Assume massless visibles, and arbitrary masses for the parent and invisible.

- (13) Prove that $r=x/y$ must lie in the range $1/\sqrt{3} \leq r \leq 1/\sqrt{2}$. (Note this means r can only move by ± 0.06 ... not far!)

- (14) Estimate how many events (approximately) would be needed to distinguish two r values differing by 0.012 (i.e. $\sim 1/10^{\text{th}}$ of allowed range)

At fixed $M_A - M_B$ you should find

The most detailed “shape” of all is the complete likelihood of the data

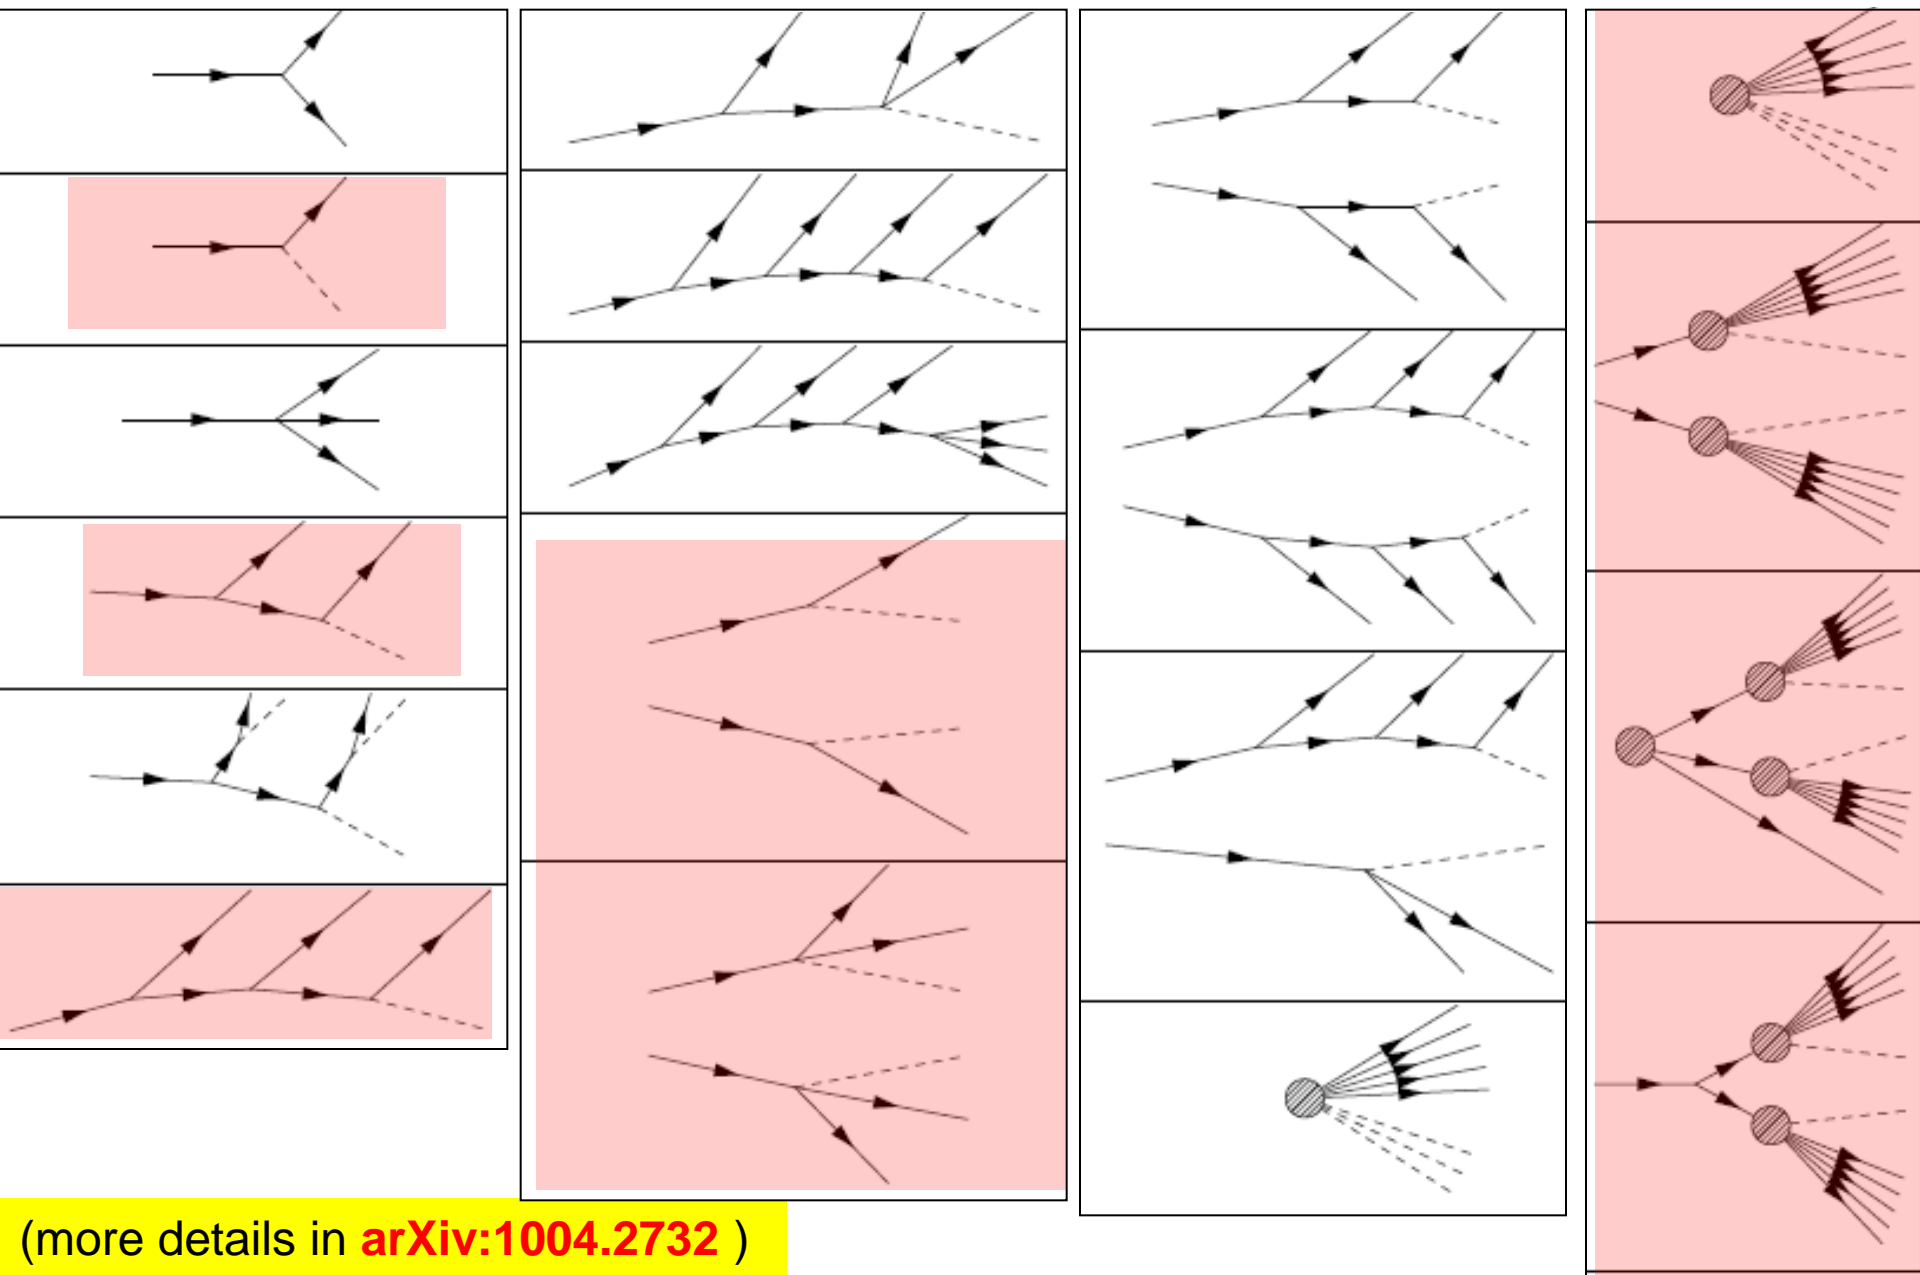

- Alwall et.al. (arXiv:0910.2522, arXiv:1010.2263) applied matrix element method to:

- For ~ 100 events get valley in likelihood surface with same shape as boundary of M_{T2} distribution

That's probably enough on mass
measurement techniques!

Have only begun to scrape the surface.

(more details in **arXiv:1004.2732**)

Not time to talk about many things

- Parallel and perpendicular MT2 and MCT
- Subsystem MT2 and MCT methods
- Solution counting methods (eg arXiv:0707.0030)
- Hybrid Variables
- Phase space boundaries (arXiv:[0903.4371](#))
- Cusps and Singularity Variables (Ian-Woo Kim)
- Why wrong solutions are often near right ones (arXiv:1103.3438)
- Razors
- and many more!

I have only scratched the surface of the variables that have been discussed. Even the review of mass measurement methods arXiv:1004.2732 makes only a small dent in 70+ pages. However it provides at least an index ...

