Introduction to Transverse Beam Dynamics

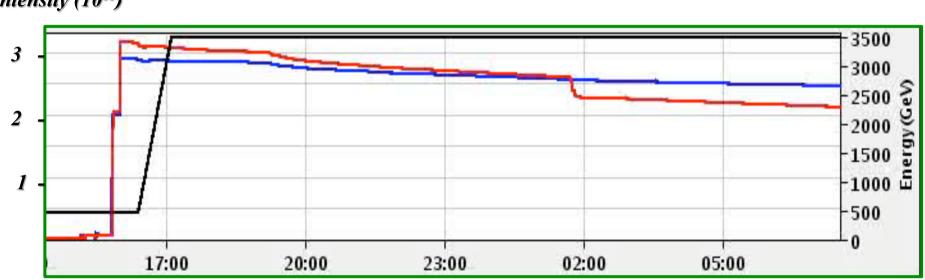

Bernhard Holzer, CERN-LHC

I.) Magnetic Fields and Particle Trajectories

Luminosity Run of a typical storage ring:

LHC Storage Ring: Protons accelerated and stored for 12 hours distance of particles travelling at about $v \approx c$ $L = 10^{10} - 10^{11} \text{ km}$

... several times Sun - Pluto and back

intensity (10¹¹)

- → guide the particles on a well defined orbit ("design orbit")
- → focus the particles to keep each single particle trajectory within the vacuum chamber of the storage ring, i.e. close to the design orbit.

Transverse Beam Dynamics:

0.) Introduction and Basic Ideas

" ... in the end and after all it should be a kind of circular machine"

 \rightarrow need transverse deflecting force

Lorentz force
$$F = q (\vec{E} + \vec{v} \times \vec{B})$$

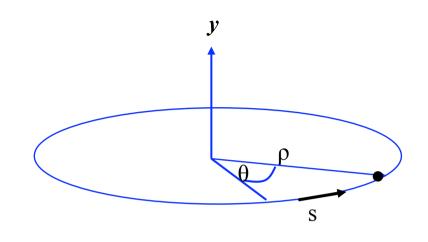

typical velocity in high energy machines: $v \approx c \approx 3 * 10^8 \frac{m}{s}$

old greek dictum of wisdom:

if you are clever, you use magnetic fields in an accelerator wherever it is possible.

But remember: magn. fields act allways perpendicular to the velocity of the particle \rightarrow only bending forces, \rightarrow no "beam acceleration"

The ideal circular orbit

circular coordinate system

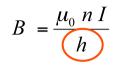

condition for circular orbit:

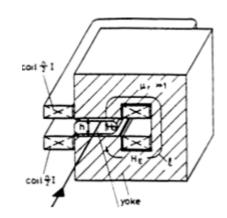

Lorentz force $F_L = e v B$ centrifugal force $F_{centr} = \frac{\gamma m_0 v^2}{\rho}$ $\frac{\gamma m_0 v}{\rho} = e v B$ $B \rho = "beam rigidity"$

1.) The Magnetic Guide Field

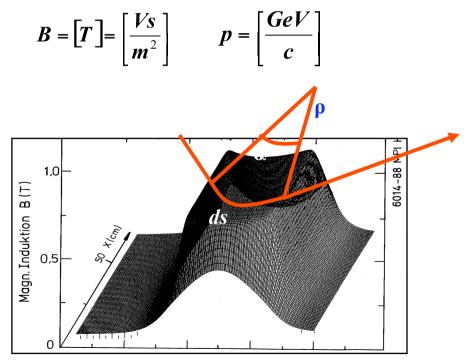

Dipole Magnets:

define the ideal orbit homogeneous field created by two flat pole shoes

convenient units:

field map of a storage ring dipole magnet

Example LHC:

$$B = 8.3T$$
$$p = 7000 \frac{GeV}{c}$$

Normalise magnetic field to momentum:

$$\frac{p}{e} = B \rho \qquad \longrightarrow \qquad \frac{1}{\rho} = \frac{e B}{p}$$

The Magnetic Guide Field

$$\frac{1}{\rho} = e \frac{\frac{8.3 \, Vs}{m^2}}{7000*10^9 \, eV/c} = \frac{8.3 \, s \, 3*10^8 \, m/s}{7000*10^9 \, m^2}$$
$$\frac{1}{\rho} = 0.3 \frac{8.3}{7000} \frac{1}{m}$$

$$\rho = 2.53 \text{ km} \longrightarrow 2\pi\rho = 17.6 \text{ km}$$

 $\approx 66\%$

$$\boldsymbol{B} \approx 1 \dots 8 \ \boldsymbol{T}$$

rule of thumb:

$$\frac{1}{\rho} \approx 0.3 \frac{B[T]}{p[GeV/c]}$$

"normalised bending strength"

2.) Quadrupole Magnets:

focusing forces to keep trajectories in vicinity of the ideal orbit required: linear increasing Lorentz force linear increasing magnetic field

normalised quadrupole field:

gradient of a quadrupole magnet:

$$g = \frac{2\mu_0 nI}{r^2}$$

e

$$k = \frac{\xi}{p}$$

simple rule:

$$c = 0.3 \frac{g(T/m)}{p(GeV/c)}$$

$$B_{y} = g x \qquad B_{x} = g y$$

LHC main quadrupole magnet

 $g \approx 25 \dots 220 T / m$

$$\vec{\nabla} \times \vec{B} = \vec{\nabla} + \frac{\partial \vec{E}}{\partial t} = 0 \qquad \Rightarrow \qquad \frac{\partial B_y}{\partial x} = \frac{\partial B_x}{\partial y}$$

3.) The equation of motion:

Linear approximation:

* ideal particle \rightarrow design orbit

* any other particle \rightarrow coordinates x, y small quantities x,y << ρ

> → magnetic guide field: only linear terms in x & y of B have to be taken into account

Taylor Expansion of the B field:

 $\boldsymbol{B}_{y}(\boldsymbol{x}) = \boldsymbol{B}_{y0} + \frac{d\boldsymbol{B}_{y}}{d\boldsymbol{x}}\boldsymbol{x} + \frac{1}{2!}\frac{d^{2}\boldsymbol{B}_{y}}{d\boldsymbol{x}^{2}}\boldsymbol{x}^{2} + \frac{1}{3!}\frac{\boldsymbol{e}\boldsymbol{g}^{\prime\prime}}{d\boldsymbol{x}^{3}} + \dots \qquad \text{normalise to momentum}$

$$\frac{B(x)}{p/e} = \frac{B_0}{B_0\rho} + \frac{g^*x}{p/e} + \frac{1}{2!}\frac{eg'}{p/e} + \frac{1}{3!}\frac{eg''}{p/e} + \dots$$

The Equation of Motion:

$$\frac{B(x)}{p/e} = \frac{1}{\rho} + k x + \frac{1}{2!}m x^2 + \frac{1}{3!}m x^3 + \dots$$

only terms linear in x, y taken into account dipole fields quadrupole fields

Separate Function Machines:

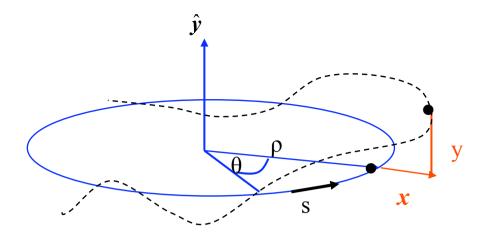

Split the magnets and optimise them according to their job:

bending, focusing etc

Example: heavy ion storage ring TSR

Equation of Motion:

Consider local segment of a particle trajectory ... and remember the old days: (Goldstein page 27)

radial acceleration:

$$a_r = \frac{d^2 \rho}{dt^2} - \rho \left(\frac{d\theta}{dt}\right)^2$$

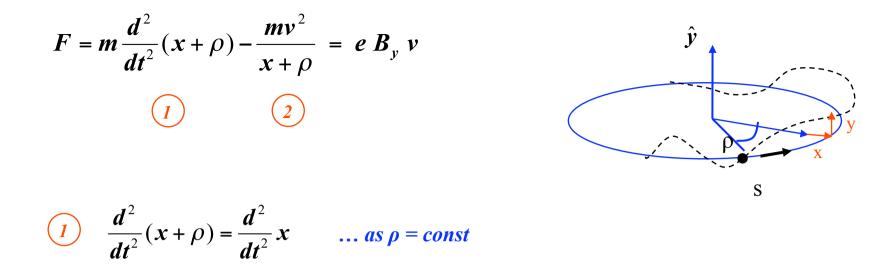

Ideal orbit: $\rho = const, \quad \frac{d\rho}{dt} = 0$

Force:
$$F = m\rho \left(\frac{d\theta}{dt}\right)^2 = m\rho\omega^2$$

 $F = mv^2 / \rho$

general trajectory: $\rho \rightarrow \rho + x$

$$F = m \frac{d^2}{dt^2} (x + \rho) - \frac{mv^2}{x + \rho} = e B_y v$$

remember:
$$x \approx mm$$
, $\rho \approx m \dots \rightarrow$ develop for small x

$$\frac{1}{x+\rho} \approx \frac{1}{\rho} (1-\frac{x}{\rho})$$

2

Taylor Expansion

$$f(x) = f(x_0) + \frac{(x - x_0)}{1!} f'(x_0) + \frac{(x - x_0)^2}{2!} f''(x_0) + \dots$$

$$m\frac{d^2x}{dt^2} - \frac{mv^2}{\rho}(1-\frac{x}{\rho}) = eB_y v$$

guide field in linear approx.

$$B_{y} = B_{0} + x \frac{\partial B_{y}}{\partial x} \qquad m \frac{d^{2}x}{dt^{2}} - \frac{mv^{2}}{\rho} (1 - \frac{x}{\rho}) = ev \left\{ B_{0} + x \frac{\partial B_{y}}{\partial x} \right\} \qquad : m$$
$$\frac{d^{2}x}{dt^{2}} - \frac{v^{2}}{\rho} (1 - \frac{x}{\rho}) = \frac{ev B_{0}}{m} + \frac{ev x g}{m}$$

independent variable: $t \rightarrow s$

$$\frac{dx}{dt} = \frac{dx}{ds} \frac{ds}{dt}$$

$$\frac{d^2x}{dt^2} = \frac{d}{dt} \left(\frac{dx}{ds} \frac{ds}{dt} \right) = \frac{d}{ds} \left(\frac{dx}{ds} \frac{ds}{dt} \right) \frac{ds}{dt}$$

$$\frac{d^2x}{dt^2} = x'' v^2 + \frac{dx}{ds} \frac{dv}{ds} v$$

$$x'' v^2 - \frac{v^2}{\rho} (1 - \frac{x}{\rho}) = \frac{e v B_0}{m} + \frac{e v x g}{m}$$

$$: v^2$$

$$x'' - \frac{1}{\rho} (1 - \frac{x}{\rho}) = \frac{e B_0}{mv} + \frac{e x g}{mv}$$
$$x'' - \frac{1}{\rho} + \frac{x}{\rho^2} = \frac{B_0}{p/e} + \frac{x g}{p/e}$$
$$x'' - \frac{1}{\rho} + \frac{x}{\rho^2} = -\frac{1}{\rho} + k x$$

$$\boldsymbol{x}'' + \boldsymbol{x}\left(\frac{1}{\rho^2} - \boldsymbol{k}\right) = 0$$

$$\frac{1}{\rho^2} = 0$$
 no dipoles ... in general ...

