## Description

### Micromegas [1, 2]

- MICRO-MEsh-GAseous Structure
- Gaseous detector
- Charged particles ionise gas
- Drift voltage to catch electrons
- Amplification voltage (high) to multiply ionisation

### Advantages

- High resolution  
( $\approx 50 \mu\text{m}$ , down to  $12 \mu\text{m}$  [2])
- Fast signal ( $\approx 100 \text{ ns}$  [2])
- Radiation hardness

Proposed to be used for the ATLAS NSW (endcap muon spectrometer) in phase-I upgrade

The micro-mesh

# Micromegas

(a) Sketch of Micromegas functioning [3]

(b) Insight in Micromegas [4]

- Tracks produce signal in multiple strips (cluster)

- Use timing to get track angle

TEST BEAM SETUP Jun2013 (10.06.2013 – 19.06.2013), small Freiburg frame

- Beam: Electrons with 1-5 GeV
- Magnetic field: 0-1 T in x-direction
- Different angles possible for certain chambers

# Analysis

- Detector Alignment
  - Crucial for resolution calculation
  - Using  $\chi^2$  minimisation:  $\chi^2 = \sum_{\text{tracks}} \chi_i^2(\{y_d\}, \{z_d\})$
  - y-alignment: Easily done
  - z-alignment: Very difficult
    - Did not converge
    - Solution: Iterative alignment (select best events, align, repeat)
  - Alignment tested with simulated data
  - Other alignments conceivable (angles, etc.) presumably difficult
- Observables
  - Detector resolution
  - Particle momenta (in magnetic fields)
  - Beam properties
    - Beam energy
    - Size / angular spread

**Results**

End

# Results

Run 10102: 22137 events  $E = 5$  GeV,  $B = 0$ ,  $\theta = 0$

(a) Track probability distribution

(b) Detector resolution

Run 10204: 20626 events  $E = 2$  GeV,  $B = 0.8$  T,  $\theta = 0$

(c) Momentum resolution

# Outlook

What to do next?

Several ideas:

- Regard Lorentz angle in magnetic field
- Try alternative way of hit reconstruction ( $\mu$ TPC)
- Use angular information

$$\chi^2 = \sum_{\text{tracks}} \chi_i^2(\{y_d\}, \{z_d\}) \quad (1)$$

**Problem:** Small percentage of tracks seems to be completely wrong, disturb the alignment.

**Possible solution:** Exclude tracks with very high  $\chi^2$  probability.

**However:** Introduces a bias;  $\chi^2$  depends on the alignment. We align using those tracks, that already fit best to the alignment we currently have...

To avoid this bias: An iterative approach

1. Select best 90% of all tracks (according to  $\chi^2$ -probability).  
Typically 30% of the tracks have a very low  $\chi^2$  probability ( $10^{-3}$ ).
2. Align the detectors with  $\chi^2$  minimisation.
3. GOTO 1. (repeat 5 to 10 times)
