# Comments on Induced Signals in Charge Readout

Josh Renner UC Berkeley / LBNL RD51 Mini-Week, WG4 April 25, 2013

- Garfield and Garfield++ support simulations of electron/ion drift in finite-element fields and corresponding calculation of induced signals
- Purpose of these comments:
  - describe components of a charge readout signal
  - demonstrate in detail the time development of an induced signal
- Will make use of Garfield++, Gmsh [1] and Elmer [2]

Signal readout: weighting fields

From RD51 Mini-Week WG4, 01/30/13

Induced signals

- A charge moving toward an electrode induces a current; product of [1]:

- $\rightarrow$  the charge q
- $\rightarrow$  the velocity of the moving charge v(t)
- → the weighting field  $F = -\nabla V$ , for V = 1 on electrode, V = 0 all other conductors

Josh Renner, RD51 Mini-Week WG4, 04/25/13

# Example: LEM readout + attachment

Modified from RD51 Mini-Week WG4, 01/30/13

LEM-based readout process

- → single-electron avalanche
- → e- drift towards readout electrode
- → some e- attach along the way and drift as negative ions
- → meanwhile positive ions (not shown) drift back through the LEM
- Simulate in Garfield++:
  - Ar (30%) CO<sub>2</sub> (26%) O<sub>2</sub> (4%)
  - single e- incident on LEM produces an avalanche
  - drift a positive ion from each point of ionization
  - drift a negative ion from each point of e- attachment

Josh Renner, RD51 Mini-Week WG4, 04/25/13

**Collaborators**: Mike Heffner and Melinda Sweany (LLNL)

# Example: LEM readout with attachment

#### From RD51 Mini-Week WG4, 01/30/13

• Ion component (+ and -) of induced signal

Josh Renner, RD51 Mini-Week WG4, 04/25/13

# Comments on induced signals

- Induced signals: signal components
  - Ionization commonly read out as an induced signal
  - Depending on proximity of ionization to the electrode, the drifting ion may contribute  $\geq$  the electron itself

Josh Renner, RD51 Mini-Week WG4, 04/25/13

Comments on induced signals

- Induced signals: charge neutralization
  - No "spike" of current is produced on contact with the electrodes
  - A net charge of -1 has already been observed through the induction process

# Comments on induced signals

- Induced signals: charge neutralization
  - No "spike" of current is produced on contact with the electrodes
  - A net charge of -1 has already been observed through the induction process

Assuming ionization occurred far away from the electrode:

- LEM geometry (THGEM #9 of [1])
- 190 torr Ar/CO<sub>2</sub> (70/30)
- Single electron dropped above LEM and drifted through LEM hole to produce an avalanche
- Example shown: 25
  electrons from the avalanche
  reached the readout plane
  (note: only considering
  electron and positive ion
  signals 4 attached
  electrons are not drifted as
  negative ions)

# Conclusions:

- Ionization is read out by signals induced on electrodes, not as pulses produced suddenly upon neutralization of electrons
- Depending on the location of the ionization, the signal induced by the drifting ion may be larger than that induced by the electron being collected
- This process can be simulated in detail using finite element weighting field maps
