Outline

❖ General Introduction

- Classical Gas Detectors

❖ State of the Art

- MicroMesh Gaseous Structure and Gas Electron Multiplier

❖ Research & Development

- Spiral Detector

Classical Gas Detectors

WHAT ARE THEY?

Gaseous detectors are **radiation detection instruments** designed:

- to **point out** the **presence** of ionizing particles (p, e, μ , ...);
- to **measure** together with B-field, dE/dx , etc., their **properties** (momentum, charge, ...).

HOW DO THEY WORK?

They use the **ionizing effect** produced by the **incoming ionizing particle** onto a **gas-filled sensor**. The charged particle, passing through the gas, loses a small fraction of its energy producing various collateral effects, such as the ionization of the gas atoms or molecules. The resulting electrons and ions, moving in an external electrical field, cause a **current flow** which can be measured.

Classical Gas Detectors

ADVANTAGES

- Large areas at low prices;
- Flexible geometries;
- Good spatial and energy resolution.

LIMITATIONS

- Rate capabilities <10 kHz/cm² (due to the long ion drift time and the space charge density which reduces the effective electric field);
- Reduction of the gain;
- Distortion of the drift path.

Micro-Pattern Gas Detector

- Plane geometry with electron multiplication close to its electron drift direction in both directions of the chamber plane
- E-field shape in drift regions similar to classic plane chambers (constant drift velocity)

Micro-Pattern Gas Detector

Introduced at the end of 1980s,
the **Micro-pattern Gas Detectors (MPGD)**
perform better than classic wire chambers.

They allow to achieve both
very good localization accuracy
and
high rate capability
that make this technology attractive for charged particle tracking at
high luminosity colliders.

During its evolution, Micro-Pattern Gas technology gave raise to many
different types of devices such as **Micro-Strip Gas Chambers (MSGC)**.

Micro-Strip Gas Chamber

MSGCs, having a small pitch between anode and cathode strips, are characterized by:

- fast ions collection;
- spatial resolution $\sim 50\mu\text{m}$;
- two track resolution $\sim 500\mu\text{m}$;
- high rate capability $\sim 10^6\text{ Hz/mm}$.

But... MSGCs are subjected to:

- slow degradation under sustained irradiation;
- rare but devastating occurrence of discharges.

Gas Electron Multiplier

Initially developed as a preamplifier stage for an MSGC, the **Gas Electron Multiplier (GEM)** became soon a detector on its own.

E field

Structure

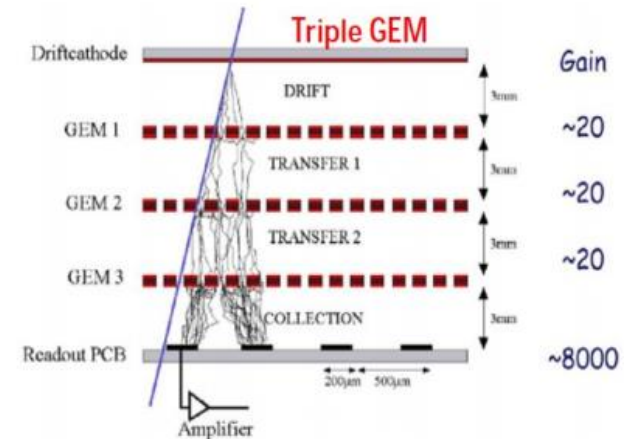

Production steps

(1999, F.Sauli)

Improved GEM

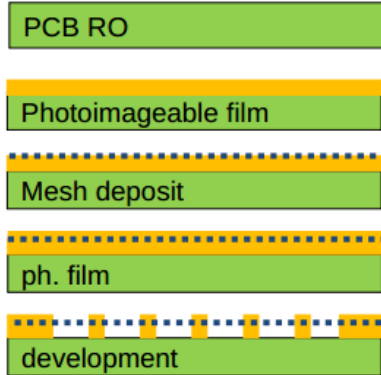

Spread of the avalanche over many active holes → reduction of spark probability

MicroMesh Gaseous Structure

Parallel plate chamber where the amplification takes place in a thin gap, separated from the conversion region by a fine metallic mesh.

