ABSTRACT

We report the first direct observation of neutrino interactions at a particle collider experiment. Neutrino candidate events are identified in a 13.6 TeV center-of-mass energy pp collision dataset of 35.4fb^{-1} using the active electronic components of the FASER detector at the Large Hadron Collider. The candidates are required to have a track propagating through the entire length of the FASER detector and be consistent with a muon neutrino charged-current interaction. We infer 153^{+12}_{-13} neutrino interactions with a significance of 16 standard deviations above the background-only hypothesis. These events are consistent with the characteristics expected from neutrino interactions in terms of secondary particle production and spatial distribution, and they imply the observation of both neutrinos and anti-neutrinos with an incident neutrino energy of significantly above 200 GeV.

Introduction

Most people believe physics beyond SM due to:

- no explanation of dark matter, neutrino mass, baryon asymmetry..
- theoretical issues, like hierarchy problem, quantum gravity,

Also, intensive discussion on several experimental anomalies:

- muon g-2, flavor anomaly, W mass...

Discovery of a new particle followed by detailed measurement must help this situation

- LHC has been a great energy-frontier collider, which could both produce and detect new particles
- however optimistic scenario used for designing experiments has not been successful
 - e.g, SUSY should have discovered already in LHC Run 1 (2010-)
- I joined ATLAS experiment in 2012, and also started FASER experiment in 2018.

New challenge would be definitely needed !

FASER experiment

FASER is a new forward experiment of LHC, located 480 m downstream from the ATLAS IP. **Successfully** started data taking in Run 3 from July 2022 for:

- Search for new weakly-coupled particles in the MeV-GeV range
 - proposed to CERN in 2018, approved by CERN in 2019
- Study of all flavors of neutrinos at the TeV-energy frontier
 - proposed to CERN in 2019, approved by CERN in 2020

Favorable location, except that refurbishment is needed to be an experimental site.

- Background from collision point is only high-energy muon at about $1 / \text{cm}^2 / \text{sec}$, thanks to $\sim 100\text{-m}$ rock
- Radiation level from LHC is quite low, around $4 \times 10^{-3} \text{ Gy/year}$ ($= 4 \times 10^7 \text{ 1-MeV neutron/cm}^2 / \text{year}$)

2021 Nov: LHC neutrino candidates (2.7 σ)

Searching for new particles in MeV-GeV range

Motivated by dark matter

- Example is a **dark photon** (A') – vector portal to dark sector
- Could be produced very **rarely** in decay of a π^0
- Could be **long-lived** due to small coupling constant

Huge flux of π^0 produced in LHC collision provides strong opportunity

- $O(10^{15})$ of π^0 in FASER acceptance ($r = 10$ cm) in Run 3
 - corresponding to 10^{-8} solid angle
- Very energetic - typically $E > 1$ TeV

Dark photon (A') decays into a collimated pair of charged particle

- $m_{A'} = 200$ MeV and $E = 2$ TeV, the separation is **$O(200)$ um** at the first tracker
- $e^+ e^-$ for most of the $m_{A'}$ range relevant for FASER

Searching for new particles in MeV-GeV range

FASER is the first far collider experiment for new particle searches

- Unique approach provides sensitivity to unexplored region with **the first 1 fb^{-1}** of the LHC collision

LHC finished the 2022 operation end of November

- About **40 fb^{-1}** delivered at the ATLAS interaction point
- FASER successfully collected the data
 - 96.1% delivered lumi recorded
 - red arrow: emulsion exchanged
 - green arrow: calo gain optimized

FASER will also have sensitivity to other dark sector scenarios including ALPs, other gauge bosons, ...

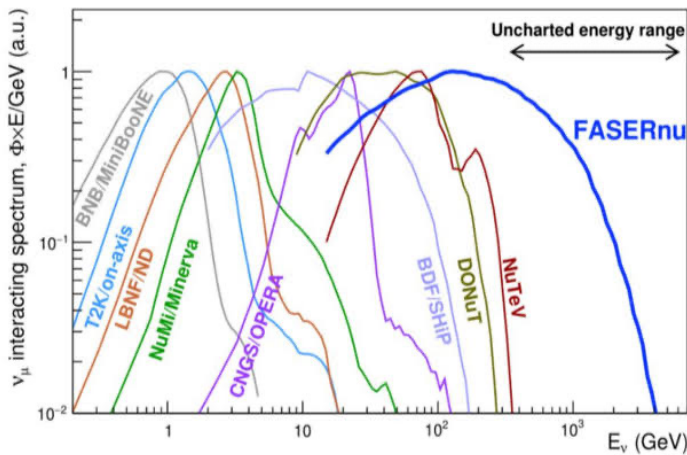

- Comprehensive summary found in [Phys. Rev. D 99, 095011 \(2019\)](#)

Exploring neutrinos at the TeV-energy frontier

Sensitive to new physics by measuring scattering cross sections and studying the final states

- Expected number of CC neutrino interaction with 250 fb^{-1} in Run 3

based on [PhysRevD.104.113008](https://arxiv.org/abs/1308.1308)

- Emulsion detector provides great ID for **all leptons** and **heavy flavor hadrons** from neutrino interaction