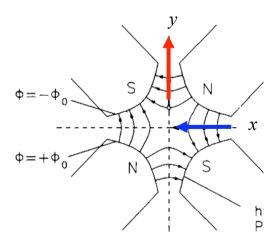

$$k \iff -k$$
 quadrupole field changes sign

$$y'' + k y = 0$$

$$m v = p$$

normalize to momentum of particle

$$\frac{B_0}{p/e} = -\frac{1}{\rho}$$
$$\frac{g}{p/e} = k$$

Remarks:

*
$$x'' + (\frac{1}{\rho^2} - k) \cdot x = 0$$

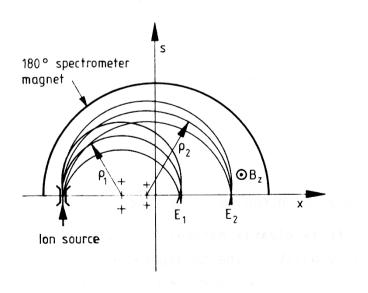

... there seems to be a focusing even without a quadrupole gradient

"weak focusing of dipole magnets"

$$k = 0 \implies x'' = -\frac{1}{\rho^2} x$$

even without quadrupoles there is a retriving force (i.e. focusing) in the bending plane of the dipole magnets

... in large machines it is weak. (!)

Mass spectrometer: particles are separated according to their energy and focused due to the $1/\rho$ effect of the dipole

***** Hard Edge Model:

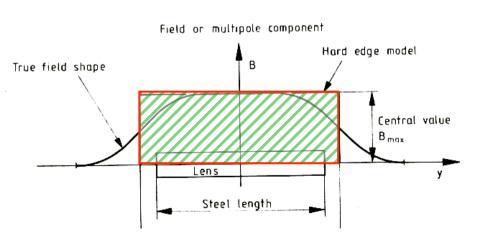

$$\mathbf{x}'' + \left\{\frac{1}{\rho^2} - \mathbf{k}\right\} \mathbf{x} = 0 \qquad \cdot$$
$$\mathbf{x}''(\mathbf{s}) + \left\{\frac{1}{\rho^2(\mathbf{s})} - \mathbf{k}(\mathbf{s})\right\} \mathbf{x}(\mathbf{s}) = 0$$

... this equation is not correct !!!

bending and focusing fields ... are functions of the independent variable "s"

Inside a magnet we assume constant focusing properties !

$$\frac{1}{\rho} = const$$
 $k = const$

$$\boldsymbol{B} \boldsymbol{l}_{eff} = \int_{0}^{l_{mag}} \boldsymbol{B} \boldsymbol{ds}$$

4.) Solution of Trajectory Equations

Define ... hor. plane: $K = 1/\rho^2 - k$... vert. Plane: K = k

$$\boldsymbol{x}'' + \boldsymbol{K} \boldsymbol{x} = \boldsymbol{0}$$

Differential Equation of harmonic oscillator ... with spring constant K

Ansatz:
$$x(s) = a_1 \cdot \cos(\omega s) + a_2 \cdot \sin(\omega s)$$

general solution: linear combination of two independent solutions

$$x'(s) = -a_1 \omega \sin(\omega s) + a_2 \omega \cos(\omega s)$$
$$x''(s) = -a_1 \omega^2 \cos(\omega s) - a_2 \omega^2 \sin(\omega s) = -\omega^2 x(s) \longrightarrow \omega = \sqrt{K}$$

general solution:

$$x(s) = a_1 \cos(\sqrt{K}s) + a_2 \sin(\sqrt{K}s)$$

determine a_1 , a_2 by boundary conditions:

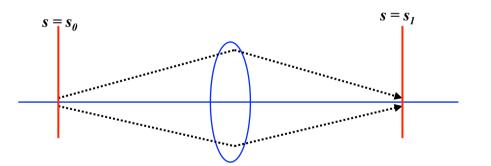

$$s = 0 \qquad \longrightarrow \qquad \begin{cases} x(0) = x_0 &, a_1 = x_0 \\ x'(0) = x'_0 &, a_2 = \frac{x'_0}{\sqrt{K}} \end{cases}$$

Hor. Focusing Quadrupole K > 0:

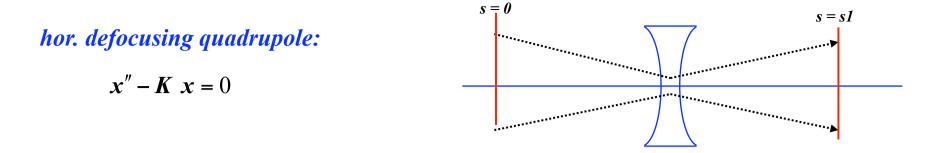

$$x(s) = x_0 \cdot \cos(\sqrt{|K|}s) + x'_0 \cdot \frac{1}{\sqrt{|K|}} \sin(\sqrt{|K|}s)$$
$$x'(s) = -x_0 \cdot \sqrt{|K|} \cdot \sin(\sqrt{|K|}s) + x'_0 \cdot \cos(\sqrt{|K|}s)$$

For convenience expressed in matrix formalism:

$$\binom{x}{x'}_{s1} = M_{foc} * \binom{x}{x'}_{s0}$$

$$M_{foc} = \begin{pmatrix} \cos(\sqrt{|K|}s) & \frac{1}{\sqrt{|K|}}\sin(\sqrt{|K|}s) \\ -\sqrt{|K|}\sin(\sqrt{|K|}s) & \cos(\sqrt{|K|}s) \end{pmatrix}_0$$

Remember from school:

$$f(s) = \cosh(s)$$
, $f'(s) = \sinh(s)$

Ansatz: $x(s) = a_1 \cdot \cosh(\omega s) + a_2 \cdot \sinh(\omega s)$

$$M_{def oc} = \begin{pmatrix} \cosh \sqrt{|K|}l & \frac{1}{\sqrt{|K|}} \sinh \sqrt{|K|}l \\ \sqrt{|K|} \sinh \sqrt{|K|}l & \cosh \sqrt{|K|}l \end{pmatrix}$$

drift space:

K = 0

$$M_{drif t} = \begin{pmatrix} 1 & l \\ 0 & 1 \end{pmatrix}$$

! with the assumptions made, the motion in the horizontal and vertical planes are independent "… the particle motion in x & y is uncoupled"

Thin Lens Approximation:

matrix of a quadrupole lens
$$M = \begin{pmatrix} \cos \sqrt{|k|}l & \frac{1}{\sqrt{|k|}} \sin \sqrt{|k|}l \\ -\sqrt{|k|} \sin \sqrt{|k|}l & \cos \sqrt{|k|}l \end{pmatrix}$$

in many practical cases we have the situation:

 $f = \frac{1}{kl_q} >> l_q$... focal length of the lens is much bigger than the length of the magnet

limes:
$$l_q \rightarrow 0$$
 while keeping $k l_q = const$

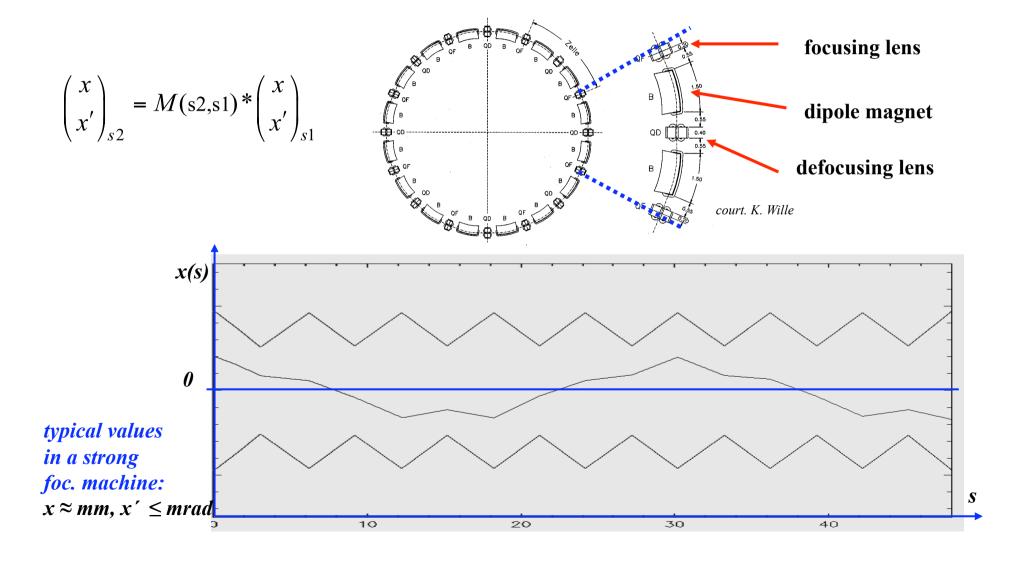

$$M_x = \begin{pmatrix} 1 & 0 \\ \frac{1}{f} & 1 \end{pmatrix} \qquad \qquad M_z = \begin{pmatrix} 1 & 0 \\ \frac{-1}{f} & 1 \end{pmatrix}$$

... useful for fast (and in large machines still quite accurate) "back on the envelope calculations" ... and for the guided studies !