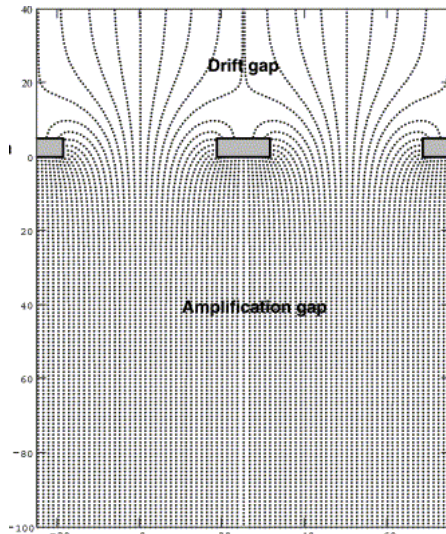

Production steps

Improved MM

E field

Resistive material:

not reduction of sparks but limit their impact on performance of the detector (HV drops become insignificant).

Strips instead of layer:

to avoid charge spreading and to keep the area affected by discharges as small as possible.

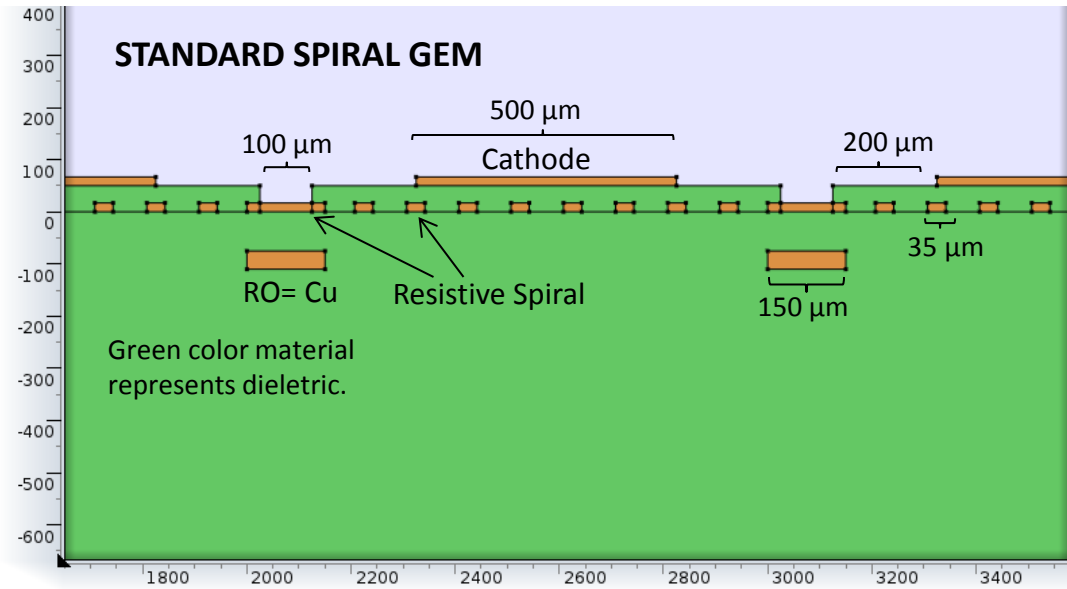

**GEM and
MicroMEGAS
spark...**

**What can we
do?**

Spiral Detector

$$V_{\text{tot}} = V_0 - RI,$$
 so if R is very high,
 when there is a current I
 (and this happens just in the sparks),
 the value RI is subtracted to V_0 and the
 potential V_{tot} (from which we obtained the
 electric field E) slows down,
 so the spark is stopped
 and the detector is safe.