Take home messages

- **Lots** of approaches to kinematic mass measurement
 - some very general, some very specific.
 - very little of the “detailed stuff” is tested in anger. Experimentalists not universally convinced of utility!
 - very often BGs present serious impediment.
 - theorists and experimenters should pay close attention to zone of applicability
- **BUT**
 - Finding sensible variables buys more than just mass measurements - e.g. signal sensitivity

Extras if time ...

Notes:

- At TASI 2010: 75 mins per lecture:
- Lec1: 1-73 (73 slides)
- Lec2: 74-183 (110 slides)
- Lec3: 184-224 (41 slides) on masses
 - then segue into spins for another 40

Other MT2 related variables (1/3)

- **MCT** (“Contralinear-Transverse Mass”)

(arXiv:0802.2879)

- Is equivalent to MT2 in the special case that there is no missing momentum (and that the visible particles are massless).
- Proposes an interesting multi-stage method for measuring additional masses
- Can be calculated fast enough to use in ATLAS trigger.

Other MT2 related variables (2/3)

- **MTGEN** (“MT for GENeral number of final state particles”) (arXiv:0708.1028)
 - Used when
 - each “side” of the event decays to MANY visible particles (and one invisible particle) and
 - it is not possible to determine which decay product is from which side ... all possibilities are tried
- **Inclusive or Hemispheric MT2** (Nojirir + Shimizu) (arXiv:0802.2412)
 - Similar to MTGEN but based on an assignment of decay product to sides via hemisphere algorithm.
 - Guaranteed to be \geq MTGEN

Other MT2 related variables (3/3)

- **M2C** (“MT2 Constrained”) arXiv:0712.0943 (wait for v3 ... there are some problems with the v1 and v2 drafts)
- **M2CUB** (“MT2 Constrained Upper Bound”) arXiv:0806.3224
- There is a sense in which these two variables are really two sides of the same coin.
 - if we could re-write history we might name them more symmetrically
 - I will call them m_{Small} and m_{Big} in this talk.

m_{Small} and m_{Big}

- Basic idea is to **combine**:

– **MT2**

- with

- a **di-lepton invariant mass endpoint** measurement (or similar) providing:

$$\Delta = M_A - M_B$$

(or $M_Y - M_N$ in the notation of their figure above)

“Best case”

(needs SPT, i.e. large recoil PT)

Both m_{Big} and m_{Small} are found.

“Typical ZPT case”
(no m_{Big} is found)

“Possible ZPT case”
(neither m_{Big} nor m_{Small} is found)*

* Except for conventional definition of m_{Small} to be Δ in this case.

“Possible SPT case”
(no m_{Small} is found)*

* Except for conventional definition of m_{Small} to be Δ in this case.

What m_{Small} and m_{Big} look like, and how they determine the parent mass

Outcome:

- m_{Big} provides the **first potentially-useful event-by-event upper bound for m_A**
 - (and a corresponding event-by-event upper bound for m_B called $m_{\chi_{\text{UB}}}$)
- m_{Small} provides a **new kind of event-by-event lower bound for m_A** which incorporates consistency information with the dilepton edge
- **m_{Big} is always reliant on SPT** (large recoil of interesting system against “up-stream momentum”) – cannot ignore recoil here!

LHC Specific problems

- Hadron Collider – z-boost of COM unknown
- Pile up, multiple interactions
- Production of many new particles at once?
- Multiple massive stable invisible particles?

What sort of parameter spaces?

- High dimensional
- At the very least, 8 dims
- More like ~ 100 dims
- No really compelling reasons to believe in any particular simple model

<ul style="list-style-type: none">• m_0• $M_{1/2}$• A_0• Tan beta• $\text{Sgn } \mu$	SUSY params
<ul style="list-style-type: none">• m_b• m_t• $\alpha_s(M_Z)$	SM params

Unusual parameter spaces!

Shape of typical set is often something quite horrible.

Contrast with UA1/UA2

- Glashow Wienberg Salam: Phys Rev Lett 19, 1264 (1967)
 - Predictions in terms of (then) unknown θ_W :
 - $M_Z > 75 \text{ GeV}/c^2$, $M_W > 35 \text{ GeV}/c^2$
- By 1982 θ_W much constrained, giving:
 - $M_Z \approx 92 \pm 2 \text{ GeV}/c^2$, $M_W \approx 82 \pm 2 \text{ GeV}/c^2$
- CERN able to build UA1+UA2 (~1980) knowing the above.
- In 1983 UA1+UA2 observe W and Z at expected masses:
 - $M_Z \approx 95 \pm 3 \text{ GeV}/c^2$, $M_W \approx 81 \pm 5 \text{ GeV}/c^2$

A personal view of some of the recent ATLAS results

(unashamed focus on new physics searches)

Contact interactions

Fermi theory **example**:

At low energies, this

looked like this:

... but now know that G_F is order one coupling suppressed by powers of W mass.

$$\frac{G_F}{(\hbar c)^3} = \frac{\sqrt{2}}{8} \frac{g^2}{m_W^2}$$

Can do the same sort of thing for “**four quark vertex**” to constrain new mass scale.

