# Non-Intact Protons

Origin and  
Properties of  
Forward Protons  
at the LHC

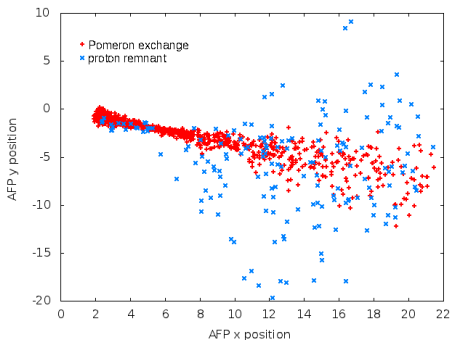

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- AFP detectors: planned for ATLAS, around 220 m from ATLAS IP, after several LHC magnets
- AFP aim – measure protons originating from diffractive or electromagnetic interaction
- Other protons can be seen, if energy large enough

# Intact and Non-Intact Protons

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

Summary and Conclusions

Elastic:

Single diffractive:

Central diffractive:

Double diffractive:

Non-diffractive:

- Intact protons in: elastic (EL), single diffractive (SD) and central diffractive (CD) processes
- Proton remnants (or dissociates states) present in: single diffractive, double diffractive and non-diffractive processes
- Possible to find a proton in the remnant (recombination)

# Probability of AFP Tag

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

Summary and Conclusions

$\sigma$ (mb)	ND	SD	DD	CD	Total
<b>Pythia 6</b>	55	14	10	–	79
<b>Pythia 8</b>	58	13	9	–	79
<b>Phojet</b>	68	11	4	1	84

Now, new diffraction model in Pythia 8 – MBR (Minimum-Bias Rockefeller) – contains also the central diffractive component.

- AFP acceptance:  $0.02 < \xi < 0.12$
- Double tag: protons on both sides from a single interaction

	ND	SD	DD	CD	Total
<b>AFP single tag probability (%)</b>					
<b>Pythia 6</b>	0.4	11.0	3.2	–	2.8
<b>Pythia 8</b>	0.2	11.0	2.4	–	2.2
<b>Phojet</b>	1.7	13.0	2.0	38	3.6
<b>AFP double tag probability (%)</b>					
<b>Pythia 6</b>	0.004	0.4	0.01	–	0.06
<b>Pythia 8</b>	0.001	0.07	0.05	–	0.02
<b>Phojet</b>	0.1	0.6	0.03	11	0.29

# Double Tag Probability With Pile-up

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

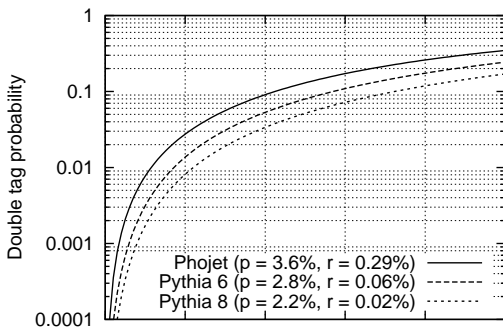

Summary and Conclusions

Probability of having a double tag event for average pile-up multiplicity  $\mu$  (combinatorial formula convoluted with a Poisson distribution):

$$P(\mu) = 1 - 2e^{-\mu p} + e^{-\mu(2q-r)}$$

where

- $p$  – single tag probability
- $r$  – double tag probability
- Background to hard DPE processes

# Pile-up

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

Summary and Conclusions

Predictions from different generators:

- Single tag probability important at high  $\mu$
- For special runs double tag probability dominant
- Non-intact protons may affect measurements with double tag

Effects of  $p$  and  $r$ :

# Contents

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- 1 Pile-up Background
- 2 Direct background
- 3 Forward proton production
- 4 Summary and Conclusions

# Direct Background to Hard Diffraction

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Previous slides – pile-up (overlay) background: diffractive hard process mimicked by non-diffractive hard process overlaid with soft processes with forward protons
- Non-intact protons can lead to background more directly: proton is present in proton remnants of a hard process
- ND  $\rightarrow$  SD
- May become a problem when  $\sigma_{\text{ND}} \gg \sigma_{\text{SD}}$
- Experimentally indistinguishable from hard diffraction (rapidity gap too small)
- Similarly, SD  $\rightarrow$  DPE
- Unlike for pile-up background, timing detectors do not help