Transformation through a system of lattice elements

combine the single element solutions by multiplication of the matrices

$$M_{total} = M_{QF} * M_D * M_{QD} * M_{Bend} * M_{D*\dots}$$

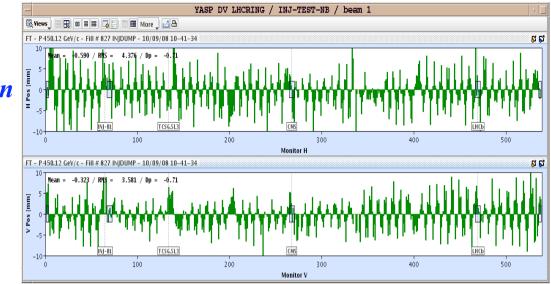

5.) Orbit & Tune:

Tune: number of oscillations per turn

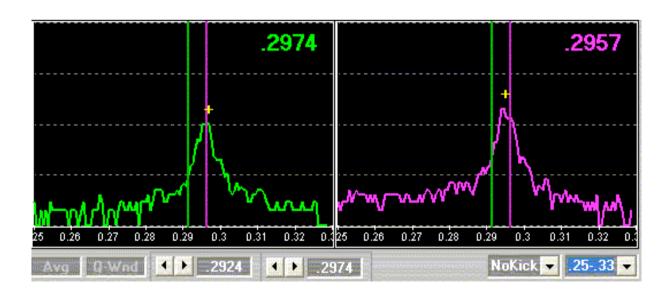

64.31 59.32

Relevant for beam stability: non integer part

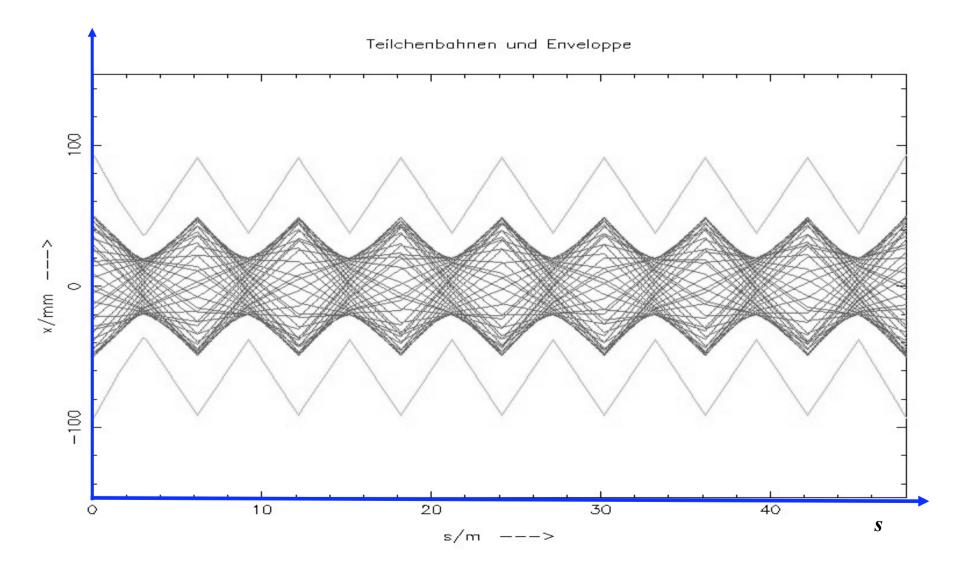

LHC revolution frequency: 11.3 kHz

0.31*11.3 kHz = 3.5 kHz

Question: what will happen, if the particle performs a second turn ?

... or a third one or ... 10¹⁰ turns

Astronomer Hill:

differential equation for motions with periodic focusing properties "Hill's equation"

Example: particle motion with periodic coefficient

equation of motion:

$$x''(s) - k(s)x(s) = 0$$

restoring force \neq const, k(s) = depending on the position s k(s+L) = k(s), periodic function we expect a kind of quasi harmonic oscillation: amplitude & phase will depend on the position s in the ring.

6.) The Beta Function

General solution of Hill's equation:

(i) $x(s) = \sqrt{\varepsilon} \sqrt{\beta(s)} \cdot \cos(\psi(s) + \phi)$

 ε , Φ = integration constants determined by initial conditions $\beta(s)$ periodic function given by focusing properties of the lattice \leftrightarrow quadrupoles

 $\beta(s+L) = \beta(s)$

Inserting (i) into the equation of motion ...

$$\psi(s) = \int_0^s \frac{ds}{\beta(s)}$$

 $\Psi(s) = ,, phase advance"$ of the oscillation between point ,, 0" and ,, s" in the lattice. For one complete revolution: number of oscillations per turn ,, Tune"

$$Q_y = \frac{1}{2\pi} \oint \frac{ds}{\beta(s)}$$

7.) Beam Emittance and Phase Space Ellipse

general solution of
Hill equation
$$\begin{cases}
(1) \quad x(s) = \sqrt{\varepsilon} \sqrt{\beta(s)} \cos(\psi(s) + \phi) \\
(2) \quad x'(s) = -\frac{\sqrt{\varepsilon}}{\sqrt{\beta(s)}} \left\{ \alpha(s) \cos(\psi(s) + \phi) + \sin(\psi(s) + \phi) \right\}
\end{cases}$$

from (1) we get

$$\cos(\psi(s) + \phi) = \frac{x(s)}{\sqrt{\varepsilon} \sqrt{\beta(s)}}$$

$$\alpha(s) = \frac{-1}{2}\beta'(s)$$
$$\gamma(s) = \frac{1 + \alpha(s)^2}{\beta(s)}$$

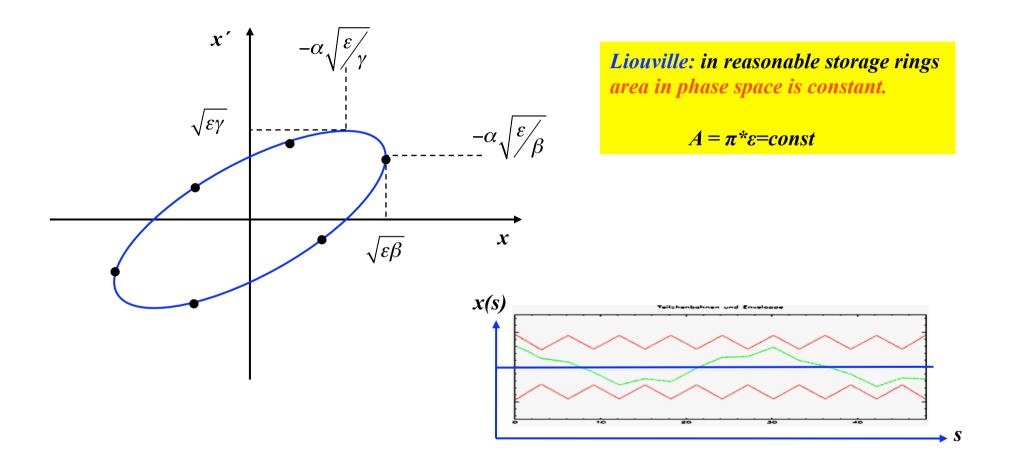

Insert into (2) and solve for ε

$$\varepsilon = \gamma(s) x^2(s) + 2\alpha(s)x(s)x'(s) + \beta(s) x'^2(s)$$

* ε is a constant of the motion ... it is independent of "s" * parametric representation of an ellipse in the x x' space * shape and orientation of ellipse are given by α , β , γ

Beam Emittance and Phase Space Ellipse

$$\varepsilon = \gamma(s) x^2(s) + 2\alpha(s)x(s)x'(s) + \beta(s) x'^2(s)$$

ε beam emittance = woozilycity of the particle ensemble, intrinsic beam parameter, cannot be changed by the foc. properties. Scientifiquely speaking: area covered in transverse x, x' phase space ... and it is constant !!!

Phase Space Ellipse

particel trajectory:
$$x(s) = \sqrt{\varepsilon} \sqrt{\beta(s)} \cos \{\psi(s) + \phi\}$$

max. Amplitude: $\hat{x}(s) = \sqrt{\varepsilon\beta} \longrightarrow x'$ at that position ...?

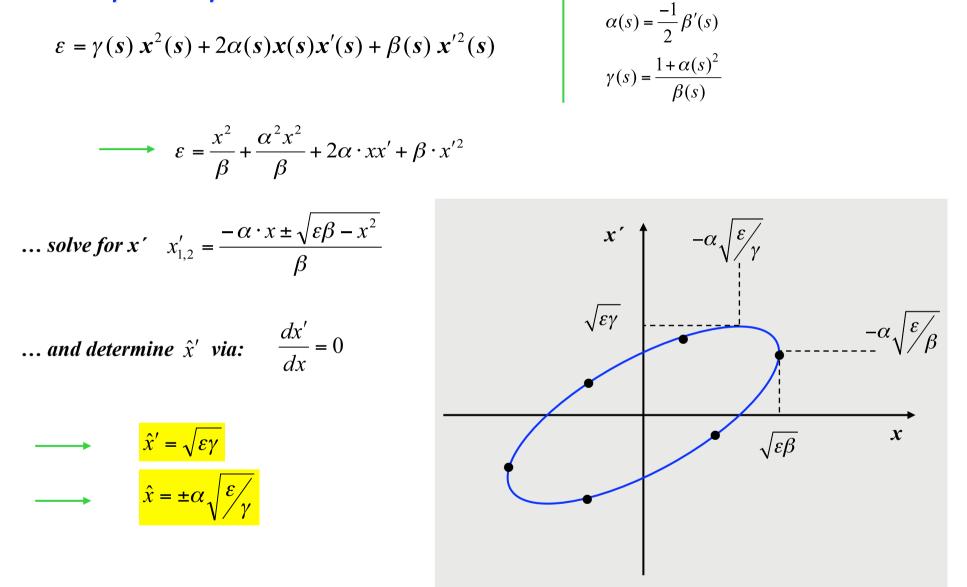

... put
$$\hat{x}(s)$$
 into $\varepsilon = \gamma(s) x^2(s) + 2\alpha(s)x(s)x'(s) + \beta(s) x'^2(s)$ and solve for x'
 $\varepsilon = \gamma \cdot \varepsilon \beta + 2\alpha \sqrt{\varepsilon \beta} \cdot x' + \beta x'^2$
 $\longrightarrow x' = -\alpha \cdot \sqrt{\varepsilon / \beta}$

* A high β-function means a large beam size and a small beam divergence. ... et vice versa !!!