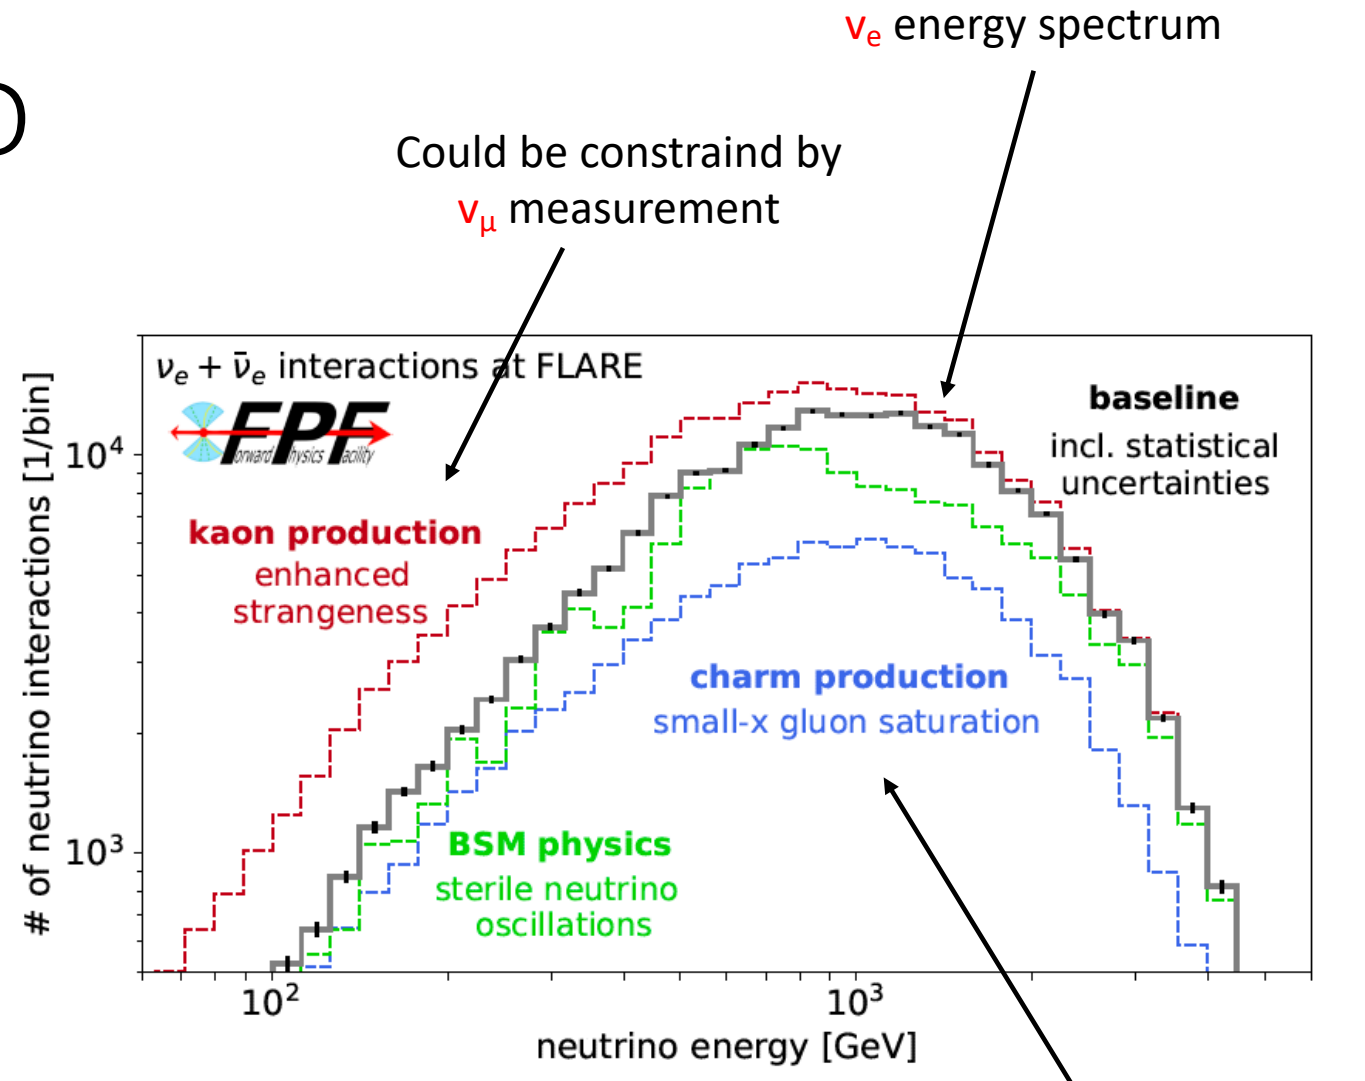

Breakdown of the LHC neutrino production

A new approach to measure proton PDFs (Parton Distribution Function)

- Gluon saturation
- Strange quark
- Charm quark

Unique inputs to QCD

Important to have good energy resolution of ν_e , ν_μ , ν_τ

- Combined measurements with Emulsion, tracker and calorimeter (see next pages)

FASER spectrometer (magnets and tracker), scintillators and calorimeter

April 2021

Emulsion/Tungsten detector, IFT and scintillator

March 2022

Emulsion/Tungsten detector

All flavors of neutrino interactions can be identified

- Heavy quark production also can be distinguished
- **730** x 1.1-mm-thick tungsten plates, interleaved with emulsion films
- 25 x 30 cm², 1.1 m long, **1.1 ton** detector ($220 X_0 / 8 \lambda_{int}$)
 - $\sim 10000 \nu_\mu$, $\sim 1000 \nu_e$ and $\sim 10 \nu_\tau$ expected in Run 3
- **3 replacements** each year
 - emulsion will be produced a few months before installation

Magnet system

The magnets were designed, constructed and measured by the CERN magnet group

Three 0.57 T permanent dipole magnets (1.5m-long x 1 and 1m-long x 2)

- Sufficient magnetic field to **separate a pair of charged particles**, assuming tracking detectors with good resolution
- Compact and robust design adapted to cope with limited space in the tunnel and limited access during Run3
- The assembled dipoles were measured with single-stretched wire (SSW) and 3D Hall probe mapper

