

# **QUARK MODELS**

Vladimir Galkin

Russian Academy of Sciences, Moscow, Russia

(in collaboration with Dietmar Ebert and Rudolf Faustov)

Flavour as a Window to New Physics at the LHC  
13 May 2008 — CERN, Geneva

- The constituent quark model (CQM) is one of the oldest phenomenological approaches describing hadrons as composite states of quarks
    - Large variety of quark models ranging from simple nonrelativistic models describing only some specific properties of hadrons (e.g. masses . . . ) to complicated relativistic ones attempting to give universal description of properties of various hadrons (light and heavy)
- ⇒ It is not possible to cover all of them in this talk

Thus only main common features of the modern **potential** models for the description of hadrons containing **heavy** quarks will be presented

# PLAN

## 1. Introduction

- Main assumptions/approximations of CQM
- Heavy mesons
- Heavy baryons
- Decays of heavy hadrons

## 2. Relativistic quark model

## 3. Selected CQM predictions

- $B_c$  meson
- Heavy baryons

## 4. Summary

## 1. INTRODUCTION

- Main assumptions of CQM:
  - Hadrons consist of valence coloured quarks:  
mesons -  $q\bar{q}$   
baryons -  $qqq$   
all other states (tetraquarks, pentaquarks . . . ) are called “exotic”
  - Sea quarks and gluons, complicated structure of QCD vacuum (condensates . . . ) etc.  $\implies$  constituent quark masses and confinement
  - Interaction between quarks in hadrons can be described by the potential which is usually assumed to be flavour independent
  - Hadrons are considered to be quasi-stable

## – Heavy mesons

- Bound state equation - typically Schrödinger-like:

$$[T + V]\Psi = E\Psi$$

$T$  - energy of free quarks

$V$  - potential energy

$\Psi$  - bound state wave function

$E$  - eigenvalue

### A. Kinematical structure

- Nonrelativistic models (Schrödinger equation)

$$T = \frac{\mathbf{p}^2}{2\mu}; \quad \mu = \frac{m_1 m_2}{m_1 + m_2}; \quad E = M - (m_1 + m_2)$$

$M$  - meson mass

$m_{1,2}$  - quark masses

- Relativistic models

a) Spinless Salpeter equation

$$T = \sqrt{\mathbf{p}^2 + m_1^2} + \sqrt{\mathbf{p}^2 + m_2^2}; \quad E = M$$

b) Quasipotential equation (rationalisation of square roots)

$$T = \frac{\mathbf{p}^2}{2\mu_R}; \quad E = \frac{b^2(M)}{2\mu_R}$$

relativistic reduced mass:

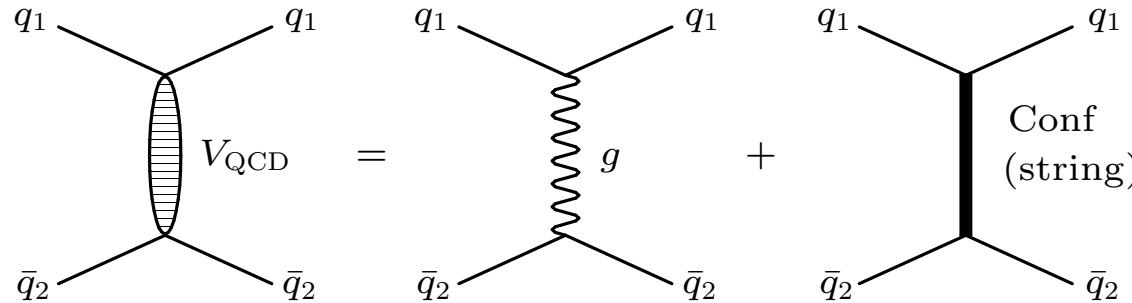

$$\mu_R = \frac{M^4 - (m_1^2 - m_2^2)^2}{4M^3} \xrightarrow{\text{weak binding}} \frac{m_1 m_2}{m_1 + m_2}$$

on-mass-shell relative momentum squared:

$$b^2(M) = \frac{[M^2 - (m_1 + m_2)^2][M^2 - (m_1 - m_2)^2]}{4M^2}$$

## B. Dynamics

- Quark-antiquark interaction potential

- Static potential

a) One gluon exchange potential (Coulomb-like) reduces to

$$V_{\text{Coul}}(r) = -\frac{4}{3} \frac{\alpha_s}{r}$$

with the running QCD coupling constant (one-loop)

$$\alpha_s(\mu) = \frac{12\pi}{(33 - 2n_f) \ln(\mu^2/\Lambda^2)}$$

$n_f$  - number of flavours with masses below  $\mu$

$\Lambda \sim \Lambda_{\text{QCD}} \sim 200$  MeV

b) **Confining interaction** (string?)

$$V_{\text{conf}}(r) = Ar + B$$

with string tension  $A \sim 0.18 \text{ GeV}^2$

Such form of static potential is supported by lattice QCD calculations.