* In the middle of a quadrupole
$$\beta = maximum$$
,
 $\alpha = zero$
 $x' = 0$
... and the ellipse is flat

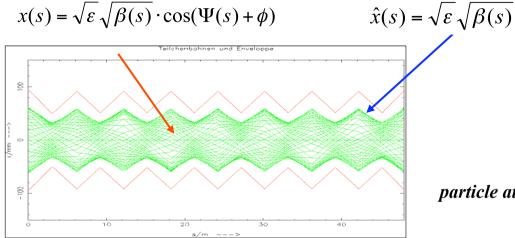

!

Phase Space Ellipse

shape and orientation of the phase space ellipse depend on the Twiss parameters $\beta \alpha \gamma$

Emittance of the Particle Ensemble:

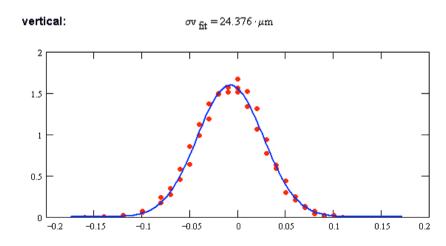

Gauß
Particle Distribution:

 $\rho(\mathbf{x}) = \frac{N \cdot \mathbf{e}}{\sqrt{2\pi}\sigma_{\mathbf{x}}} \cdot \mathbf{e}^{-\frac{1}{2}\frac{\mathbf{x}^2}{\sigma_{\mathbf{x}}^2}}$

particle at distance 1 σ from centre \leftrightarrow 68.3 % of all beam particles

LHC: $\sigma = \sqrt{\varepsilon * \beta} = \sqrt{5*10^{-10} m * 180 m} = 0.3 mm$

aperture requirements: $r_0 = 10 * \sigma$

8.) Transfer Matrix M ... yes we had the topic already

general solution
of Hill's equation
$$\begin{cases} x(s) = \sqrt{\varepsilon} \sqrt{\beta(s)} \cos \left\{ \psi(s) + \phi \right\} \\ x'(s) = \frac{-\sqrt{\varepsilon}}{\sqrt{\beta(s)}} \left[\alpha(s) \cos \left\{ \psi(s) + \phi \right\} + \sin \left\{ \psi(s) + \phi \right\} \right] \end{cases}$$

remember the trigonometrical gymnastics: $sin(a + b) = \dots etc$

$$x(s) = \sqrt{\varepsilon} \sqrt{\beta_s} \left(\cos\psi_s \cos\phi - \sin\psi_s \sin\phi \right)$$
$$x'(s) = \frac{-\sqrt{\varepsilon}}{\sqrt{\beta_s}} \left[\alpha_s \cos\psi_s \cos\phi - \alpha_s \sin\psi_s \sin\phi + \sin\psi_s \cos\phi + \cos\psi_s \sin\phi \right]$$

starting at point $s(0) = s_0$, where we put $\Psi(0) = 0$

$$\cos\phi = \frac{x_0}{\sqrt{\varepsilon\beta_0}} ,$$

$$\sin\phi = -\frac{1}{\sqrt{\varepsilon}} (x'_0 \sqrt{\beta_0} + \frac{\alpha_0 x_0}{\sqrt{\beta_0}})$$

inserting above ...

$$x(s) = \sqrt{\frac{\beta_s}{\beta_0}} \left\{ \cos\psi_s + \alpha_0 \sin\psi_s \right\} x_0 + \left\{ \sqrt{\beta_s \beta_0} \sin\psi_s \right\} x_0'$$
$$x'(s) = \frac{1}{\sqrt{\beta_s \beta_0}} \left\{ (\alpha_0 - \alpha_s) \cos\psi_s - (1 + \alpha_0 \alpha_s) \sin\psi_s \right\} x_0 + \sqrt{\frac{\beta_0}{\beta_s}} \left\{ \cos\psi_s - \alpha_s \sin\psi_s \right\} x_0'$$

which can be expressed ... for convenience ... in matrix form

$$\begin{pmatrix} x \\ x' \end{pmatrix}_{s} = M \begin{pmatrix} x \\ x' \end{pmatrix}_{0}$$

*

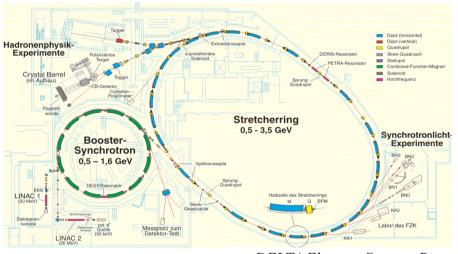

Äquivalenz der Matrizen

$$M = \begin{pmatrix} \sqrt{\frac{\beta_s}{\beta_0}} \left(\cos\psi_s + \alpha_0 \sin\psi_s \right) & \sqrt{\beta_s \beta_0} \sin\psi_s \\ \frac{(\alpha_0 - \alpha_s) \cos\psi_s - (1 + \alpha_0 \alpha_s) \sin\psi_s}{\sqrt{\beta_s \beta_0}} & \sqrt{\frac{\beta_0}{\beta s}} \left(\cos\psi_s - \alpha_s \sin\psi_s \right) \end{pmatrix}$$

* we can calculate the single particle trajectories between two locations in the ring, if we know the α β γ at these positions.
* and nothing but the α β γ at these positions.

*

9.) Periodic Lattices $M = \begin{pmatrix} \sqrt{\frac{\beta_s}{\beta_0}} \left(\cos\psi_s + \alpha_0 \sin\psi_s \right) & \sqrt{\beta_s \beta_0} \sin\psi_s \\ \frac{(\alpha_0 - \alpha_s) \cos\psi_s - (1 + \alpha_0 \alpha_s) \sin\psi_s}{\sqrt{\beta_s \beta_0}} & \sqrt{\frac{\beta_0}{\beta s}} \left(\cos\psi_s - \alpha_s \sin\psi_s \right) \end{pmatrix}$

DELTA Electron Storage Ring

"This rather formidable looking matrix simplifies considerably if we consider one complete revolution ..."

$$\boldsymbol{M}(\boldsymbol{s}) = \begin{pmatrix} \cos \psi_{turn} + \alpha_{s} \sin \psi_{turn} & \beta_{s} \sin \psi_{turn} \\ -\gamma_{s} \sin \psi_{turn} & \cos \psi_{turn} - \alpha_{s} \sin \psi_{turn} \end{pmatrix}$$

$$\psi_{turn} = \int_{s}^{s+L} \frac{ds}{\beta(s)}$$

 $\psi_{turn} = phase advance$ per period

Tune: Phase advance per turn in units of 2π

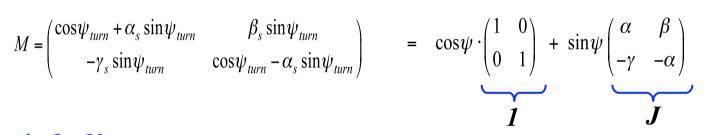

$$Q = \frac{1}{2\pi} \oint \frac{ds}{\beta(s)}$$

Stability Criterion:

Question: what will happen, if we do not make too many mistakes and your particle performs one complete turn ?

Matrix for 1 turn:

Matrix for N turns:

$$M^{N} = (1 \cdot \cos \psi + J \cdot \sin \psi)^{N} = 1 \cdot \cos N\psi + J \cdot \sin N\psi$$

The motion for N turns remains bounded, if the elements of M^N remain bounded

 $\psi = real \quad \Leftrightarrow \quad \left|\cos\psi\right| \le 1 \quad \Leftrightarrow \quad Tr(M) \le 2$

stability criterion proof for the disbelieving collegues !!

Matrix for 1 turn:
$$M = \begin{pmatrix} \cos\psi_{turn} + \alpha_s \sin\psi_{turn} & \beta_s \sin\psi_{turn} \\ -\gamma_s \sin\psi_{turn} & \cos\psi_{turn} - \alpha_s \sin\psi_{turn} \end{pmatrix} = \cos\psi \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \sin\psi \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix}$$
Matrix for 2 turns:

$$M^{2} = (I \cos \psi_{1} + J \sin \psi_{1})(I \cos \psi_{2} + J \sin \psi_{2})$$
$$= I^{2} \cos \psi_{1} \cos \psi_{2} + IJ \cos \psi_{1} \sin \psi_{2} + JI \sin \psi_{1} \cos \psi_{2} + J^{2} \sin \psi_{1} \sin \psi_{2}$$

now ...

$$I^{2} = I$$

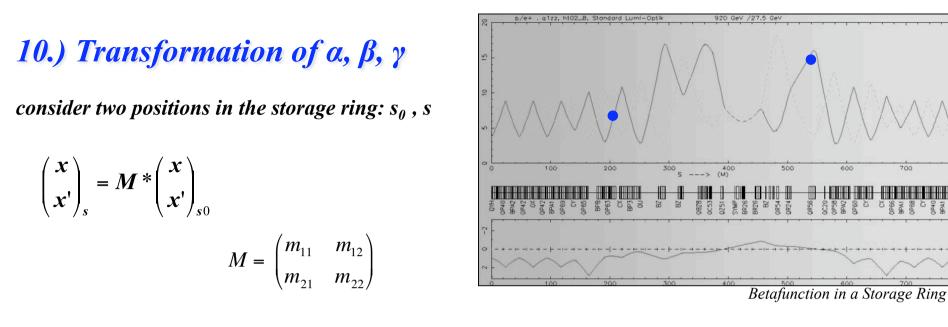

$$I J = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} * \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix} = \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix}$$

$$J I = \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix} * \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix}$$

$$J^{2} = \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix} * \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix} = \begin{pmatrix} \alpha^{2} - \gamma\beta & \alpha\beta - \beta\alpha \\ -\gamma\alpha + \alpha\gamma & \alpha^{2} - \gamma\beta \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = -I$$