Magnet	Dipole 1 (short)	Dipole 2 (short)	Dipole 3 (long)	Unit
$\int B_x dl$	-0.57692	-0.57840	-0.86150	Tm
$\int B_y dl$	0.00021	0.00040	-0.00250	Tm
Roll Angle	1.57045	1.57008	1.57366	rad

Target for neutrino

Decay volume of new particles

Tracker station

ATLAS SCT module:

- 6cm x 12cm x 2 sides (40 mrad)
- 80 μm pitch/ 768 strips per side
- Resolution: 17 μm x 580 μm
- 6 ASICs per side

Four stations; one station as an interface tracker to emulsion detector and three stations for spectrometer

- Based on ATLAS SCT modules - 4 stations x 3 layers x 8 modules = 96 modules

Tracker plane

Tracker station

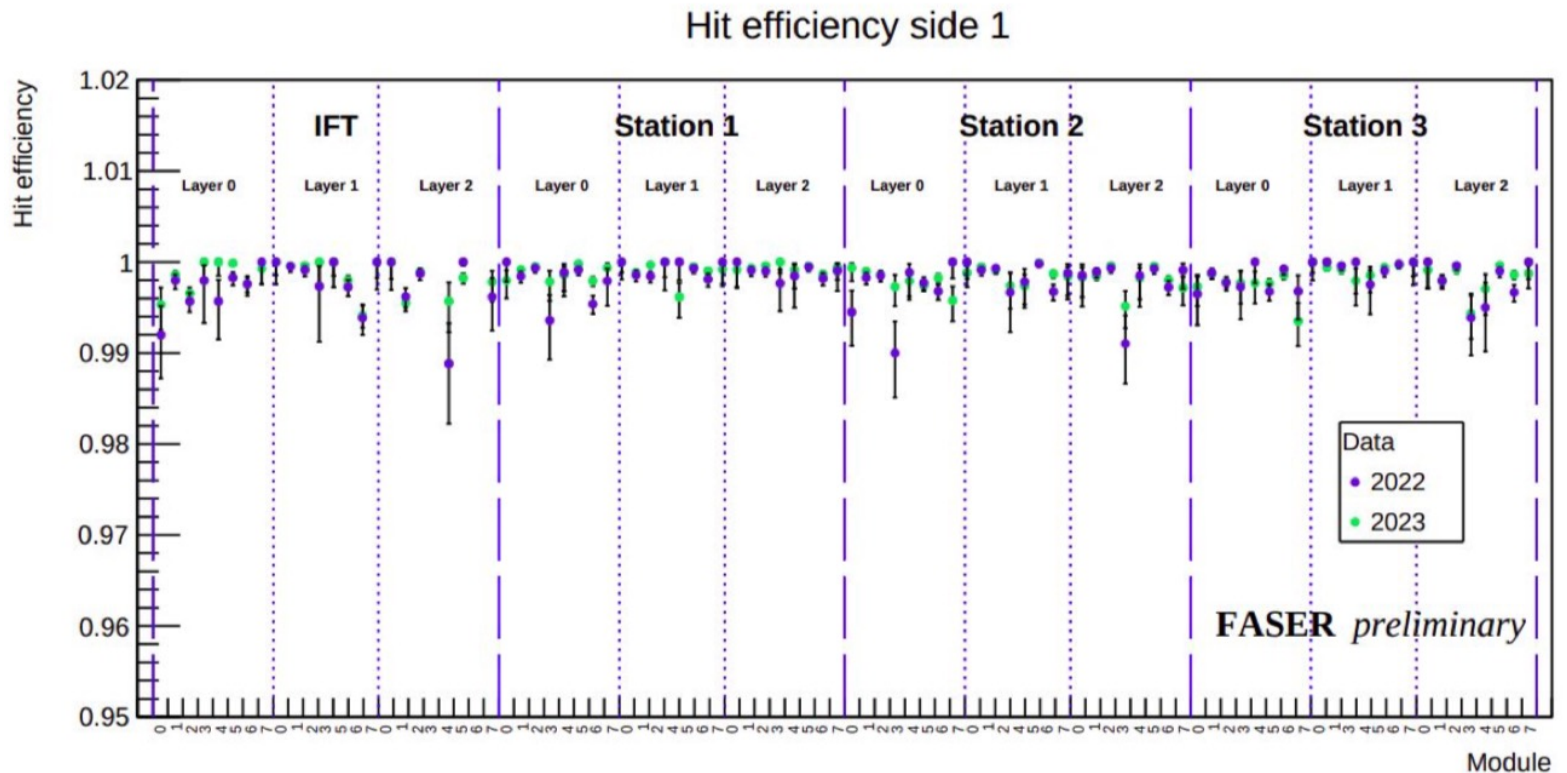

Target for neutrino

Decay volume of new particles

Tracker station performance

Hit efficiency of $99.64 \pm 0.10\%$ at 1.0 fC threshold and 150V

- 99.7% strips are active
- Consistent performance to ATLAS SCT

Scintillation detectors

Four scintillator stations are assembled and installed

- Veto incoming charged particle, precise timing, and pre-shower for calorimeter
- Scintillators, light guides and PMT housing constructed at CERN scintillator lab (EP-DT)

Scintillator	Efficiency
NuVeto-0	0.9999805(5)
NuVet0-1	0.9999810(5)
Veto-0	0.9999985(1)
Veto-1	0.9999984(1)
Veto-2	0.9999986(1)

Scintillator performance

More than 99.99% efficiency achieved for each scintillator, resulting in veto inefficiency less than 10^{-12}