All phenomenologically successful static potentials coincide in the distance region  $0.2 \text{ fm} - 1.5 \text{ fm}$

**Static (nonrelativistic) potential** (Cornell)

$$V_{\text{static}}(r) = -\frac{4\alpha_s}{3r} + Ar + B$$

- Relativistic contributions to the potential

$$\begin{array}{ll} b \text{ quark} & \langle v^2/c^2 \rangle \sim 0.1 \\ c \text{ quark} & \langle v^2/c^2 \rangle \sim 0.3 \end{array}$$

- Spin-dependent terms

Lorentz structure:

a) One gluon exchange potential (OGEP)  $\longrightarrow$  Lorentz vector

OGEP is constructed using  $q_1\bar{q}_2$  scattering amplitude (as in QED)

$$\mathcal{M} = [\bar{u}_1(p'_1)\gamma^\mu u_1(p_1)][\bar{u}_2(p'_2)\gamma^\nu u_2(p_2)]D_{\mu\nu}(\mathbf{k})$$

$D_{\mu\nu}(\mathbf{k})$  - gluon propagator

$u(p)$  - Dirac spinor

b) **Confining potential**  $\longrightarrow$  Lorentz scalar, vector or mixture of scalar and vector

For the confining potential

$$\mathcal{M} = \bar{u}_1(p'_1)\bar{u}_2(p'_2)V_{\text{conf}}(\mathbf{k})u_1(p_1)u_2(p_2)$$

where

$$V_{\text{conf}}(\mathbf{k}) = V_{\text{conf}}^S(\mathbf{k}) + V_{\text{conf}}^V(\mathbf{k})\Gamma_1^\mu\Gamma_{2;\mu}$$

$\Gamma_\mu(\mathbf{k})$  - effective long-range vertex with **Pauli term**:

$$\Gamma_\mu(\mathbf{k}) = \gamma_\mu + \frac{i\kappa}{2m}\sigma_{\mu\nu}k^\nu,$$

$\kappa$  - anomalous chromomagnetic moment of quark

$$V_{\text{conf}}^S(\mathbf{k}) = \varepsilon V_{\text{conf}}(\mathbf{k})$$

$$V_{\text{conf}}^V(\mathbf{k}) = (1 - \varepsilon)V_{\text{conf}}(\mathbf{k})$$

$\varepsilon$  - mixing coefficient of scalar and vector confining potentials

Spin-dependent potential up to  $v^2/c^2$  order

$$V_{\text{spin-dep}}(r) = \textcolor{blue}{a} \mathbf{L}\mathbf{S} + \textcolor{blue}{b} \left[ \frac{3}{r^2} (\mathbf{S}_1 \mathbf{r})(\mathbf{S}_2 \mathbf{r}) - \mathbf{S}_1 \mathbf{S}_2 \right] + \textcolor{blue}{c} \mathbf{S}_1 \mathbf{S}_2 + \textcolor{blue}{d} \mathbf{L}(\mathbf{S}_1 - \mathbf{S}_2)$$

$$\mathbf{S} = \mathbf{S}_1 + \mathbf{S}_2$$

spin-orbit term

$$a = \frac{1}{4} \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right) \left( \frac{4\alpha_s}{3r^3} - \frac{A}{r} \right) + \frac{1}{m_1 m_2} \frac{4\alpha_s}{3r^3} + \left( \frac{1}{m_1} + \frac{1}{m_2} \right)^2 (1 + \kappa)(1 - \varepsilon) \frac{A}{r}$$

tensor term

$$b = \frac{1}{3m_1 m_2} \left( \frac{4\alpha_s}{3r^3} + (1 + \kappa)^2 (1 - \varepsilon) \frac{A}{r} \right)$$

spin-spin term

$$c = \frac{4}{3m_1 m_2} \left( \frac{8\pi\alpha_s}{3} \delta^3(r) + (1 + \kappa)^2 (1 - \varepsilon) \frac{A}{r} \right)$$