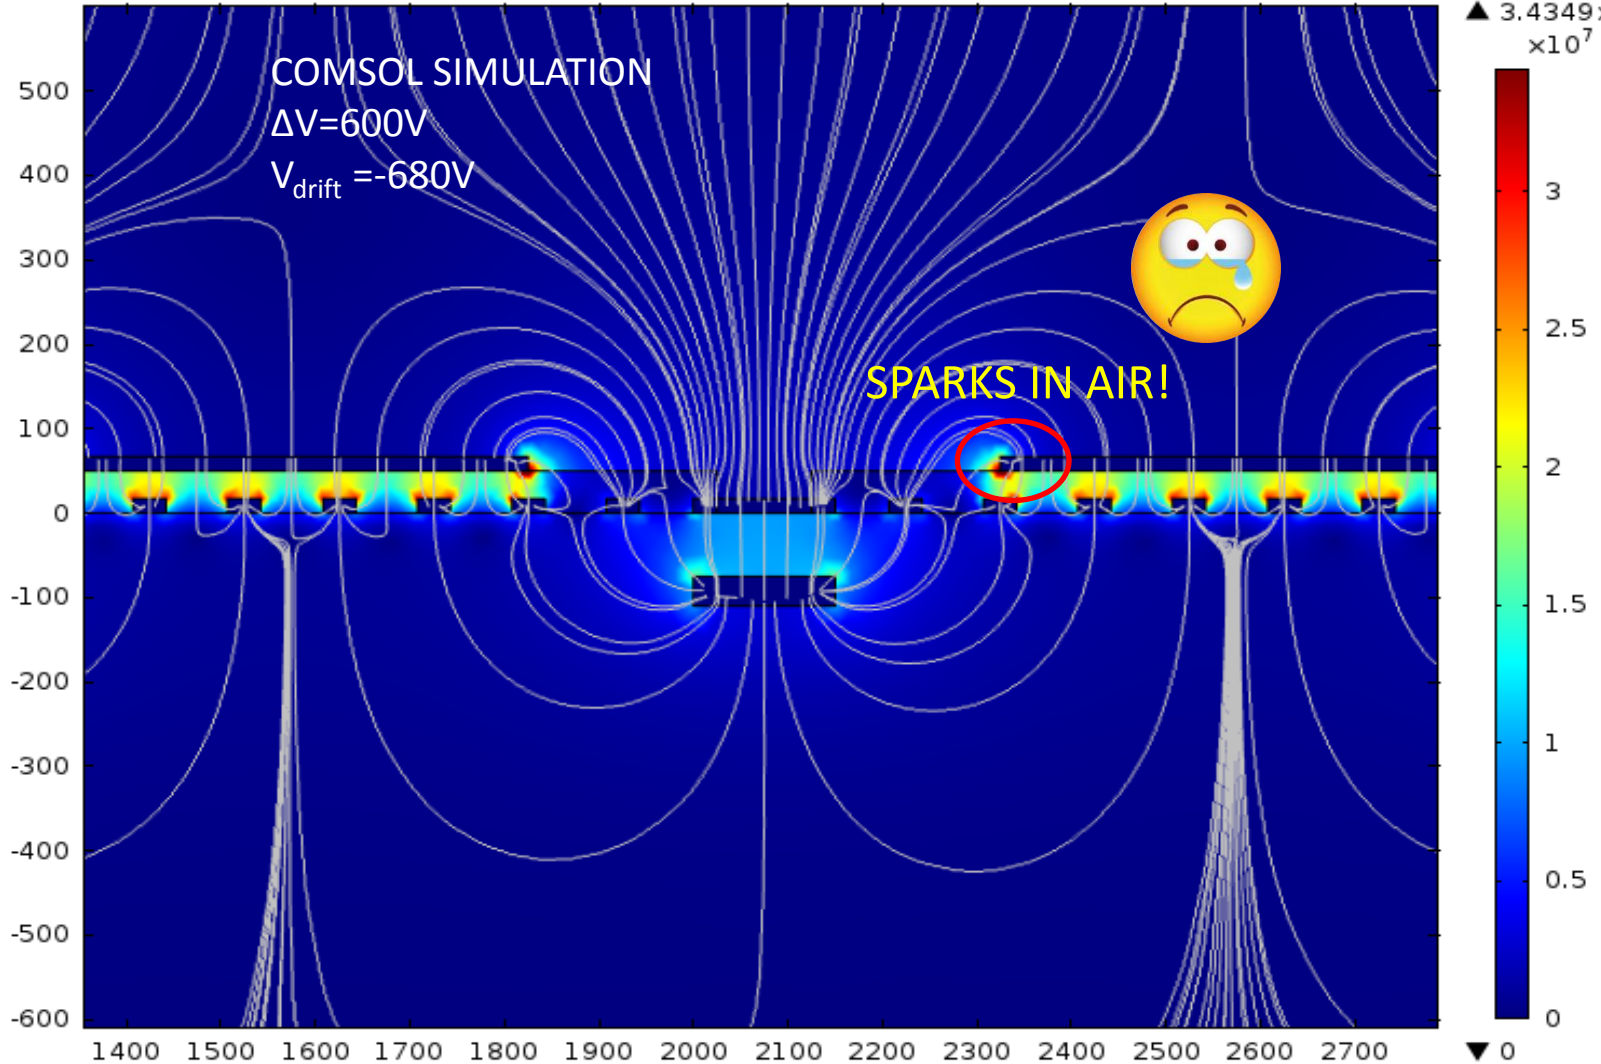

The spirals are connected all together and the presence of resistive material on the whole path allow us to obtain very high electrical resistance $R \sim 3 \text{ G}\Omega$.