- $O(10^8)$ muon expected in Run3 would be rejected; sufficient for zero background in new particle searches

Trigger scintillator provides timing resolution of 423 ps, sufficient to identify bunch crossing ID of LHC

- Average time of two PMTs on both ends of the trigger scintillator to correct for timewalk

Electromagnetic calorimeter

Calorimeter utilizes spare LHCb ECAL module x 4

- one module has:
 - 12 cm x 12 cm x 75 cm ($25 X_0$)
 - 66 layers of (2mm lead and 4mm scintillator)

EM Calorimeter – performance

LHC collision data shows calorimeter provides timing resolution of 256 ps, requiring:

- EM energy is above 4 GeV
- only events with unsaturated PMT signals
- BCID to be consistent with a colliding bunch ID

Close to the intrinsic 239 ps timing resolution of the LHC

Stable data taking throughout 2022

The number of bunches in LHC has reached 2400 since August 2022

- Maximum trigger rate around **1.2 kHz**, giving dead time less than **2%**
- Physics coincidence trigger (foremost veto and the preshower scintillator station) around **200Hz**
 - our main triggered background is not muons passing through from IP1 but particles triggering individual trigger stations

- only 850 pb^{-1} (**< 2.5%** of full dataset) data lost due to operational issues

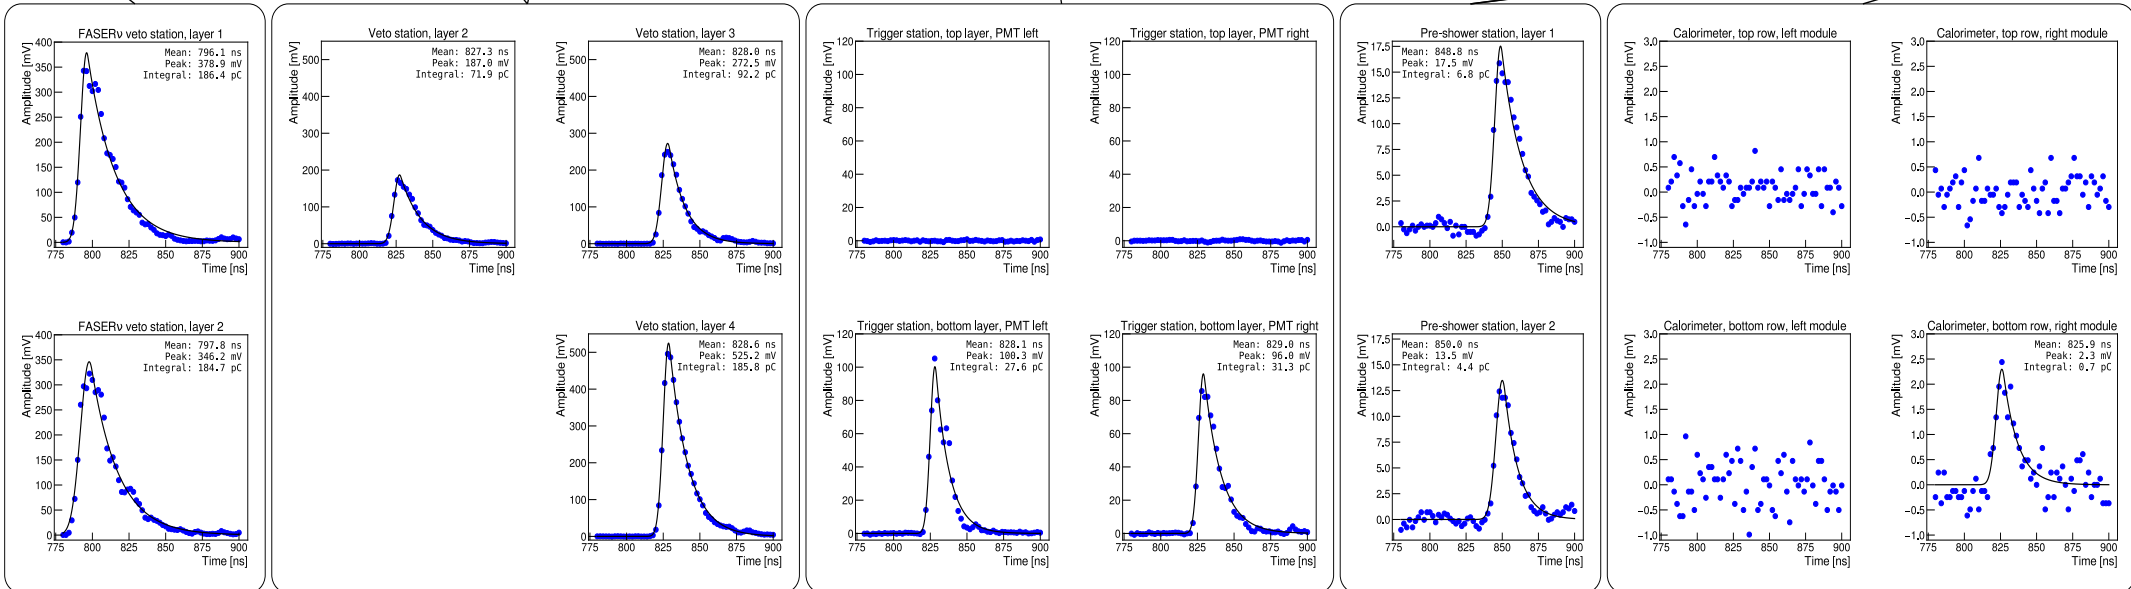

Muon event from LHC collision

Run 8336

Dark photon search

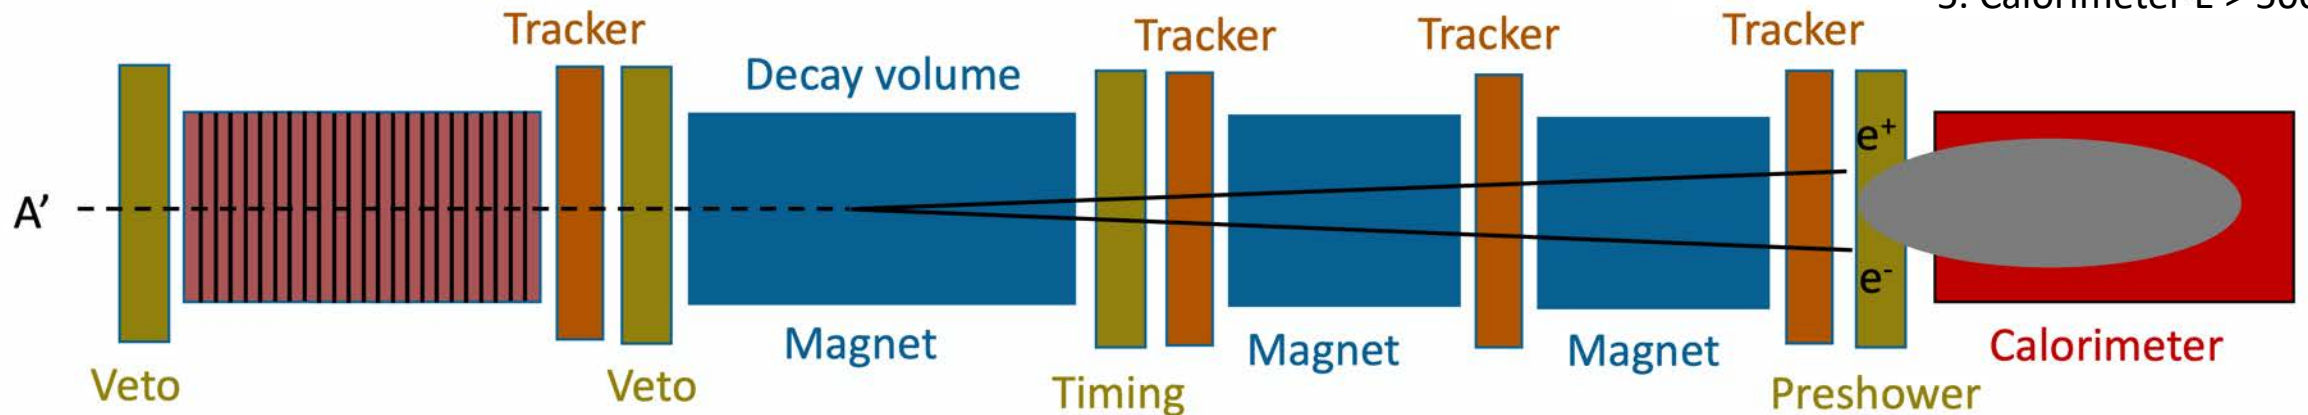

Analysis was **blinded** for $E > 100$ GeV events **without any veto signals**

Signal: select e^+e^- pairs appearing in the decay volume

1. Events in collision crossing, during good physics data period

3. Timing and preshower scintillators consistent with ≥ 2 MIPs

5. Calorimeter $E > 500$ GeV

2. No signal in any of veto scintillators (< 40 pC ~ 0.5 MIP)

4. Exactly two good quality tracks with $p > 20$ GeV
- Both tracks in fiducial tracking volume, $r < 95$ mm
 - Both tracks extrapolate to $r < 95$ mm in veto scintillators

Background estimation

Major background - Neutrino background

- Estimated from Genie simulation (300 ab⁻¹)
 - Uncertainties from neutrino flux & mismodeling
- Predicted events with E(calor)>500GeV: **0.0018±0.0024 events**
 - *Largest background in analysis*

Minor backgrounds

- Neutral hadrons (e.g. Ks) from upstream muons interacting in decay volume : **(2.2±3.1)×10⁻⁴ events**
- Veto inefficiency: negligible
- Non-collision background: negligible