Charmonium  $1P$  levels ( $n_r^{2S+1}L_J$ )

Center of gravity of  ${}^3P_J$  states:

$$\bar{M}(\chi_{cJ}) = \frac{5M(\chi_{c2}) + 3M(\chi_{c1}) + M(\chi_{c0})}{9}$$

( $h_c = {}^1P_1$ )

$$M(h_c) - \bar{M}(\chi_{cJ}) \approx -\langle c \rangle = -\frac{4(1 + \kappa)^2(1 - \varepsilon)}{3m_1m_2} \left\langle \frac{A}{r} \right\rangle$$

Experiment:

$$M(h_c) - \bar{M}(\chi_{cJ}) = -0.05 \pm 0.19 \pm 0.16 \text{ MeV}$$

$$\implies (1 + \kappa)^2(1 - \varepsilon) = 0$$

$$\left. \begin{array}{l} (1 - \varepsilon) = 0 \\ \varepsilon = 1 \end{array} \right\} \implies \text{scalar confinement}$$

$$\left. \begin{array}{l} (1 + \kappa) = 0 \\ \kappa = -1 \end{array} \right\} \implies \text{mixture of scalar and vector confining potentials} \quad (\text{our choice!})$$

vanishing long-range chromomagnetic interaction !

(In agreement with the flux tube model and recent lattice QCD calculations)

- Heavy baryons

3-body problem (more complicated)

- Nonrelativistic

$$T = \sum_{i=1}^3 \frac{\mathbf{p}_i^2}{2m_i}$$

- Static potential

$$V = - \sum_{i < j} \frac{2\alpha_s}{3r_{ij}} + V_{\text{conf}}$$

- Confining potential

a)  $\Delta$ -type (pair interactions between quarks)

$$V_{\text{conf}}^\Delta = \sum_{i < j} \frac{1}{2} A r_{ij}$$

b)  $Y$ -type

$$V_{\text{conf}}^Y = A L_{\min}$$

$L_{\min}$  - the minimal length corresponding to the  $Y$ -shaped string configuration

- Spin-dependent terms:

- Spin-spin interaction

$$V_{ij}^{\text{hyp}} = \frac{16\pi\alpha_s}{3m_i m_j} \delta(r_{ij}) \mathbf{S}_i \mathbf{S}_j$$

- Spin-orbit (**LS**) and tensor terms are often neglected

- In most models main parameters (quark masses, parameters of quark interaction potential . . . ) have different values in meson and baryon sectors

- Main methods of the approximate solution of the bound state equation:

- variational approach
  - hyperradial approximation in hyperspherical formalism
  - approximate numerical solution of Faddeev type equation

- Quark-diquark picture:
  - Baryons with one heavy quark —→ heavy-quark–light-diquark picture
  - Baryons with two heavy quarks (doubly heavy) —→ light-quark–heavy-diquark picture

Three-body calculation —→ two-step two-body calculations

First step: calculation of diquark properties (masses, wave functions, diquark-gluon form factors)

Second step: calculation of masses and wave functions of baryons as the bound states of the diquark and quark

Diquark is a composite system with total spin  $S = 0, 1$ :

- diquark is not point-like: Its interaction with gluons is smeared by the form factor expressed through the overlap integral of diquark wave functions

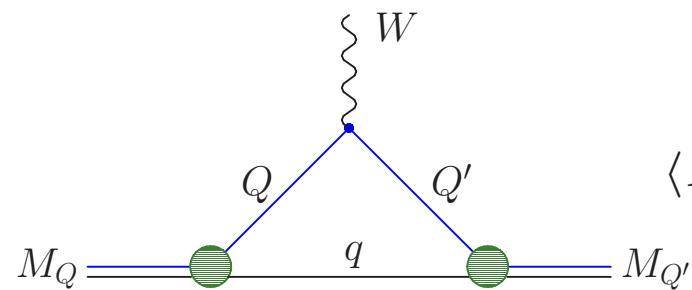

Pauli principle for ground state diquarks:

- $(qq')$  diquark can have  $S = 0, 1$  (scalar  $[q, q']$ , axial vector  $\{q, q'\}$ )
- $(qq)$  diquarks can have only  $S = 1$  (axial vector  $\{q, q\}$ )

## – Decays of heavy hadrons

- Decay widths are significantly more sensitive to the details of the quark interaction potential and relativistic corrections to the matrix elements than mass spectra
- Decay amplitudes are calculated as convolution of quark diagrams with the wave functions of initial and final hadrons

### Semileptonic decays of heavy mesons

$$\langle M_{Q'} | J_\mu(0) | M_Q \rangle = \int \frac{d^3 p d^3 q}{(2\pi)^6} \bar{\Psi}_{M_{Q'}} \mathbf{P}(\mathbf{p}) \Gamma_\mu(\mathbf{p}, \mathbf{q}) \Psi_{M_Q} \mathbf{Q}(\mathbf{q})$$

- Usually decay form factors are calculated at some kinematical point (minimal or maximal recoil of the final meson) and then extrapolated to the whole kinematical range using some ansatz (pole, Gaussian etc.). Only in some relativistic quark models form factors are explicitly calculated for all values of momentum transfer
- **Important:** Weak decay matrix elements should satisfy all constraints of heavy quark symmetry (not automatically fulfilled in models)
- For relativistic calculations it is necessary to account for the relativistic transformations of hadron wave functions from the rest to moving reference frame

## 2. RELATIVISTIC QUARK MODEL

Quasipotential equation of Schrödinger type:

$$\left( \frac{b^2(M)}{2\mu_R} - \frac{\mathbf{p}^2}{2\mu_R} \right) \Psi_M(\mathbf{p}) = \int \frac{d^3q}{(2\pi)^3} V(\mathbf{p}, \mathbf{q}; M) \Psi_M(\mathbf{q})$$

$\mathbf{p}$  - relative momentum of quarks (diquarks)

$M$  - bound state mass ( $M = E_1 + E_2$ )

$\mu_R$  - relativistic reduced mass:

$$\mu_R = \frac{E_1 E_2}{E_1 + E_2} = \frac{M^4 - (m_1^2 - m_2^2)^2}{4M^3}$$

$b(M)$  - on-mass-shell relative momentum in cms:

$$b^2(M) = \frac{[M^2 - (m_1 + m_2)^2][M^2 - (m_1 - m_2)^2]}{4M^2}$$

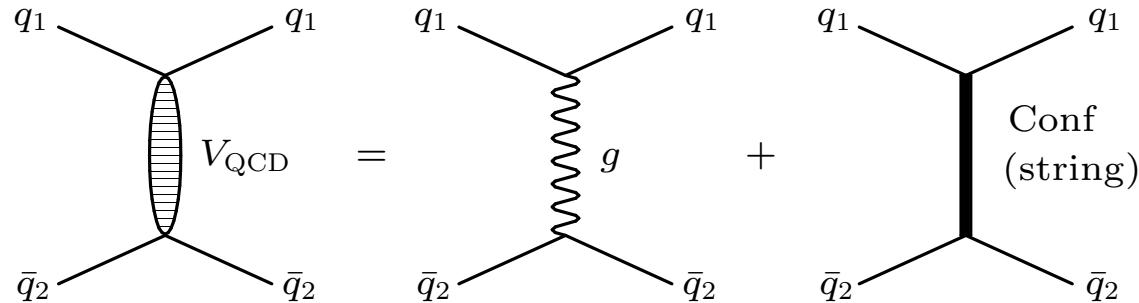

$E_{1,2}$  - center of mass energies:

$$E_1 = \frac{M^2 - m_2^2 + m_1^2}{2M}, \quad E_2 = \frac{M^2 - m_1^2 + m_2^2}{2M}$$

- Heavy mesons

- $q\bar{q}$  quasipotential

(Constructed with the help of off-mass-shell scattering amplitude projected onto positive-energy states)

$$V(\mathbf{p}', \mathbf{p}; M) = \bar{u}_1(p') \bar{u}_2(-p') \left\{ \frac{4}{3} \alpha_S D_{\mu\nu}(\mathbf{k}) \gamma_1^\mu \gamma_2^\nu + V_{\text{conf}}^V(\mathbf{k}) \Gamma_1^\mu \Gamma_{2;\mu} + V_{\text{conf}}^S(\mathbf{k}) \right\} u_1(p) u_2(-p)$$

$$\mathbf{k} = \mathbf{p}' - \mathbf{p}$$

$D_{\mu\nu}(\mathbf{k})$  - (perturbative) gluon propagator

$\Gamma_\mu(\mathbf{k})$  - effective long-range vertex with Pauli term:

$$\Gamma_\mu(\mathbf{k}) = \gamma_\mu + \frac{i\kappa}{2m} \sigma_{\mu\nu} k^\nu,$$