 $\boldsymbol{M}^{2} = \boldsymbol{I}\cos(\psi_{1} + \psi_{2}) + \boldsymbol{J}\sin(\psi_{1} + \psi_{2})$

 $\boldsymbol{M}^2 = \boldsymbol{I}\cos(2\psi) + \boldsymbol{J}\sin(2\psi)$

since
$$\varepsilon = const$$
 (Liouville):

$$\varepsilon = \beta_s \mathbf{x}'^2 + 2\alpha_s \mathbf{x}\mathbf{x}' + \gamma_s \mathbf{x}^2$$
$$\varepsilon = \beta_0 \mathbf{x}'^2 + 2\alpha_0 \mathbf{x}_0 \mathbf{x}'_0 + \gamma_0 \mathbf{x}_0^2$$

 \dots remember W = CS'-SC' = 1

$$\begin{pmatrix} \mathbf{x} \\ \mathbf{x'} \end{pmatrix}_{0} = M^{-1} * \begin{pmatrix} \mathbf{x} \\ \mathbf{x'} \end{pmatrix}_{s}$$

$$M^{-1} = \begin{pmatrix} m_{22} & -m_{12} \\ -m_{21} & m_{11} \end{pmatrix}$$

$$x_{0} = m_{22} \mathbf{x} - m_{12} \mathbf{x'}$$

$$x_{0}' = -m_{21} \mathbf{x} + m_{11} \mathbf{x'}$$
... inserting into ε

$$\varepsilon = \beta_0 (m_{11}x' - m_{21}x)^2 + 2\alpha_0 (m_{22}x - m_{12}x')(m_{11}x' - m_{21}x) + \gamma_0 (m_{22}x - m_{12}x')^2$$

sort via x, x'and compare the coefficients to get

The Twiss parameters α , β , γ can be transformed through the lattice via the matrix elements defined above.

$$\beta(s) = m_{11}^2 \beta_0 - 2m_{11}m_{12}\alpha_0 + m_{12}^2 \gamma_0$$

$$\alpha(s) = -m_{11}m_{21}\beta_0 + (m_{12}m_{21} + m_{11}m_{22})\alpha_0 - m_{12}m_{22}\gamma_0$$

$$\gamma(s) = m_{21}^2 \beta_0 - 2m_{21}m_{22}\alpha_0 + m_{22}^2 \gamma_0$$

in matrix notation:

$$\begin{pmatrix} \beta \\ \alpha \\ \gamma \end{pmatrix}_{s2} = \begin{pmatrix} m_{11}^2 & -2m_{11}m_{12} & m_{12}^2 \\ -m_{11}m_{21} & m_{12}m_{21} + m_{22}m_{11} & -m_{12}m_{22} \\ m_{12}^2 & -2m_{22}m_{21} & m_{22}^2 \end{pmatrix} * \begin{pmatrix} \beta \\ \alpha \\ \gamma \end{pmatrix}_{s1}$$

1.) this expression is important

- 2.) given the twiss parameters α , β , γ at any point in the lattice we can transform them and calculate their values at any other point in the ring.
- 3.) the transfer matrix is given by the focusing properties of the lattice elements, the elements of M are just those that we used to calculate single particle trajectories.
- 4.) go back to point 1.)

II.) Acceleration and Momentum Spread

The "not so ideal world "

Remember:

Beam Emittance and Phase Space Ellipse:

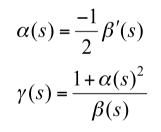

equation of motion: x''(s) - k(s) x(s) = 0

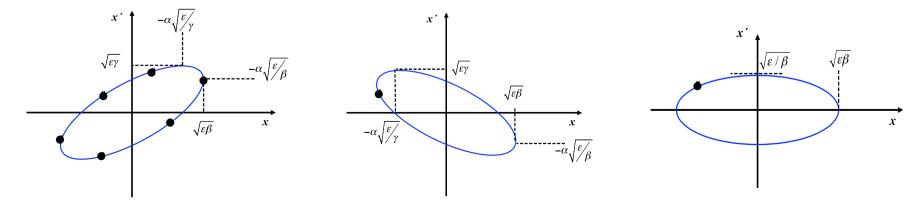

general solution of Hills equation: $x(s) = \sqrt{\varepsilon} \sqrt{\beta(s)} \cos(\psi(s) + \varphi)$

beam size:
$$\sigma = \sqrt{\varepsilon\beta} \approx "mm"$$

$$\varepsilon = \gamma(s) x^{2}(s) + 2\alpha(s)x(s)x'(s) + \beta(s) x'^{2}(s)$$

* ε is a constant of the motion ... it is independent of "s" * parametric representation of an ellipse in the x x' space * shape and orientation of ellipse are given by α , β , γ

11.) Liouville during Acceleration

$$\varepsilon = \gamma(s) x^{2}(s) + 2\alpha(s)x(s)x'(s) + \beta(s) x'^{2}(s)$$

Beam Emittance corresponds to the area covered in the x, x' Phase Space Ellipse

Liouville: Area in phase space is constant.

$$\begin{array}{c|c}
-\alpha \sqrt{\frac{\varepsilon}{\gamma}} \\

\sqrt{\varepsilon\beta} \\
x
\end{array}$$

-

But so sorry ... $\varepsilon \neq const !$

Classical Mechanics:

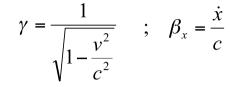

phase space = diagram of the two canonical variables
position & momentum

 $x \qquad p_x$

$$p_j = \frac{\partial L}{\partial \dot{q}_j}$$
; $L = T - V = kin. Energy - pot. Energy$

According to Hamiltonian mechanics: phase space diagram relates the variables q and p

> q = position = x $p = momentum = \gamma mv = mc\gamma\beta_x$

Liouvilles Theorem: $\int p \, dq = const$

for convenience (i.e. because we are lazy bones) we use in accelerator theory:

$$x' = \frac{dx}{ds} = \frac{dx}{dt}\frac{dt}{ds} = \frac{\beta_x}{\beta}$$
 where $\beta_x = v_x/c$

$$\int p \, dq = mc \int \gamma \beta_x \, dx$$

$$\int p \, dq = mc \gamma \beta \int x' \, dx$$

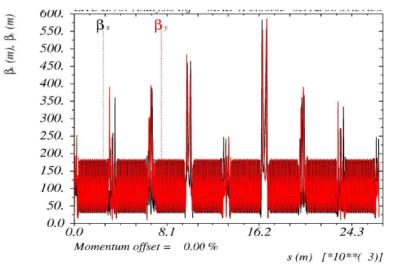

$$\Rightarrow \quad \varepsilon = \int x' \, dx \propto \frac{1}{\beta \gamma}$$
the beam emittance shrinks during acceleration $\varepsilon \sim 1/\gamma$

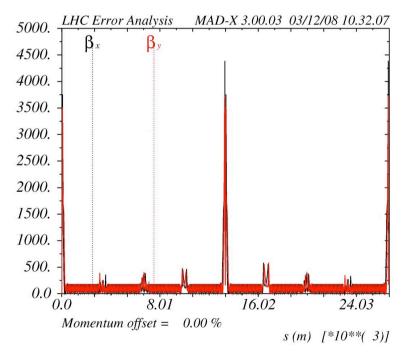

Nota bene:

1.) A proton machine ... or an electron linac ... needs the highest aperture at injection energy !!! as soon as we start to accelerate the beam size shrinks as $\gamma^{-1/2}$ in both planes.

 $\sigma = \sqrt{\varepsilon\beta}$

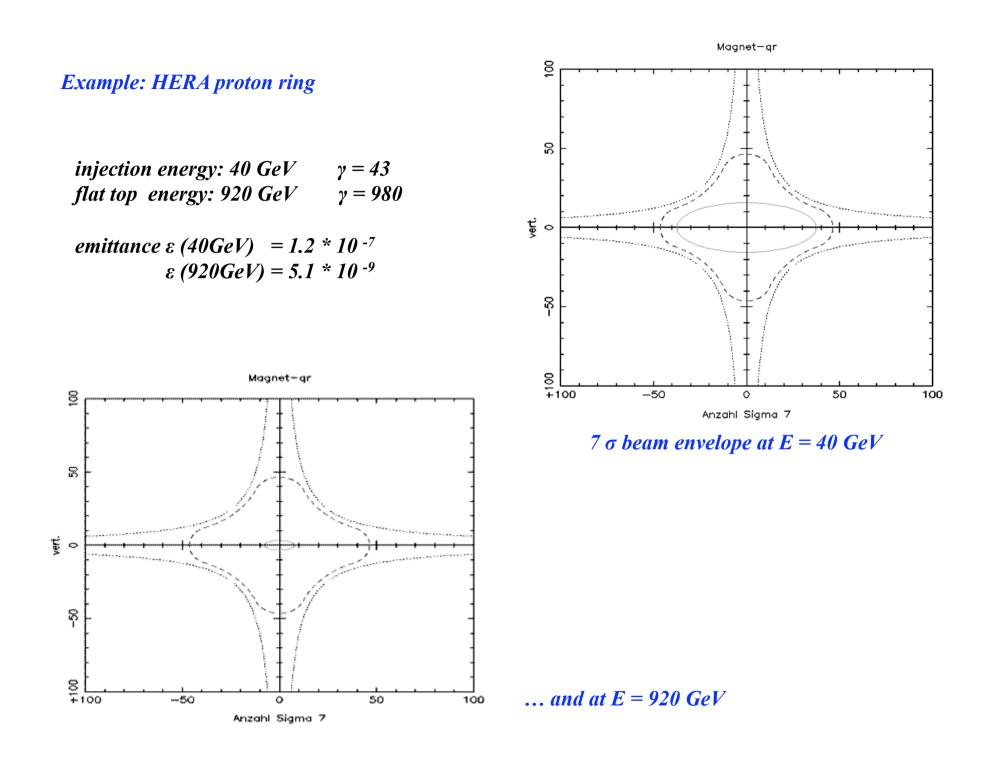

- 2.) At lowest energy the machine will have the major aperture problems, \rightarrow here we have to minimise $\hat{\beta}$
- 3.) we need different beam optics adopted to the energy: A Mini Beta concept will only be adequate at flat top.