Result

No events seen in unblinded signal region

- Total background: **0.0020 ± 0.0024 evts,**

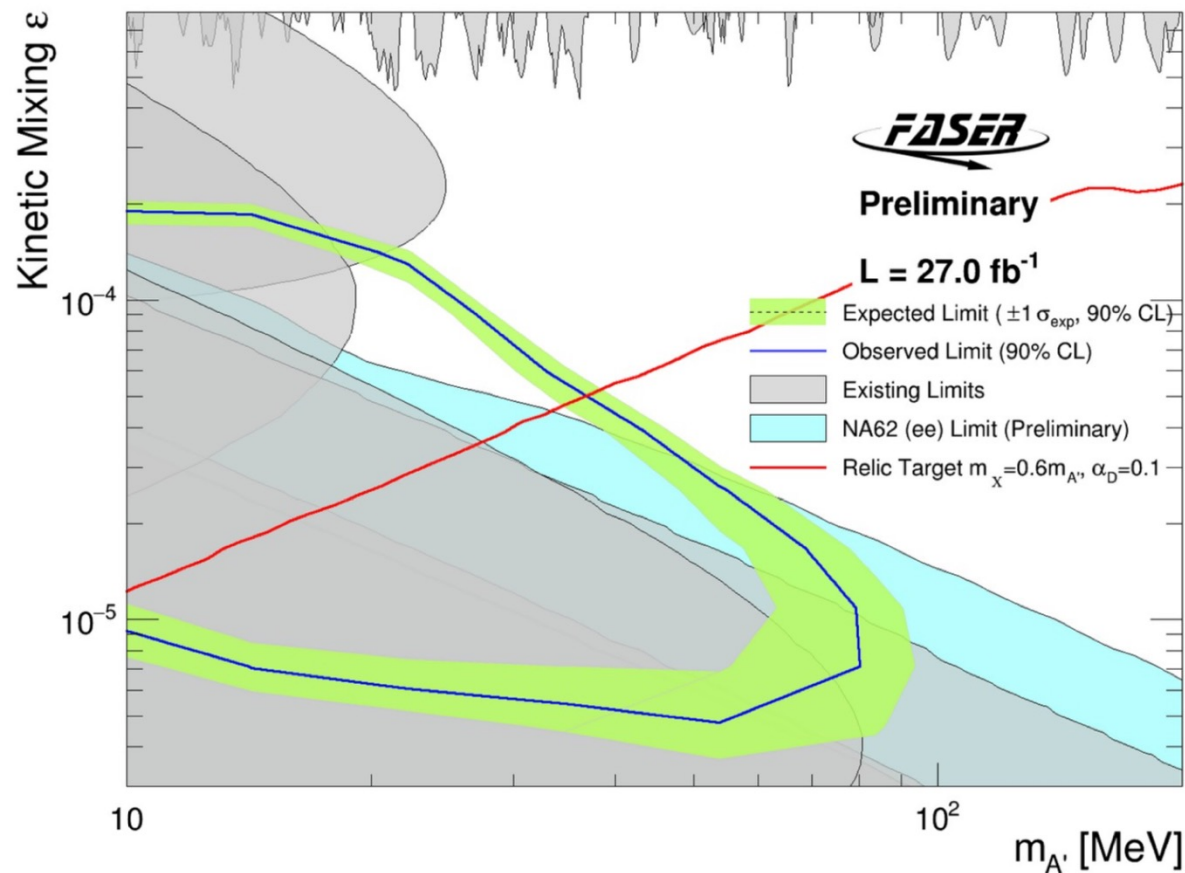

Source	Systematic Uncertainty	Typical Effect on Signal Yield
Theory, Statistics and Luminosity		
A' cross section	$\frac{0.15 + (E_{A'}/4 \text{ TeV})^3}{1 + (E_{A'}/4 \text{ TeV})^3}$	15-45%

IMPACT OF VIBRATION TO HL-LHC PERFORMANCE DURING THE FPF FACILITY CONSTRUCTION*

D. Gamba¹, H. Bartosik, M. Guinchard, K. Pál, J. Wenninger, K. Widuch
 CERN, Geneva, Switzerland

Abstract

The Forward Physics Facility (FPF) is a proposed experimental facility to be installed several hundred meters downstream from the ATLAS interaction point to intercept long-lived particles and neutrinos produced along the beam collision axis and which are therefore outside of the acceptance of the ATLAS detector. The construction of this facility, and in particular the excavation of the associated shaft and cavern, could take place in parallel to beam operation in the CERN accelerator complex. It is therefore important to verify that the ground motion caused by these works does not perturb the standard operation of the SPS and LHC. In this work, the sensitivity to vibration and misalignments of the SPS and LHC rings in the vicinity of the affected area will be presented, together with the expected perturbations on beam operation following the experience gathered during the construction of the HL-LHC infrastructure around the ATLAS experiment.

more recently in preparation of HL-LHC civil engineering works during LHC operation [6–8]. Also for the proposed FPF facility, a series of feasibility studies have been launched, and the present status is summarised in Ref. [9]. In this paper, we aim at progressing on the following aspects:

- Provide an analysis of SPS and HL-LHC sensitivity to quadrupole displacements;
- Estimate the vibration levels that could impact HL-LHC luminosity production;
- Estimate the impact of possible local deformation of LHC and SPS tunnels on the operability of those accelerators without the need for realignment.

Experience shows that both vibration and tunnel deformation primarily affect the vertical plane, therefore we will concentrate our attention on this plane, even though from a beam optics point of view both planes will be approximately equally sensitive in both machines.

INTRODUCTION

The installation of FPF [1] requires the excavation of a 65 meter-long and 9.65 meter-wide cavern at about 620 meters in the line of sight of the LHC Interaction Point 1 (IP1). This cavern will be about 10 meters away from the LHC tunnel and will be accessible by a 90-meter-deep access shaft, which will also need to be excavated. A layout of the site with the relevant distances from the nearby LHC and SPS tunnels is shown in Fig. 1.

OPTICS SENSITIVITY

In linear optics, the closed orbit distortion Δx_s at a location s caused by a static kick θ_{s_0} generated at a location s_0 , is given by:

$$\Delta x_s = \frac{\theta_{s_0} \sqrt{\beta_s \beta_{s_0}}}{2 \sin(\pi Q_x)} \cos(\pi Q_x - 2\pi[\phi_{s_0, s}]), \quad (1)$$

where $\phi_{s_0, s} = \phi_s - \phi_{s_0}$ is the phase advance between observation and kick locations. For many kick sources (j) the total closed orbit variation at a generic downstream location s is obtained as the sum over all kicks, and, developing the cos term in Eq. (1), and using exponential notation, one can easily demonstrate that:

$$\frac{\Delta x_s}{\sqrt{\beta_s}} \leq \frac{1}{2 \sin(\pi Q_x)} \left| \sum_j \theta_{s_0, j} \sqrt{\beta_{s_0, j}} \exp(j 2\pi \phi_{s_0, s}) \right|, \quad (2)$$

or more conveniently written as:

$$\frac{\Delta x_s}{\sqrt{\epsilon_G \beta_s}} \leq \left| \sum_j \theta_{s_0, j} A_j \exp(j 2\pi \phi_{s_0, s}) \right|, \quad (3)$$

where A_j is a function that can be computed for a given optics, and the geometric emittance normalisation $1/\sqrt{\epsilon_G}$ is used to conveniently express the displacements in terms of the local beam size, which can be a metric for comparing different optics or machines, even if this does not take into account the available or required aperture (which is not considered here). The phase advance $\phi_{s_0, s}$ in Eq. (3) is defined with respect to an arbitrary location.