3.4 TeV contact interactions were excluded by 3/pb of data (95% CL)

qqqq contact interactions
peak at small jet-jet rapidity differences

SM QCD is mostly flat in jet-jet rapidity difference

y_1 and y_2 are rapidities of the two jets.

qqqq limit increases to 9.5 TeV with 36/pb
(Mar 2011: arXiv:1103.3864)
and

qqμμ limit is at 4.5 TeV with 42/pb
(April 2011: arXiv:1104.4398)

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

Highest Meff event so far

The highest Meff in any (supposedly “clean”) ATLAS event is 1548 GeV

– calculated from four jets with pts:

- 636 GeV
- 189 GeV
- 96 GeV
- 81 GeV

– 547 GeV of missing transverse momentum.

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

MSUGRA/CMSSM: $\tan\beta = 10$, $A_0 = 0$, $\mu > 0$

Latest ATLAS 0-lepton, jets, missing
transverse momentum data.

Less well tested areas

- neutralino mass close to squark or gluino mass
- signatures with not many jets

So far MT2 only competitive at 35/pb

Multi-leptons (with jets and MPT)

- Require 3 leptons (any flavour and charge combos)
 - 20 GeV electron/muon
 - 20 GeV electron/muon
 - 20 GeV electron / 10 GeV muon
- Require 2 jets > 50 GeV and MPT > 50 GeV to suppress $t\bar{t}$ and Z +jets
 - so not sensitive to direct multilepton production.

Multi-leptons

Multi-leptons

Multi-leptons

- Your favourite multi-lepton producing model is probably not ruled yet, unless you know it makes lots of jets too ...

Excesses in e^+e^- or $\mu^+\mu^-$ over $e^+\mu^-$ and $e^-\mu^+$?

- Can we focus on flavour-conserving BSM signals, and reduce sensitivity to BG modelling?

$$\mathcal{S} = \frac{N(e^\pm e^\mp)}{\beta(1 - (1 - \tau_e)^2)} - \frac{N(e^\pm \mu^\mp)}{1 - (1 - \tau_e)(1 - \tau_\mu)} + \frac{\beta N(\mu^\pm \mu^\mp)}{(1 - (1 - \tau_\mu)^2)}$$

<http://arxiv.org/abs/1103.6208>

	$e^\pm e^\mp$	$e^\pm \mu^\mp$	$\mu^\pm \mu^\mp$
Data	4	13	13
$Z/\gamma^* + \text{jets}$	0.40 ± 0.46	0.36 ± 0.20	0.91 ± 0.67
Dibosons	0.30 ± 0.11	0.36 ± 0.10	0.61 ± 0.10
$t\bar{t}$	2.50 ± 1.02	6.61 ± 2.68	4.71 ± 1.91
Single top	0.13 ± 0.09	0.76 ± 0.25	0.67 ± 0.33
Fakes	0.31 ± 0.21	-0.15 ± 0.08	0.01 ± 0.01
Total SM	3.64 ± 1.24	8.08 ± 2.78	6.91 ± 2.20

Aim is that analysis doesn't really need to know these numbers very well:

2lepton flavour subtraction :

If the assumption is made that the branching fractions for $e^\pm e^\mp$ and $\mu^\pm \mu^\mp$ final states in new physics events are identical, and the branching fraction for $e^\pm \mu^\mp$ final states is zero, a limit $\bar{\mathcal{S}}_s < 8.8$ is set at 95% confidence level. Al-

i.e. lepton flavour conserving limit of order 10 events for order 35 events/pb indicates **limit for cross section for lepton flavour conserving production is about ~ 0.3 pb**

<http://arxiv.org/abs/1103.6208>

fairly model independent

competitive with results from the jets+mpt analysis:

Exclude non-SM effective cross sections ($\sigma \times \text{BR} \times \text{Acc} \times \text{Eff}$):

A: 1.3 pb B: 0.35 pb C: 1.1 pb D: 0.11 pb

https://atlas.web.cern.ch/Atlas/GROUPS/PHYSICS/PAPERS/susy-0lepton_01/

.. competitive with 35/pb limits on strong BSM production

Exclude non-SM effective cross sections ($\sigma \times \text{BR} \times \text{Acc} \times \text{Eff}$):

A: 1.3 pb B: 0.35 pb C: 1.1 pb D: 0.11 pb

https://atlas.web.cern.ch/Atlas/GROUPS/PHYSICS/PAPERS/susy-0lepton_01/

This presentation arguably less
helpful.