LHC mini beta optics at 7000 GeV

LHC injection optics at 450 GeV

12.) The " $\Delta p / p \neq 0$ " Problem

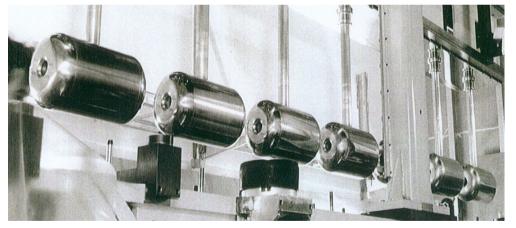

Quelle

Linear Accelerator

Energy Gain per "Gap":

 $\boldsymbol{W} = \boldsymbol{q} \, \boldsymbol{U}_0 \, \sin \omega_{\boldsymbol{R}\boldsymbol{F}} \boldsymbol{t}$

* **RF Acceleration:** multiple application of the same acceleration voltage; brillant idea to gain higher energies ... but changing acceleration voltage 1928, Wideroe

Strahl

500 MHz cavities in an electron storage ring

Driftröhren

HF-Sender

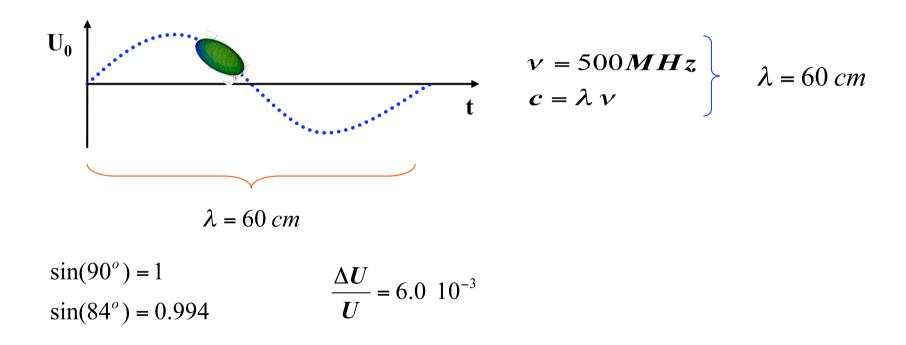

Problem: panta rhei !!!

(Heraklit: 540-480 v. Chr.)

Example: HERA RF:

 $\frac{\Delta p}{p} \approx 1.0 \ 10^{-3}$

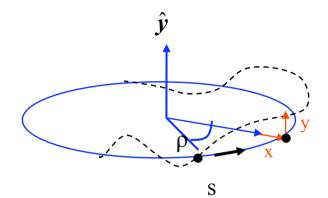

typical momentum spread of an electron bunch:

13.) Dispersion: trajectories for $\Delta p / p \neq 0$

Force acting on the particle

$$F = m \frac{d^2}{dt^2} (x + \rho) - \frac{mv^2}{x + \rho} = e B_y v$$

remember: $x \approx mm$, $\rho \approx m \dots \rightarrow$ develop for small x

$$m\frac{d^2x}{dt^2} - \frac{mv^2}{\rho}(1 - \frac{x}{\rho}) = eB_y v$$

consider only linear fields, and change independent variable: $t \rightarrow s$

$$\boldsymbol{B}_{y} = \boldsymbol{B}_{0} + \boldsymbol{x} \frac{\partial \boldsymbol{B}_{y}}{\partial \boldsymbol{x}}$$

$$x'' - \frac{1}{\rho}(1 - \frac{x}{\rho}) = \underbrace{e \ B_0}_{mv} + \underbrace{e \ x \ g}_{mv}$$

$$p = p_0 + \Delta p$$

... but now take a small momentum error into account !!!

Dispersion:

develop for small momentum error

$$\Delta \boldsymbol{p} \ll \boldsymbol{p}_0 \Longrightarrow \frac{1}{\boldsymbol{p}_0 + \Delta \boldsymbol{p}} \approx \frac{1}{\boldsymbol{p}_0} - \frac{\Delta \boldsymbol{p}}{\boldsymbol{p}_0^2}$$

$$\boldsymbol{x}'' + \frac{\boldsymbol{x}}{\rho^2} \approx \frac{\Delta \boldsymbol{p}}{\boldsymbol{p}_0} * \frac{(-\boldsymbol{e}\boldsymbol{B}_0)}{\boldsymbol{p}_0} + \boldsymbol{k} * \boldsymbol{x} = \frac{\Delta \boldsymbol{p}}{\boldsymbol{p}_0} * \frac{1}{\rho} + \boldsymbol{k} * \boldsymbol{x}$$

$$\mathbf{x}'' + \frac{\mathbf{x}}{\rho^2} - \mathbf{k}\mathbf{x} = \frac{\Delta \mathbf{p}}{\mathbf{p}_0} \frac{1}{\rho} \longrightarrow \qquad \mathbf{x}'' + \mathbf{x}(\frac{1}{\rho^2} - \mathbf{k}) = \frac{\Delta \mathbf{p}}{\mathbf{p}_0} \frac{1}{\rho}$$

Momentum spread of the beam adds a term on the r.h.s. of the equation of motion. \rightarrow *inhomogeneous differential equation.*

Dispersion:

$$x'' + x(\frac{1}{\rho^2} - k) = \frac{\Delta p}{p} \cdot \frac{1}{\rho}$$

general solution:

$$x(s) = x_h(s) + x_i(s)$$

 $\begin{cases} x_h''(s) + K(s) \cdot x_h(s) = 0 \\ x_i''(s) + K(s) \cdot x_i(s) = \frac{1}{\rho} \cdot \frac{\Delta p}{p} \end{cases}$

Normalise with respect to $\Delta p/p$:

$$D(s) = \frac{x_i(s)}{\frac{\Delta p}{p}}$$

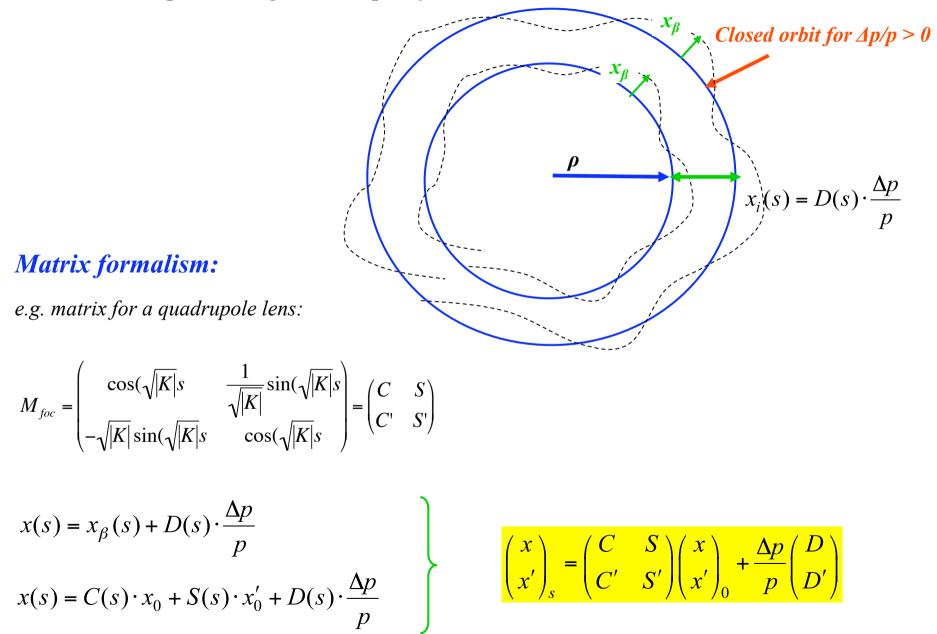

* is that special orbit, an ideal particle would have for $\Delta p/p = 1$

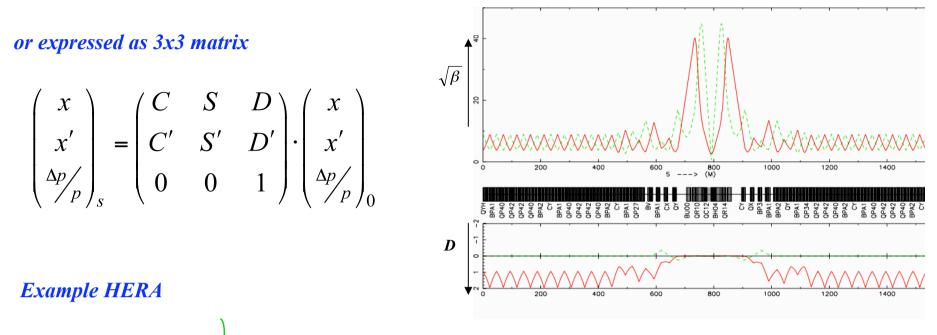

* the orbit of any particle is the sum of the well known x_{β} and the dispersion

* as D(s) is just another orbit it will be subject to the focusing properties of the lattice

Dispersion

Example: homogeneous dipole field

$$x_{\beta} = 1 \dots 2 mm$$
$$D(s) \approx 1 \dots 2 m$$
$$\Delta p / p \approx 1 \cdot 10^{-3}$$

Amplitude of Orbit oscillation contribution due to Dispersion ≈ beam size → Dispersion must vanish at the collision point

Calculate D, D'

$$D(s) = S(s) \int_{s0}^{s1} \frac{1}{\rho} C(\tilde{s}) d\tilde{s} - C(s) \int_{s0}^{s1} \frac{1}{\rho} S(\tilde{s}) d\tilde{s}$$

(proof: see appendix)

Example: Drift

$$M_{Drif t} = \begin{pmatrix} 1 & l \\ 0 & 1 \end{pmatrix}$$

$$D(s) = S(s) \int_{s_0}^{s_1} \frac{1}{\rho} C(\tilde{s}) d\tilde{s} - C(s) \int_{s_0}^{s_1} \frac{1}{\rho} S(\tilde{s}) d\tilde{s}$$

$$= 0$$

$$= 0$$

Example: Dipole

$$M_{foc} = \begin{pmatrix} \cos(\sqrt{|K|}s) & \frac{1}{\sqrt{|K|}} \sin(\sqrt{|K|}s) \\ -\sqrt{|K|} \sin(\sqrt{|K|}s) & \cos(\sqrt{|K|}s) \end{pmatrix}_0 \qquad \qquad K = \frac{1}{\rho^2}$$