# Magnetic Monopoles – Introduction

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Symmetrization of Maxwell equations
- Existence of magnetic monopoles implies electric charge quantisation:  $q_m q_e = \frac{1}{2} \hbar c$
- $q_e = 1/\sqrt{137} \rightarrow q_m = 68.5$
- Large charge – large coupling to photons
- Possible to produce in two-photon exchange
- Perturbative calculations not valid
- Final state:
  - annihilation to  $2\gamma$
  - form a monopolium state (can also annihilate)
  - trapped in beam pipe material
  - escape undetected
- Invisible monopoles – forward protons + empty all other detectors

# Background to Invisible Monopoles – Double Diffraction

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Large Rapidity Gap  $\rightarrow$  central detector does not see anything
- Protons both in  $X$  and  $Y$  states
- Probability between  $10^{-5}$  and  $10^{-4}$
- Huge cross section compared to any hard process, including monopoles

# Event Record Example

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

# Kinematics of the Forward Proton

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Dimensionless fractional momentum loss  $\xi$ :

$$\xi = \frac{p_0 - p}{p_0},$$

where  $p_0$  – beam momentum

- $\xi = 0$  for elastic protons ( $p = p_0$ )
- $0 < \xi < 1$  for diffraction
- $\xi$  distribution steeply falling (typically  $\sim 1/\xi$ )
- For central production  $M = \sqrt{s\xi_1\xi_2}$
- One is interested in relatively small values of  $\xi$ ,  
e.g. ALFA:  $\xi < 0.2$ , AFP:  $0.02 < \xi < 0.12$
- Interpretation as “momentum loss” only for diffractive protons, but mathematically valid for all particles

# Proton Production in $pp$ Interactions

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Diffractively scattered protons – peak at  $\xi = 0$
- All processes – peak at  $\xi = 1 \rightarrow$  non-intact protons
- $t$  distribution steeper for diffractive processes

# Protons in SD

Origin and  
Properties of  
Forward Protons  
at the LHC

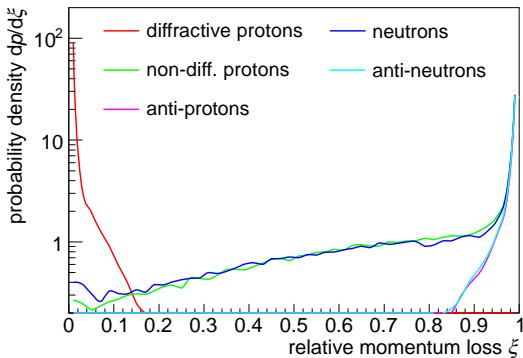

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

Diffractive (intact) vs non-diffractive (non-intact) proton – MC information

Distributions for non-diffractive protons and neutrons equal – isospin symmetry (similarly for anti-protons and anti-neutrons)

Distributions of all barions at  $\xi \rightarrow 1$

# Protons in SD

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

Summary and Conclusions

Three mechanisms of production:

- diffractive ( $\xi < 0.1, \eta \sim 11$ )
- "baryon conservation" ( $0.1 < \xi < 0.9, \eta \sim 10$ )
- "pair production" ( $\xi > 0.9, \eta < 9$ )

# $\xi$ Distribution in Different Processes

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

Summary and Conclusions

ND:

DD:

SD:

Non-intact proton distribution in SD and DD similar

Steeper distribution in ND – more difficult to recombine back to a proton

# Difference Between Generators

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Large impact of hadronisation model
- To be studied in more detail ...

# Hard Processes

Origin and Properties of Forward Protons at the LHC

R. Staszewski

Pile-up Background

Direct background

Forward proton production

Summary and Conclusions

Non-diffractive  $W$

Single diffractive  $W$

- ND  $W$  – Pythia 6, SD  $W$  – Herwig++
- Distribution steeper than before, because  $W$  is produced from quarks – even more difficult to recombine
- Important background for  $\xi > 0.2$
- May be negligible at LHC, but probably large uncertainty

# Summary and Conclusions

Origin and  
Properties of  
Forward Protons  
at the LHC

R. Staszewski

Pile-up  
Background

Direct  
background

Forward proton  
production

Summary and  
Conclusions

- Three mechanism for proton production
  - For  $\xi > 0.1$  non-diffractive mechanism shows up
  - Single and double tag events
  - Gap too small to distinguish from true diffractive events
- 
- Interesting, but difficult to measure – timing detectors probably needed to reject backgrounds
  - Plans:
    - sensitivity to hadronisation models
    - invisible magnetic monopoles (or other particles)
    - cosmic air shower physics?
