# Outline

## NMSSM and light pseudoscalars

- The Higgs sector of the NMSSM
- Scanning the NMSSM
- Scan results

## LHC analyses

- Cuts and backgrounds
- Results  $H_1 = H_{SM}$
- Results  $H_2 = H_{SM}$

## Future prospects and conclusions

- Summary of results
- Shortcomings and possible improvements
- Conclusions

Conclusions

## The light pseudoscalar

$m_{A_1}$  is essentially a free parameter in the theory.

Many searches  $m_{A_1} < 10$  GeV.

0805.3505, 1101.1137, 1206.6326, 1210.7619.

We focus mostly on  $10 < m_{A_1} < m_{H_{SM}}$ .

Hard to detect directly: no VBF nor Higgstrahlung, gluon fusion small. Maybe associated  $b\bar{b}A_1$  production? 1105.4191

Our studies shows no hope there either.

We must then rely on decays from heavier particles. Our focus is  $H \rightarrow A_1 A_1$  and  $H \rightarrow A_1 Z$ .

## The SM-like Higgs mass in the NMSSM

The extra scalar gives an additional contribution to the Higgs mass

$$\lambda^2 \nu^2 \sin^2(2\beta).$$

It is also possible to have a mostly singlet like scalar lighter than  $H_{SM}$  and then the mixing gives:

$$\begin{pmatrix} M_H & m \\ m & m_S \end{pmatrix} \Rightarrow M_{H_1, H_2} = \frac{M_H - m_S}{2} \pm \sqrt{\frac{(M_H - m_S)^2}{4} + m^2}.$$

## The SM-like Higgs mass in the NMSSM

The extra scalar gives an additional contribution to the Higgs mass

$$\lambda^2 \nu^2 \sin^2(2\beta).$$

It is also possible to have a mostly singlet like scalar lighter than  $H_{\text{SM}}$  and then the mixing gives:

$$\begin{pmatrix} M_H & m \\ m & m_S \end{pmatrix} \Rightarrow M_{H_1, H_2} = \frac{M_H - m_S}{2} \pm \sqrt{\frac{(M_H - m_S)^2}{4} + m^2}.$$

## Constraints

- ▶  $122 < m_{H_{SM}} < 129$  GeV,
- ▶  $m_{A_1} \lesssim 150$  GeV,
- ▶  $\Omega_\chi h^2 < 0.131$ ,
- ▶  $\text{BR}(B_s \rightarrow \mu^+ \mu^-) = (3.2 \pm 1.35 \pm 0.32) \times 10^{-9}$ ,
- ▶  $\text{BR}(B_u \rightarrow \tau \nu) = (1.66 \pm 0.66 \pm 0.38) \times 10^{-4}$ ,
- ▶  $\text{BR}(b \rightarrow s \gamma) = (3.43 \pm 0.22 \pm 0.21) \times 10^{-4}$ .

ATLAS:  $\mu^{\gamma\gamma} = 1.57_{-0.28}^{+0.33}$ ,  $\mu^{ZZ} = 1.44_{-0.35}^{+0.40}$ .

CMS:  $\mu^{\gamma\gamma} = 1.13 \pm 0.24$ ,  $\mu^{ZZ} = 1.0 \pm 0.29$ .

## Parameter ranges

Bayesian scan using MultiNest,  
 see our paper [1409.8393](#) for details.

Parameter	Extended range	Reduced range
$m_0$ (GeV)	200 – 4000	200 – 2000
$m_{1/2}$ (GeV)	100 – 2000	100 – 1000
$A_0$ (GeV)	-5000 – 0	-3000 – 0
$\mu_{\text{eff}}$ (GeV)	100 – 2000	100 – 200
$\tan \beta$	1 – 40	1 – 6
$\lambda$	0.01 – 0.7	0.4 – 0.7
$\kappa$	0.01 – 0.7	0.01 – 0.7
$A_\lambda$ (GeV)	-2000 – 2000	-500 – 500
$A_\kappa$ (GeV)	-2000 – 2000	-500 – 500

## Scan results $H_1 = H_{SM}$

No points  $m_{A_1} < m_{H_1}/2$  in naturalness limit.

## Scan results $H_2 = H_{SM}$

Easier to obtain heavy enough  $H_{SM}$ .

Conclusions

## Acceptance cuts

- ▶  $|\eta| < 2.5$  for all final state objects,
- ▶  $p_T > 15$  GeV for all final state objects,
- ▶  $\Delta R \equiv \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} > 0.2$  for all  $b$ -quark pairs,
- ▶  $\Delta R > 0.4$  for all other pairs of final state objects.