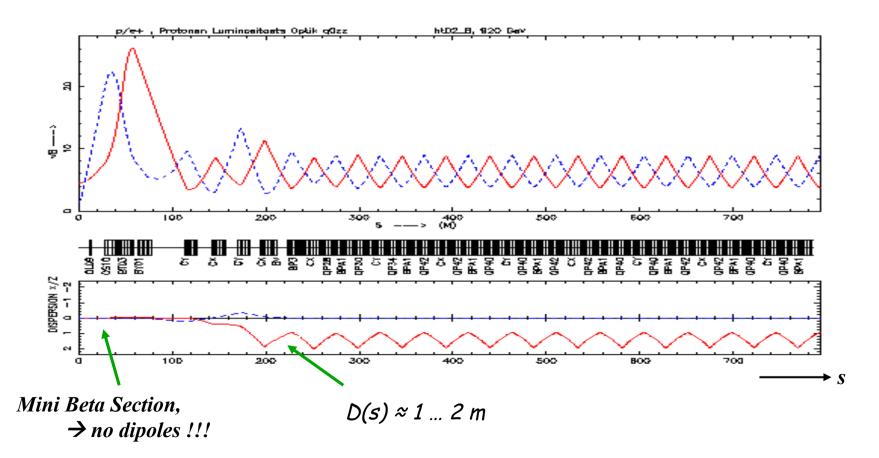

$$M_{Dipole} = \begin{pmatrix} \cos \frac{l}{\rho} & \rho \sin \frac{l}{\rho} \\ -\frac{1}{\rho} \sin \frac{l}{\rho} & \cos \frac{l}{\rho} \end{pmatrix} \longrightarrow D(s) = \rho \cdot (1 - \cos \frac{l}{\rho}) \\ D'(s) = \sin \frac{l}{\rho}$$

Example: Dispersion, calculated by an optics code for a real machine

$$x_D = D(s) \frac{\Delta p}{p}$$

* D(s) is created by the dipole magnets

... and afterwards focused by the quadrupole fields

Dispersion is visible

dedicated energy change of the stored beam

→ closed orbit is moved to a dispersions trajectory

$$x_{D} = D(s) * \frac{\Delta p}{p}$$

Attention: at the Interaction Points we require D=D'=0 HERA Standard Orbit

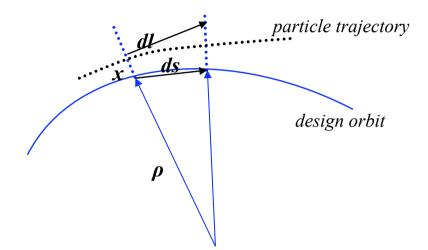

HERA Dispersion Orbit

14.) Momentum Compaction Factor: a_p

particle with a displacement x to the design orbit \rightarrow path length dl ...

$$\frac{dl}{ds} = \frac{\rho + x}{\rho}$$
$$\Rightarrow dl = \left(1 + \frac{x}{\rho(s)}\right) ds$$

circumference of an off-energy closed orbit

$$l_{\Delta E} = \oint dl = \oint \left(1 + \frac{x_{\Delta E}}{\rho(s)}\right) ds$$

remember:

$$x_{\Delta E}(s) = D(s) \frac{\Delta p}{p}$$

$$\delta l_{\Delta E} = \frac{\Delta p}{p} \oint \left(\frac{D(s)}{\rho(s)} \right) ds$$

* The lengthening of the orbit for off-momentum particles is given by the dispersion function and the bending radius.

Definition:

$$\frac{\delta l_{\varepsilon}}{L} = \alpha_p \frac{\Delta p}{p}$$

$$\Rightarrow \alpha_p = \frac{1}{L} \oint \left(\frac{D(s)}{\rho(s)} \right) ds$$

For first estimates assume:

$$\frac{1}{\rho} = const.$$

$$\int_{dipoles} D(s) ds \approx l_{\Sigma(dipoles)} \cdot \langle D \rangle_{dipoles}$$

$$\alpha_{p} = \frac{1}{L} l_{\Sigma(dipoles)} \cdot \langle D \rangle \frac{1}{\rho} = \frac{1}{L} 2\pi \rho \cdot \langle D \rangle \frac{1}{\rho} \quad \Rightarrow \quad \alpha_{p} \approx \frac{2\pi}{L} \langle D \rangle \approx \frac{\langle D \rangle}{R}$$

Assume: $v \approx c$

$$\Rightarrow \quad \frac{\delta T}{T} = \frac{\delta l_{\varepsilon}}{L} = \alpha_p \frac{\Delta p}{p}$$

 a_p combines via the dispersion function the momentum spread with the longitudinal motion of the particle.

15.) Gradient Errors

Matrix in Twiss Form

Transfer Matrix from point "0" in the lattice to point "s":

 $\beta(s+L) = \beta(s)$

 $\alpha(s+L) = \alpha(s)$

 $\gamma(s+L) = \gamma(s)$

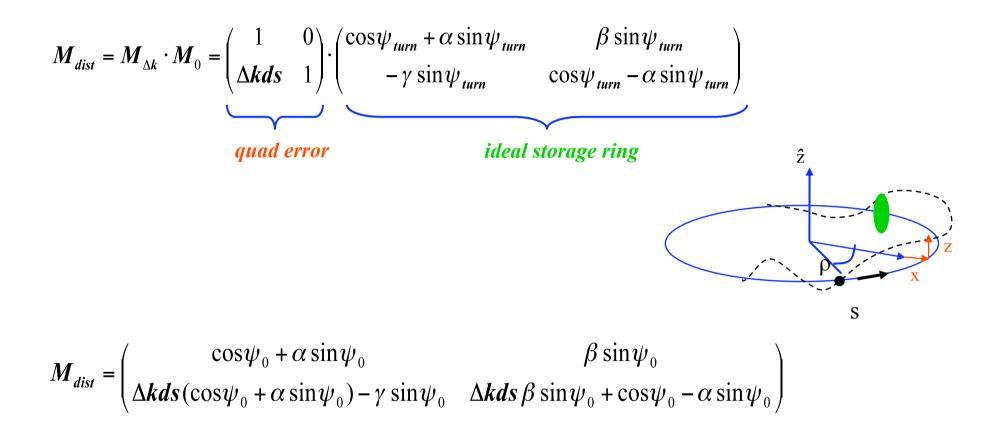

$$M(s) = \begin{pmatrix} \sqrt{\frac{\beta_s}{\beta_0}} (\cos\psi_s + \alpha_0 \sin\psi_s) & \sqrt{\beta_s\beta_0} \sin\psi_s \\ \frac{(\alpha_0 - \alpha_s)\cos(\psi_s - (1 + \alpha_0\alpha_s)\sin\psi_s)}{\sqrt{\beta_s\beta_0}} & \sqrt{\frac{\beta_0}{\beta_s}} (\cos(\psi_s - \alpha_0 \sin\psi_s)) \end{pmatrix}$$

For one complete turn the Twiss parameters have to obey periodic bundary conditions:

$$\boldsymbol{M}(\boldsymbol{s}) = \begin{pmatrix} \cos\psi_{turn} + \alpha_{s}\sin\psi_{turn} & \beta_{s}\sin\psi_{turn} \\ -\gamma_{s}\sin\psi_{s} & \cos\psi_{turn} - \alpha_{s}\sin\psi_{turn} \end{pmatrix}$$

Quadrupole Error in the Lattice

optic perturbation described by thin lens quadrupole

rule for getting the tune

$$Trace(M) = 2\cos\psi = 2\cos\psi_0 + \Delta k ds\beta \sin\psi_0$$

Quadrupole error \rightarrow Tune Shift

$$\psi = \psi_0 + \Delta \psi$$
 \longrightarrow $\cos(\psi_0 + \Delta \psi) = \cos \psi_0 + \frac{\Delta k ds \beta \sin \psi_0}{2}$

remember the old fashioned trigonometric stuff and assume that the error is small !!!

$$\cos\psi_{0} \cos\Delta\psi - \sin\psi_{0} \sin\Delta\psi = \cos\psi_{0} + \frac{kds\beta\sin\psi_{0}}{2}$$

$$\approx 1 \qquad \approx \Delta\psi$$

$$\Delta \psi = \frac{kds\,\beta}{2}$$

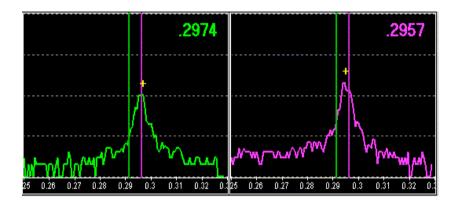

and referring to Q instead of ψ :

$$\psi = 2\pi Q$$

$$\Delta \boldsymbol{Q} = \int_{s_0}^{s_0+l} \frac{\Delta \boldsymbol{k}(s)\beta(s)ds}{4\pi}$$

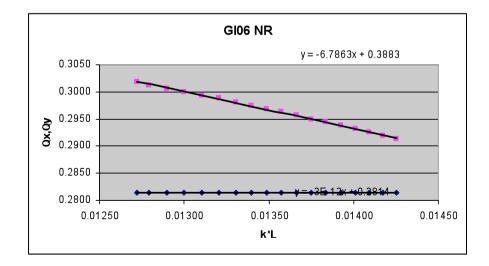

- ! the tune shift is proportional to the β -function at the quadrupole
- If field quality, power supply tolerances etc are much tighter at places where β is large
- III mini beta quads: β ≈ 1900 m arc quads: β ≈ 80 m
- IIII β is a measure for the sensitivity of the beam

a quadrupol error leads to a shift of the tune:

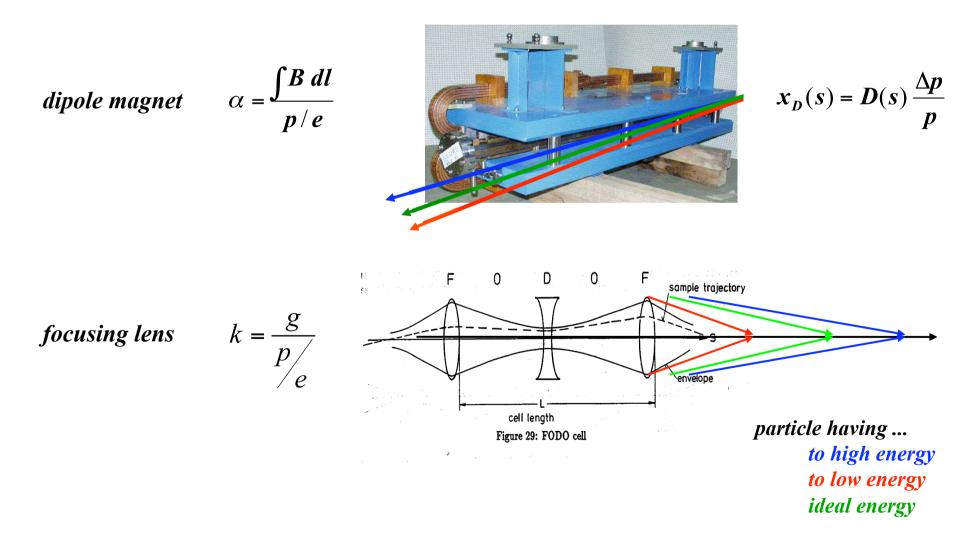

$$\Delta Q = \int_{s0}^{s0+l} \frac{\Delta k \beta(s)}{4\pi} ds \approx \frac{\Delta k l_{quad} \overline{\beta}}{4\pi}$$

Example: measurement of β in a storage ring: tune spectrum

16.) Chromaticity: A Quadrupole Error for $\Delta p/p \neq 0$

Influence of external fields on the beam: prop. to magn. field & prop. zu 1/p

Chromaticity: Q'

$$k = \frac{g}{\frac{p}{e}} \qquad \qquad p = p_0 + \Delta p$$

in case of a momentum spread:

$$k = \frac{eg}{p_0 + \Delta p} \approx \frac{e}{p_0} (1 - \frac{\Delta p}{p_0}) g = k_0 + \Delta k$$
$$\Delta k = -\frac{\Delta p}{p_0} k_0$$

... which acts like a quadrupole error in the machine and leads to a tune spread:

$$\Delta \boldsymbol{Q} = -\frac{1}{4\pi} \frac{\Delta \boldsymbol{p}}{\boldsymbol{p}_0} \boldsymbol{k}_0 \boldsymbol{\beta}(\boldsymbol{s}) \boldsymbol{ds}$$

definition of chromaticity:

$$\Delta Q = Q' \quad \frac{\Delta p}{p} \quad ; \qquad Q' = -\frac{1}{4\pi} \oint k(s)\beta(s)ds$$

... what is wrong about Chromaticity:

Problem: chromaticity is generated by the lattice itself !!

Q' is a number indicating the size of the tune spot in the working diagram, Q' is always created if the beam is focussed

 \rightarrow it is determined by the focusing strength k of all quadrupoles

$$Q' = -\frac{1}{4\pi} \oint k(s)\beta(s)ds$$

k = quadrupole strength $\beta = beta function indicates the beam size ... and even more the sensitivity of the beam to external fields$

Example: LHC

Q' = 250 $\Delta p/p = +/- 0.2 *10^{-3}$ $\Delta Q = 0.256 \dots 0.36$

→Some particles get very close to resonances and are lost

in other words: the tune is not a point it is a pancake

Correction of Q':

1.) sort the particles acording to their momentum

$$x_D(s) = D(s)\frac{\Delta p}{p}$$

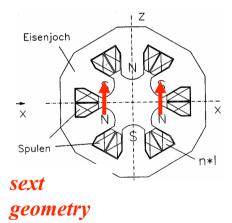

2.) apply a magnetic field that rises quadratically with x (sextupole field)

$$B_{x} = \tilde{g}xz$$

$$B_{z} = \frac{1}{2}\tilde{g}(x^{2} - z^{2})$$

$$\frac{\partial B_{x}}{\partial z} = \frac{\partial B_{z}}{\partial x} = \tilde{g}x$$
linear rising "gradient":

Sextupole Magnets:

Eisenjoch V Spulen N S S N n*i geometry normalised quadrupole strength:

$$k_{sext} = \frac{\tilde{g}x}{p/e} = m_{sext.}x$$

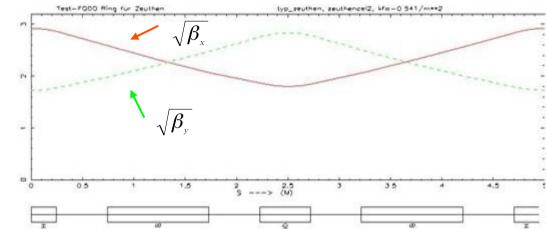

$$k_{sext} = m_{sext.} D \frac{\Delta p}{p}$$

corrected chromaticity:

$$\mathbf{Q}' = -\frac{1}{4\pi} \oint \left\{ \mathbf{K}(s) - \mathbf{m}\mathbf{D}(s) \right\} \beta(s) ds$$

Chromaticity in the FoDo Lattice

$$Q' = \frac{-1}{4\pi} * \oint k(s)\beta(s) \, ds$$

β-Function in a FoDo

$$\hat{\beta} = \frac{(1 + \sin\frac{\psi_{cell}}{2})L}{\sin\psi_{cell}} \qquad \qquad \vec{\beta} = \frac{(1 - \sin\frac{\psi_{cell}}{2})L}{\sin\psi_{cell}}$$

$$Q' = \frac{-1}{4\pi} N^* \frac{\hat{\beta} - \bar{\beta}}{f_Q}$$
$$Q' = \frac{-1}{4\pi} N^* \frac{1}{f_Q}^* \left\{ \frac{L(1 + \sin\frac{\psi_{cell}}{2}) - L(1 - \sin\frac{\psi_{cell}}{2})}{\sin\mu} \right\}$$

using some TLC transformations ... ξ can be expressed in a very simple form:

$$Q' = \frac{-1}{4\pi} N * \frac{1}{f_Q} * \frac{2L\sin\frac{\psi_{cell}}{2}}{\sin\psi_{cell}}$$

$$Q' = \frac{-1}{4\pi} N^* \frac{1}{f_Q}^* \frac{L \sin \frac{\psi_{cell}}{2}}{\sin \frac{\psi_{cell}}{2} \cos \frac{\psi_{cell}}{2}}$$
remember ...
$$\sin x = 2 \sin \frac{x}{2} \cos \frac{x}{2}$$

$$Q_{cell}' = \frac{-1}{4\pi f_Q} * \frac{L \tan \frac{\psi_{cell}}{2}}{\sin \frac{\psi_{cell}}{2}}$$

putting ...

$$\sin\frac{\psi_{cell}}{2} = \frac{L}{4f_Q}$$

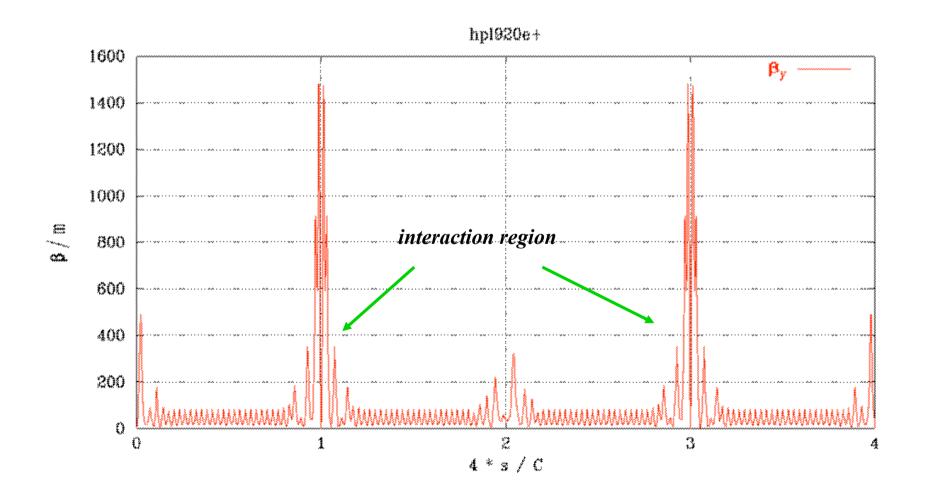

$$Q_{cell}' = \frac{-1}{\pi} * \tan \frac{\psi_{cell}}{2}$$

contribution of one FoDo Cell to the chromaticity of the ring:

Chromaticity

$$Q' = -\frac{1}{4\pi} \oint K(s)\beta(s)ds$$

question: main contribution to ξ in a lattice ... ?

17.) Résumé:

beam rigidity:	$B \cdot \rho = \frac{p}{q}$
bending strength of a dipole:	$\frac{1}{\rho} \left[m^{-1} \right] = \frac{0.2998 \cdot B_0(T)}{p(GeV/c)}$
focusing strength of a quadrupole:	$k\left[m^{-2}\right] = \frac{0.2998 \cdot g}{p(GeV/c)}$
focal length of a quadrupole:	$f = \frac{1}{k \cdot l_q}$
equation of motion:	$x'' + Kx = \frac{1}{\rho} \frac{\Delta p}{p}$
matrix of a foc. quadrupole:	$x_{s2} = M \cdot x_{s1}$
$\begin{pmatrix} & & & \\ & & & \\ & & & \end{pmatrix}$	(10)

$$M = \begin{pmatrix} \cos\sqrt{|K|}l & \frac{1}{\sqrt{|K|}}\sin\sqrt{|K|}l \\ -\sqrt{|K|}\sin\sqrt{|K|}l & \cos\sqrt{|K|}l \end{pmatrix} , \qquad M = \begin{pmatrix} 1 & 0 \\ \frac{1}{f} & 1 \end{pmatrix}$$

 $\varepsilon \propto \frac{1}{\beta \gamma}$ Resume': beam emittance: $\beta(s) = \beta_0 - 2\alpha_0 s + \gamma_0 s^2$ beta function in a drift: $\beta(s) = \beta_0 + \frac{s^2}{\beta_0}$ \dots and for $\alpha = 0$