$\kappa$  - anomalous chromomagnetic moment of quark,

## Model parameters (9)

Parameters  $A$ ,  $B$ ,  $\kappa$ ,  $\varepsilon$  and constituent quark masses are fixed from analysis of meson masses and radiative decays:

$\varepsilon = -1$  from heavy quarkonium radiative decays ( $J/\psi \rightarrow \eta_c + \gamma$ ) and HQET

$\kappa = -1$  from fine splitting of heavy quarkonium  $^3P_J$  states and HQET

$(1 + \kappa) = 0 \implies$  vanishing long-range chromomagnetic interaction !

### Quasipotential parameters:

$$A = 0.18 \text{ GeV}^2, \quad B = -0.30 \text{ GeV},$$

$$\Lambda = 0.169 \text{ GeV}$$

### Quark masses:

$$m_b = 4.88 \text{ GeV} \quad m_s = 0.50 \text{ GeV}$$

$$m_c = 1.55 \text{ GeV} \quad m_{u,d} = 0.33 \text{ GeV}$$

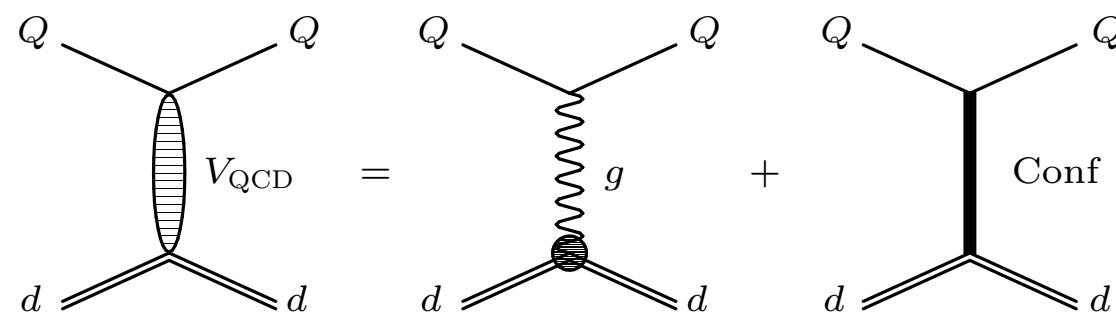

- Heavy baryons in quark-diquark picture

$(qq)$ -interaction:

$$V_{qq} = \frac{1}{2} V_{q\bar{q}}$$

$(dQ)$ -interaction:

$$d = (qq')$$

### 3. SELECTED CQM PREDICTIONS

–  $B_c$  meson

Table 1:  $B_c$  mass spectrum (in MeV).

## Semileptonic decays of $B_c$ mesons

- $B_c$  is the only meson consisting from two heavy quarks that decays only by weak interactions
- decays of both heavy quarks give compatible contributions to the total decay rate:  
 $c$  quark decays  $\sim 70\%$   
 $b$  quark decays  $\sim 20\%$   
weak annihilation  $\sim 10\%$

Table 2: Semileptonic decay rates  $\Gamma$  (in  $10^{-15}$  GeV) of  $B_c$  mesons.

## 4. SUMMARY

- Although CQM is based on assumptions and approximations that cannot be directly derived from QCD it provides a useful tool for studying the properties of hadrons
- The uncertainties of calculations can be reliably estimated only in the framework of the model itself. The accuracy of the quark model approximations is unknown
- At present for many properties of hadrons (such as excited hadron states, multiquark states . . . ) it is the only tool that can give numerical predictions
- Many predictions of quark models were confirmed by experiment

“My conclusion is that if you want to know the mass of a particle and if you have little time (in years!) and little money you should forget all your prejudices and use potential models. This is, in fact, even true to a large extent for systems containing light quarks, which is still more mysterious.”