## Backgrounds

Irreducible backgrounds obtained from MadGraph.

Channel	Background cross section
$b\bar{b}b\bar{b}$	3400 pb
$b\bar{b}\tau^+\tau^-$	3.1 pb
$\tau^+\tau^-\tau^+\tau^-$	5.4 fb
$b\bar{b}Z$	126 pb
$\tau^+\tau^-Z$	0.46 pb

Signal and (parton level) background  
 hadronised and clustered in Pythia.

Jet substructure methods ([0802.2470](#)) used to find “fat jets”  
 consisting of 2 b-jets.

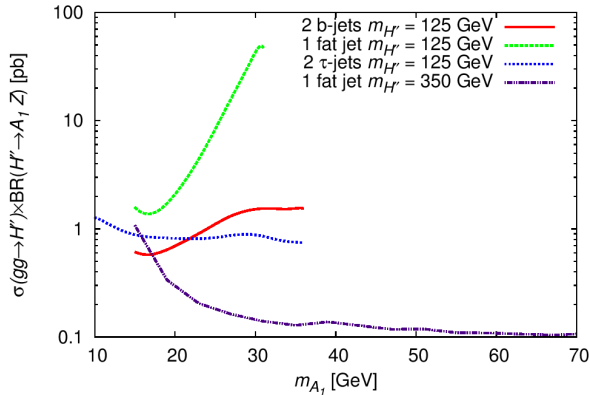

# Sensitivity $A_1 A_1$

The  $b\bar{b}\tau^+\tau^-$  channel most promising.

# Sensitivity $A_1 Z$

Most efficient for a heavier scalar.

# Sensitivity in $A_1 A_1$ channel

Some hope for detection but limited number of points.

## Sensitivity in $A_1 Z$ channel

At least HL-LHC may discover something.

# Sensitivity in $A_1 A_1$ channel

The LHC should exclude  $m_{A_1} \lesssim 60$  GeV.

## Sensitivity in $A_1 Z$ channel

Enough detectable points to motivate further study.

## Detectability ranges

Production mode	Final states	Accessibility	Range (GeV)
$b\bar{b}A_1$	$4b, 2b2\tau$	x	
$H_1 \rightarrow A_1 A_1 (H_1)$	$4b, 2b2\tau, 4\tau$	✓ 300/fb	$m_{A_1} < 63$
$H_1 \rightarrow A_1 A_1 (H_2)$	$4b, 2b2\tau, 4\tau$	✓ 30/fb	$m_{A_1} < 60$
$H_1 \rightarrow A_1 Z$	$2b2l, 2\tau 2l$	x	
$H_2 \rightarrow A_1 A_1 (H_1)$	$4b, 2b2\tau, 4\tau$	✓ 300/fb	$60 < m_{A_1} < 80$
$H_2 \rightarrow A_1 A_1 (H_2)$	$4b, 2b2\tau, 4\tau$	✓ 30/fb	$m_{A_1} < 63$
$H_2 \rightarrow A_1 Z$	$2b2l, 2\tau 2l$	x	
$H_3 \rightarrow A_1 A_1$	$4b, 2b2\tau, 4\tau$	x	
$H_3 \rightarrow A_1 Z$	$2b2l, 2\tau 2l$	✓ 300/fb	$60 < m_{A_1} < 120$

## Some points for future studies

- ▶ The “tagging” is done from MC truth with average efficiencies added as factors on  $\sigma$ .
- ▶ Only irreducible backgrounds included, e.g. no  $t\bar{t}$ .
- ▶ No detector effects nor triggering are included.
- ▶ Cuts are not optimised. Especially for  $H_3 \rightarrow A_1 Z$ , harder cuts may improve sensitivity.
- ▶ Maybe improved jet substructure technics.
- ▶ Improved tau reconstruction, e.g. collinear approximation.
- ▶ Fitting to kinematic distributions, rather than just using  $S/\sqrt{B}$  per bin.

## Some points for future studies

- ▶ Maybe improved jet substructure technics.
- ▶ Improved tau reconstruction, e.g. collinear approximation.
- ▶ Fitting to kinematic distributions, rather than just using  $S/\sqrt{B}$  per bin.

# Conclusions

- ▶ Due to the extra singlet, the NMSSM may feature a very light pseudoscalar.
- ▶ In the most natural region (large  $\lambda$ , small  $\tan \beta$ ) the LHC will practically exclude  $m_{A_1} < 60$  GeV.
- ▶ For somewhat heavier pseudoscalars,  $H_3 \rightarrow A_1 Z$  is a very interesting channel.