Neutron Dose at FPF

F. Cerutti, M. Sabate-Gilarte
SY-STI

FLUKA simulations used to look at neutron dose level in FPF (relevant for radiation to electronics and radiation damage).

Neutron dose $\sim 0.2 \text{ Hz/cm}^2$ at $L=5e34$.

Also shown:

1MeV n equiv fluence (relevant for silicon radiation damage)

High energy hadron fluence (relevant for SEU in electronics)

Both shown for 1 year at $L=7.5e34$ (ultimate HL-LHC lumi)

HEH fluence $< 3e16 \text{ cm}^{-2} \text{ y}^{-1}$ (LHC threshold for radiation for electronics).

Si 1 MeV n equivalent fluence
[cm^{-2} for 360 fb^{-1}]

High energy hadron equivalent fluence
[cm^{-2} for 360 fb^{-1}]

- Direct contribution from muons from IP1/LSS1 can limit the accessibility to the cavern during LHC operation
 - > 6 mSv/year may be achieved locally;
- Classification of the cavern as Simple Controlled/Supervised Radiation Area
 - low occupancy, i.e. < 20% working time seems possible;
- Access to the cavern during LHC beam operation will be limited to Radiation Workers
 - Also relevant for external personnel involved in the excavation (of the cavern and the lower part of the shaft) if done during beam operation
- No permanent control rooms are foreseen underground.
 - During installation and commissioning there may be people in the cavern for an extended period: this time shall be quantified to finalize the RP risk assessment;
- Final study to be done considering a full integration model, i.e. including detectors, service equipment, ...

3D EXISTING

3D NEW

Currently proposed FPF experiments

At the moment there are 5 proposed experiments to be situated in the FPF.
With different capabilities and covering different rapidity regions:

- FLArE
 - $\mathcal{O}(10\text{tn})$ LAr TPC detector
 - DM scattering
 - Neutrino physics (ν_μ/ν_e , capability for ν_τ under study)
 - Full view of neutrino interaction event
- FASERv2
 - $\mathcal{O}(20\text{tn})$ emulsion/tungsten detector (FASERv x20)
 - Mostly for tau neutrino physics
 - Interfaced to FASER2 spectrometer for muon charge ID ($\nu_\tau/\bar{\nu}_\tau$ separation)
- AdvSND
 - Neutrino detector slightly off-axis
 - Provides complementary sensitivity for PDFs from covering different rapidity to FASERv2
- FASER2
 - Detector for observing decays of light dark-sector particles
 - Similar to scaled up version of FASER (1m radius vs 0.1m)
 - Increases sensitivity to particles produced in heavy flavour decay
 - Larger size requires change in detector and magnet technology: Superconducting magnet
- FORMOSA
 - Milicharged particle detector
 - Scintillator based, similar to current miliQan experiment

Jamie Boyd

FLArE

FASERv2

FORMOSA

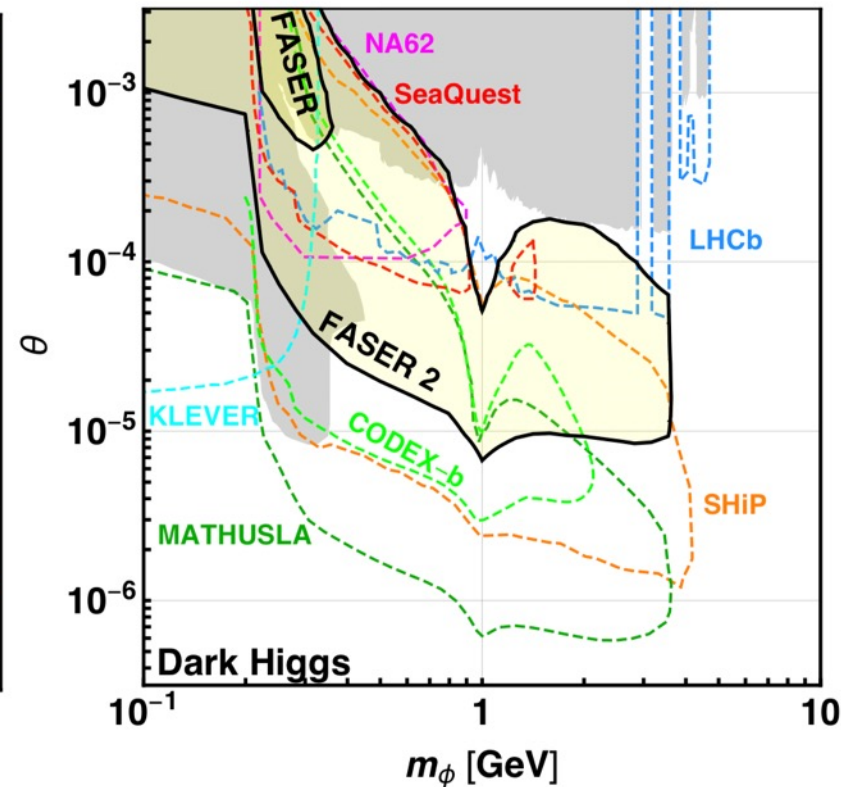

FASER2

FASER/FASER 2 physics reach for various models

Dark photon

Dark higgs

Sterile neutrino

Improvement of the TeV neutrino study

$O(10^3-10^4)$ of Tau neutrino, allowing detailed measurement of final state

- The first Discrimination tau neutrino / anti-tau neutrino
- New information of proton PDF (gluon, charm, strange ..)

Preliminary (optimistic) schedule of HL-LHC

Pure CE works (including connection to LHC)

Installation and commissioning of the experiments

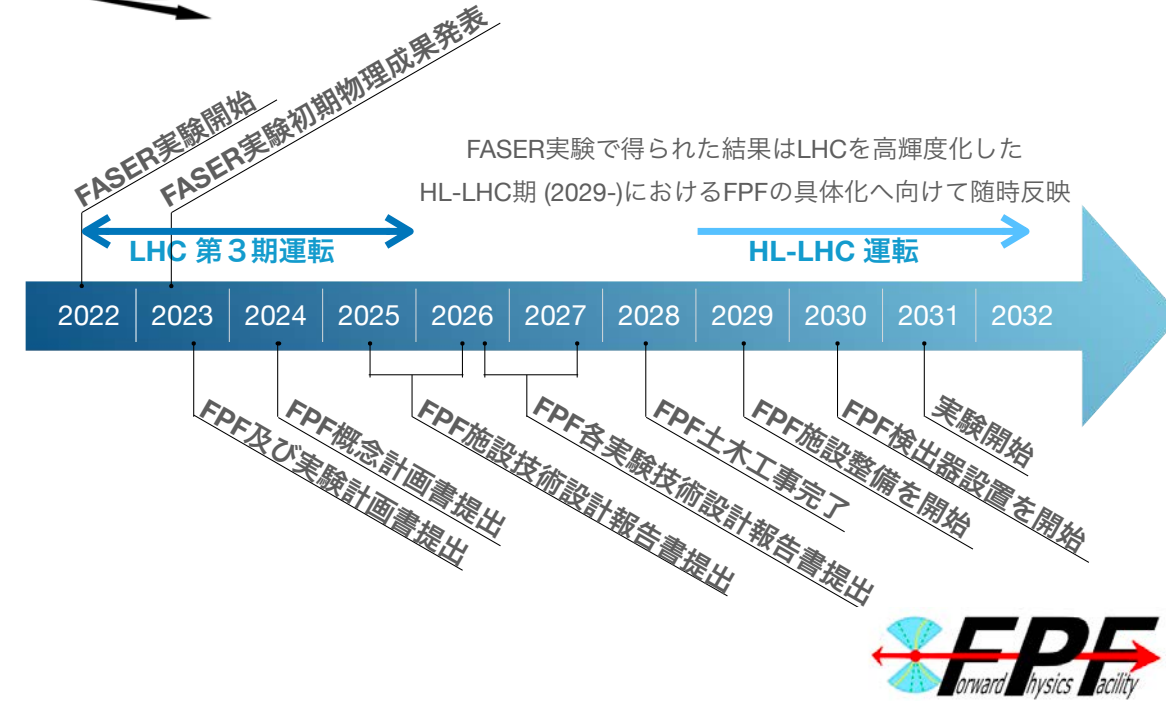

Installation of services (CERN technical teams, busy during LS3)

Such a schedule would:

- Allow physics data taking for most of the luminosity of the HL-LHC
- Not overload CERN technical teams during LS3
- Design of facility would allow different experiments to come online at different times

Requirements:

- Can access the facility during LHC operations (RP study ongoing)
- Can complete CE works before the end of LS3

- We -the steering committee- have started some higher level discussions
- PBC can/will sign off after:
 - We conclude on some some outstanding issues on isses on the facility update the document CERN-PBC-Notes-2023-002
 - “Demonstrate the experiments can well mutually fit in the available space”
- This would open the door to sent a LOI to the LHCC for review(*) by end 2023/or beginning 2024
- The LHCC wil then determine the next steps

(*) ...if no veto from CERN top management...

WG8 Advanced SND Giovanni De Lellis (Napoli)

WG9 FORMOSA Matthew Citron (UC Davis), Chris Hill (Ohio State)

Conclusion

FASER is a new forward experiment at the LHC in the unused tunnel, TI12 for:

- discovery of a light weakly-coupled particle in MeV-GeV range
 - Spectrometer (Tracker and magnets), scintillators and calorimeter installed in March 2021
 - preshower scintillator will be replaced by silicon pixel detector at the end of 2024
- probe all flavors of neutrinos at the TeV-energy frontier
 - Emulsion/Tungsten detector, veto scintillator and interface tracker installed in March 2022
 - Emulsion/Tungsten detector replaced every Technical Shutdown (~3 times in one year)

Successful data taking from the beginning of LHC Run3 in 2022

- the first search of MeV-GeV weakly-interacting particle -- no discovery but more will come soon!
- the first observation of TeV neutrino produced by colliders

Towards HL-LHC, Forward Physics Facility is proposed to host several experiments

- Workshop organized every half year for intensive discussion toward conceptual design
 - The next one (FPF6) will come in June 8-9 <https://indico.cern.ch/event/1275380>
 - Please register and join !!

FASER is supported by:

In addition, FASERv is supported by:

And would additionally like to thank

- LHC for the excellent performance in 2022
- ATLAS for providing luminosity information
- ATLAS for use of ATHENA s/w framework
- ATLAS SCT for spare tracker modules
- LHCb for spare ECAL modules
- CERN FLUKA team for background sim
- CERN PBC and technical infrastructure groups for excellent support during design construction and installation

FPF studies supported by:
