

## 1.) Reminder:

equation of motion

$$
x^{\prime \prime}+K(s)^{*} x=0 \quad K=-k+1 / \rho^{2}
$$

single particle trajectory considering both planes

$$
\left(\begin{array}{c}
x(s) \\
x^{\prime}(s) \\
y(s) \\
y^{\prime}(s)
\end{array}\right)=M *\left(\begin{array}{c}
x\left(s_{0}\right) \\
x^{\prime}\left(s_{0}\right) \\
y\left(s_{0}\right) \\
y^{\prime}\left(s_{0}\right)
\end{array}\right)
$$

e.g. matrix for a quadrupole lens:

$$
M_{f o c}=\left(\begin{array}{cccc}
\cos (\sqrt{|k|} s & \frac{1}{\sqrt{|k|}} \sin (\sqrt{|k|} s & 0 & 0 \\
-\sqrt{|k|} \sin (\sqrt{|k|} s & \cos (\sqrt{|k|} s & 0 & 0 \\
0 & 0 & \cosh (\sqrt{|k|} s & \frac{1}{\sqrt{|k|}} \sinh (\sqrt{|k|} s \\
0 & 0 & \sqrt{|k|} \sinh (\sqrt{|k|} s & \cosh (\sqrt{|k|} s
\end{array}\right)=\left(\begin{array}{cccc}
C_{x} & S_{x} & 0 & 0 \\
C_{x}^{\prime} & S_{x}^{\prime} & 0 & 0 \\
0 & 0 & C_{y} & S_{y} \\
0 & 0 & C_{y}^{\prime} & S_{y}^{\prime}
\end{array}\right)
$$

## 2.) Dispersion

## momentum error:

$$
\Delta p / p^{\neq 0} \quad x^{\prime \prime}+x\left(\frac{1}{\rho^{2}}-k\right)=\frac{\Delta p}{p} \cdot \frac{1}{\rho}
$$

general solution:

$$
\begin{aligned}
& x(s)=x_{h}(s)+x_{i}(s) \\
& D(s)=\frac{x_{i}(s)}{\Delta p / p} \\
& \left(\begin{array}{c}
x \\
x^{\prime} \\
\frac{\Delta p}{p}
\end{array}\right)_{S}=\left(\begin{array}{ccc}
C & S & D \\
C^{\prime} & S^{\prime} & D^{\prime} \\
0 & 0 & 1
\end{array}\right) *\left(\begin{array}{c}
x \\
x^{\prime} \\
\frac{\Delta p}{p}
\end{array}\right)_{0}
\end{aligned}
$$

## Dispersion

the dispersion function $\mathrm{D}(\mathrm{s})$ is (...obviously) defined by the focusing properties of the lattice and is given by:

$$
D(s)=S(s) * \frac{1}{\rho(\widetilde{s})} C(\widetilde{s}) d \widetilde{s}-C(s) * \frac{1}{\rho(\widetilde{s})} S(\widetilde{s}) d \widetilde{s}
$$

! weak dipoles $\rightarrow$ large bending radius $\rightarrow$ small dispersion

Example: Drift

$$
\begin{aligned}
M_{D}=\left(\begin{array}{ll}
1 & 1 \\
0 & 1
\end{array}\right) & D(s)=S(s) * \underbrace{\frac{1}{\rho(\widetilde{s})}}_{=0} C(\widetilde{s}) d \widetilde{s}-C(s) * \underbrace{\int \frac{1}{\rho(\widetilde{s})}}_{=0} S(\widetilde{s}) d \widetilde{s} \\
\rightarrow M_{D}=\left(\begin{array}{lll}
1 & 1 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right) & \begin{array}{l}
\text {...in similar way for quadrupole matrices, } \\
\text { !!! in a quite different way for dipole matrix (see appendix) }
\end{array}
\end{aligned}
$$

## Dispersion in a FoDo Cell:

!! we have now introduced dipole magnets in the FoDo:
$\rightarrow$ we still neglect the weak focusing contribution $1 / \rho^{2}$
$\rightarrow$ but take into account $1 / \rho$ for the dispersion effect assume: length of the dipole $=1_{D}$

Calculate the matrix of the FoDo half cell in thin lens approximation: in analogy to the derivations of $\hat{\beta}, \stackrel{\vee}{\beta}$

* thin lens approximation: $\quad f=\frac{1}{k \mathrm{l}_{Q}} \gg \mathrm{l}_{Q}$
* length of quad negligible $\quad l_{Q} \approx 0, \rightarrow l_{D}=\frac{1}{2} L$
* start at half quadrupole $\quad \frac{1}{\tilde{f}}=\frac{1}{2 f}$

Matrix of the half cell

$$
\begin{aligned}
& M_{\text {Halfeell }}= M_{\frac{Q D}{2}} * M_{B} * M_{\frac{Q F}{2}} \\
& M_{\text {Halfeell }}=\left(\begin{array}{cc}
1 & 0 \\
\frac{1}{\tilde{f}} & 1
\end{array}\right) *\left(\begin{array}{cc}
1 & l \\
0 & 1
\end{array}\right) *\left(\begin{array}{cc}
1 & 0 \\
\frac{-1}{\tilde{f}} & 1
\end{array}\right) \\
& M_{\text {Halfell }}=\left(\begin{array}{cc}
C & S \\
C^{\prime} & S^{\prime}
\end{array}\right)=\left(\begin{array}{cc}
1-\frac{1}{\tilde{f}} & 1 \\
\frac{-1}{\tilde{f}} & 1+\frac{1}{\tilde{f}}
\end{array}\right)
\end{aligned}
$$

calculate the dispersion terms $D, D^{\prime}$ from the matrix elements

$$
D(s)=S(s) * \int \frac{1}{\rho(\widetilde{s})} C(\widetilde{s}) d \widetilde{s}-C(s) * \int \frac{1}{\rho(\widetilde{s})} S(\widetilde{s}) d \widetilde{s}
$$

$$
D(\ell)=\underbrace{\ell *}_{\mathbf{S}(\mathbf{s})} \frac{1}{\rho} \int_{\mathbf{C}(\mathbf{s})}^{\int_{0}^{\ell}}(\underbrace{\left(1-\frac{s}{\tilde{f}}\right)}_{\mathbf{C}(\mathbf{s})} d s \underbrace{-\left(1-\frac{\ell}{\tilde{f}}\right.}_{\mathbf{S}(\mathbf{s})})
$$

$$
D(\ell)=\frac{\ell}{\rho}\left(\ell-\frac{\ell^{2}}{2 \tilde{f}}\right)-\left(1-\frac{\ell}{\tilde{f}}\right) * \frac{1}{\rho} * \frac{\ell^{2}}{2}=\frac{\ell^{2}}{\rho}-\frac{\ell^{3}}{2 \tilde{f} \rho}-\frac{\ell^{2}}{2 \rho}+\frac{\ell^{3}}{2 \tilde{f} \rho}
$$

and we get the complete matrix including the dispersion terms $D, D^{\prime}$

$$
M_{\text {haffell }}=\left(\begin{array}{ccc}
C & S & D \\
C^{\prime} & S^{\prime} & D^{\prime} \\
0 & 0 & 1
\end{array}\right)=\left(\begin{array}{ccc}
1-\frac{\ell}{\tilde{f}} & \ell & \frac{\ell^{2}}{2 \rho} \\
\frac{-\ell}{\tilde{f}^{2}} & 1+\frac{\ell}{\tilde{f}} & \frac{\ell}{\rho}\left(1+\frac{\ell}{2 \tilde{f}}\right) \\
0 & 0 & 1
\end{array}\right)
$$

boundary conditions for the transfer from the center of the foc. to the center of the defoc. quadrupole

$$
\left(\begin{array}{c}
v \\
D \\
0 \\
1
\end{array}\right)=M_{1 / 2} *\left(\begin{array}{c}
\hat{D} \\
0 \\
1
\end{array}\right)
$$

## Dispersion in a FoDo Cell

$$
\rightarrow \quad \breve{D}=\hat{D}\left(1-\frac{\ell}{\tilde{f}}\right)+\frac{\ell^{2}}{2 \rho}
$$

$\rightarrow \quad 0=-\frac{\ell}{\tilde{f}^{2}} * \hat{D}+\frac{\ell}{\rho}\left(1+\frac{\ell}{2 \tilde{f}}\right)$

$$
\hat{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1+\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}} \quad \stackrel{\vee}{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1-\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}}
$$

where $\psi_{\text {cell }}$ denotes the phase advance of the full cell and $l / f=\sin (\psi / 2)$

## Nota bene:

! small dispersion needs strong focusing
$\rightarrow$ large phase advance
$!!\leftrightarrow$ there is an optimum phase for small $\beta$
!!! ...do you remember the stability criterion? $1 / 2$ trace $=\cos \psi \leftrightarrow \psi<180^{\circ}$
!!!! ... life is not easy

## 3.) Lattice Design: Insertions

... the most complicated one: the drift space

Question to the auditorium: what will happen to the beam parameters $\alpha, \beta, \gamma$ if we stop focusing for a while ...?

$$
\left(\begin{array}{l}
\beta \\
\alpha \\
\gamma
\end{array}\right)_{S}=\left(\begin{array}{ccc}
C^{2} & -2 S C & S^{2} \\
-C C^{\prime} & S C^{\prime}+S^{\prime} C & -S S^{\prime} \\
C^{\prime 2} & -2 S^{\prime} C^{\prime} & S^{\prime 2}
\end{array}\right) *\left(\begin{array}{l}
\beta \\
\alpha \\
\gamma
\end{array}\right)_{0}
$$

transfer matrix for a drift: $\quad M=\left(\begin{array}{cc}C & S \\ C^{\prime} & S^{\prime}\end{array}\right)=\left(\begin{array}{cc}1 & S \\ 0 & 1\end{array}\right)$

$$
\begin{aligned}
& \beta(s)=\beta_{0}-2 \alpha_{0} s+\gamma_{0} s^{2} \\
& \alpha(s)=\alpha_{0}-\gamma_{0} s \\
& \gamma(s)=\gamma_{0}
\end{aligned}
$$

„0" refers to the position of the last lattice element
,"" refers to the position in the drift
location of the waist:

given the initial conditions $\alpha_{0}, \beta_{0, \gamma_{0}}$ : where is the point of smallest beam dimension in the drift ... or at which location occurs the beam waist?
beam waist:

$$
\alpha(s)=0 \quad \rightarrow \quad \alpha_{0}=\gamma_{0} *_{S}
$$

$$
\mathrm{l}=\frac{\alpha_{0}}{\gamma_{0}}
$$

beam size at that position:

$$
\left.\begin{array}{l}
\gamma(\mathrm{l})=\gamma_{0} \\
\alpha(\mathrm{l})=0
\end{array}\right\} \rightarrow \gamma(l)=\frac{1+\alpha^{2}(\mathrm{l})}{\beta(\mathrm{l})}=\frac{1}{\beta(\mathrm{l})}
$$

$$
\beta(\mathrm{l})=1 / \gamma_{0}
$$

## $\beta$-Function in a Drift:

let 's assume we are at a symmetry point in the center of a drift.

$$
\beta(s)=\beta_{0}-2 \alpha_{0} s+\gamma_{0} s^{2}
$$

as $\quad \alpha_{0}=0, \quad \rightarrow \quad \gamma_{0}=\frac{1+\alpha_{0}{ }^{2}}{\beta_{0}}=\frac{1}{\beta_{0}}$
and we get for the $\beta$ function in the neighborhood of the symmetry point

$$
\beta(s)=\beta_{0}+\frac{s^{2}}{\beta_{0}}
$$

## Nota bene:

1.) this is very bad !!!
2.) this is a direct consequence of the conservation of phase space density (... in our words: $\varepsilon=$ const) ... and there is no way out.
3.) Thank you, Mr. Liouville !!!

Joseph Liouville, 1809-1882

## Alternative description: The Beam Matrix

„Once more unto the breach dear friends:"
Transformation of Twiss parameters
just because it is mathematical more elegant ...
let 's define a beam matrix: $\quad B_{0}=\left(\begin{array}{cc}\beta_{0} & -\alpha_{0} \\ \alpha_{0} & \gamma_{0}\end{array}\right)$
and a orbit vector: $\quad X_{0}=\binom{x_{0}}{x_{0}^{\prime}}, \quad X^{T}=\left(\begin{array}{ll}x_{0}, & x_{0}^{\prime}\end{array}\right)$

the product $X_{0}{ }^{T} * B_{0}^{-1} * X_{0}=\left(x_{0}, x_{0}^{\prime}\right) *\left(\begin{array}{cc}\gamma_{0} & \alpha_{0} \\ \alpha_{0} & \beta_{0}\end{array}\right) *\binom{x_{0}}{x^{\prime}{ }_{0}}=\gamma_{0} x_{0}^{2}+2 \alpha_{0} x_{0} x_{0}^{\prime}+\beta_{0} x_{0}^{\prime 2}=\varepsilon$ ... is constant
transformation of the orbit vector: $\quad X_{1}=M^{*} X_{0}$
and so we get: $\varepsilon=X_{0}{ }^{T} * B_{0}^{-1} * X_{0}=X_{0}^{T} \underline{M^{T}\left(M^{T}\right)^{-1} B_{0}^{-1} \underline{M^{-1} M} X_{0}, ~}$

$$
=X_{0}^{T} M^{T}\left\{\left(M^{T}\right)^{-1} B_{0}^{-1} M^{-1}\right\} M X_{0}
$$

## Transformation of Twiss parameters

and using $A^{T} B^{T}=(B A)^{T}$ and $A^{-1} B^{-1}=(B A)^{-1}$

$$
\begin{aligned}
& \varepsilon=X_{0}^{T} M^{T}\left\{\left(M^{T}\right)^{-1}\left(M B_{0}\right)^{-1}\right\} M X_{0} \\
&=X_{0}^{T} M^{T}\left\{M B_{0} M^{T}\right\}^{-1} M X_{0} \\
&=\underbrace{\left(M X_{0}\right)^{T}\left\{M B_{0} M^{T}\right\}^{-1} \underbrace{M X_{0}}} \begin{aligned}
& \left.\left.=X_{1}^{T} M_{0} M^{T}\right\}\right)^{-1} X_{1}
\end{aligned} \\
& \text { w already that } \\
& \varepsilon=\text { const }=X_{0}{ }^{T} * B_{0}^{-1} * X_{0}=X_{1}^{T} * B_{1}^{-1} * X_{1}
\end{aligned}
$$

but we know already that
and in the end and after all we learn that ...
in full equivalence to ...

$$
B_{1}=\left(\begin{array}{cc}
\beta_{1} & -\alpha_{1} \\
\alpha_{1} & \gamma_{1}
\end{array}\right)=M * B_{0} * M^{T} \quad\left(\begin{array}{c}
\beta \\
\alpha \\
\gamma
\end{array}\right)_{s 2}=\left(\begin{array}{ccc}
m_{11}^{2} & -2 m_{11} m_{12} & m_{12}^{2} \\
-m_{11} m_{21} & m_{12} m_{21}+m_{22} m_{11} & -m_{12} m_{22} \\
m_{12}^{2} & -2 m_{22} m_{21} & m_{22}^{2}
\end{array}\right) *\left(\begin{array}{l}
\beta \\
\alpha \\
\gamma
\end{array}\right)_{s 1}
$$

Transformation of Twiss parameters

Example again the drift space

... starting from $\boldsymbol{a}_{0}=0$

$$
\begin{aligned}
M & =\left(\begin{array}{ll}
1 & s \\
0 & 1
\end{array}\right) \\
B_{0} & =\left(\begin{array}{cc}
\beta_{0} & -\alpha_{0} \\
-\alpha_{0} & \gamma_{0}
\end{array}\right)=\left(\begin{array}{cc}
\beta_{0} & 0 \\
0 & 1 / \beta_{0}
\end{array}\right)
\end{aligned}
$$

Beam parameters after the drift: $\quad B_{1}=M B_{0} M^{T}=\left(\begin{array}{ll}1 & s \\ 0 & 1\end{array}\right) *\left(\begin{array}{cc}\beta_{0} & 0 \\ 0 & 1 / \beta_{0}\end{array}\right) *\left(\begin{array}{ll}1 & 0 \\ s & 1\end{array}\right)$

$$
=\left(\begin{array}{cc}
\beta_{0}+\frac{s^{2}}{\beta_{0}} & \frac{s}{\beta_{0}} \\
\frac{s}{\beta_{0}} & \frac{1}{\beta_{0}}
\end{array}\right) \longrightarrow \quad \beta_{1}=\beta_{0}+\frac{s^{2}}{\beta_{0}}
$$

## A bit more in detail: $\beta$-Function in a Drift

If we cannot fight against Liouvuille theorem ... at least we can optimise Optimisation of the beam dimension:

$$
\beta(\mathrm{l})=\beta_{0}+\frac{\mathrm{l}^{2}}{\beta_{0}}
$$

Find the $\beta$ at the center of the drift that leads to the lowest maximum $\beta$ at the end:

$$
\frac{d \hat{\beta}}{d \beta_{0}}=1-\frac{\mathrm{l}^{2}}{\beta_{0}^{2}}=0
$$

$$
\rightarrow \beta_{0}=l
$$

$$
\rightarrow \hat{\beta}=2 \beta_{0}
$$

If we choose $\beta_{0}=\ell$ we get the smallest $\beta$ at the end of the drift and the maximum $\beta$ is just twice the distance $\ell$
... clearly there is an But: ... unfortunately ... in general
high energy detectors that are installed in that drift spaces

## Luminosity \& Minibeta Insertion

$$
R=L * \Sigma_{\text {react }}
$$

$$
L=\frac{1}{4 \pi e^{2} f_{0} n_{b}} * \frac{I_{p 1} I_{p^{2}}}{\sigma_{x} \sigma_{y}}
$$

Example: Luminosity run at LHC

$$
\begin{array}{ll}
\boldsymbol{\beta}_{x, y}=0.55 \boldsymbol{m} & \boldsymbol{f}_{0}=11.245 \mathbf{k H z} \\
\boldsymbol{\varepsilon}_{x, y}=5 * 10^{-10} \mathrm{rad} \boldsymbol{m} & \boldsymbol{n}_{b}=2808 \\
\boldsymbol{\sigma}_{x, y}=17 \boldsymbol{\mu m} & \\
\boldsymbol{I}_{p}=584 \boldsymbol{m} \boldsymbol{A} &
\end{array}
$$

$$
L=1.0 * 10^{34} \mathrm{l} / \mathrm{cm}^{2} \boldsymbol{s}
$$

production rate of events is determined by the cross section $\Sigma_{\text {react }}$ and the luminosity that is given by the design of the accelerator

## Mini- $\beta$ Insertions: Betafunctions

A mini- $\beta$ insertion is always a kind of special symmetride drift space.
$\rightarrow$ greetings from Liouville

$$
\begin{aligned}
& \alpha^{*}=0 \\
& \gamma^{*}=\frac{1+\alpha^{2}}{\beta}=\frac{1}{\beta^{*}} \\
& \sigma^{\prime *}=\sqrt{\frac{\varepsilon}{\beta^{*}}}
\end{aligned}
$$

$$
\beta^{*}=\frac{\sigma^{*}}{\sigma^{\prime *}}
$$

size of $\beta$ at the second quadrupole lens (in thin lens approx):
... after some transformations and a couple of beer ...

## Mini- $\beta$ Insertions: Phase advance

By definition the phase advance is given by: $\quad \Phi(s)=\int \frac{1}{\beta(s)} d s$

$$
\begin{aligned}
& \text { Now in a mini } \beta \text { insertion: } \quad \beta(s)=\beta_{0}\left(1+\frac{s^{2}}{\beta_{0}^{2}}\right) \\
& \rightarrow \Phi(s)=\frac{1}{\beta_{0}} \int_{0}^{L} \frac{1}{1+s^{2} / \beta_{0}^{2}} d s=\arctan \frac{L}{\beta_{0}}
\end{aligned}
$$

Consider the drift spaces on both sides of the IP: the phase advance of a mini $\beta$ insertion is approximately $\pi$, in other words: the tune will increase by half an integer.

## Are there any problems?

sure there are...

* large $\beta$ values at the doublet quadrupoles $\rightarrow$ large contribution to chromaticity $Q^{\prime}$... and no local correction

$$
Q^{\prime}=\frac{-1}{4 \pi} \oint K(s) \beta(s) d s
$$

* aperture of mini $\beta$ quadrupoles
limit the luminosity
beam envelope at the first mini $\beta$ quadrupole lens in the HERA proton storage ring

* field quality and magnet stability most critical at the high $\beta$ sections effect of a quad error:

$$
\Delta Q=\int_{s 0}^{s 0+l} \frac{\Delta K(s) \beta(s) d s}{4 \pi}
$$

$\rightarrow$ keep distance „s" to the first mini $\beta$ quadrupole as small as possible

## Mini- $\beta$ Insertions: some guide lines

* calculate the periodic solution in the arc
* introduce the drift space needed for the insertion device (detector ...)
* put a quadrupole doublet (triplet ?) as close as possible
* introduce additional quadrupole lenses to match the beam parameters to the values at the beginning of the arc structure
parameters to be optimised \& matched to the periodic solution: $\begin{array}{ll}\alpha_{x}, \beta_{x} \\ \alpha_{y}, \beta_{y}\end{array} \begin{aligned} & D_{x}, D_{x}^{\prime} \\ & Q_{x}, Q_{y}\end{aligned}$

8 individually powered quad magnets are needed to match the insertion ( ... at least)

## 5.) Dispersion Suppressors

There are two rules of paramount importance about dispersion:
$!$ it is nasty
!! it is not easy to get rid of it.
remember: oscillation amplitude for a particle with momentum deviation

$$
x(s)=x_{\beta}(s)+D(s) * \frac{\Delta p}{p}
$$

beam size at the IP

$$
\sigma^{*}=17 \mu m
$$

$$
\begin{array}{ll}
\text { dispersion trajectory } & \left.\begin{array}{l}
\bar{D}=1.5 m \\
\frac{\Delta p}{p} \approx 1.1 * 10^{-4}
\end{array}\right] \quad x_{D}=165 \mu \mathrm{~m}
\end{array}
$$

## Dispersion Suppressors

$$
D(s)=S(s) * \int \frac{1}{\rho(\widetilde{s})} C(\widetilde{s}) d \widetilde{s}-C(s) * \int \frac{1}{\rho(\widetilde{s})} S(\widetilde{s}) d \widetilde{s}
$$

optical functions of a FoDo cell without dipoles: $\boldsymbol{D}=0$

Remember: Dispersion in a FoDo cell including dipoles

$$
\hat{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1+\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}} \quad \breve{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1-\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}}
$$

FoDo cell including the effect of the bending magnets

## Dispersion Suppressor Schemes

1.) The straight forward one: use additional quadrupole lenses to match the optical parameters ... including the $D(s), D^{\prime}(s)$ terms

* Dispersion suppressed by 2 quadrupole lenses,
* $\beta$ and $\alpha$ restored to the values of the periodic solution by 4 additional quadrupoles

$$
\left.\begin{array}{l}
D(s), \quad D^{\prime}(s) \\
\beta_{x}(s), \alpha_{x}(s) \\
\beta_{y}(s), \alpha_{y}(s)
\end{array}\right\} \quad \rightarrow \quad \begin{aligned}
& 6 \text { additional quadrupole } \\
& \text { lenses required }
\end{aligned}
$$

## Dispersion Suppressor Quadrupole Scheme

Advantage:
! easy,
! flexible: it works for any phase advance per cell
! does not change the geometry of the storage ring,
! can be used to match between different lattice structures (i.e. phase advances)

Disadvantage:
! additional power supplies needed ( $\rightarrow$ expensive)
! requires stronger quadrupoles
! due to higher $\beta$ values: more aperture required

## 2.) The Missing Bend Dispersion Suppressor

... turn it the other way round:

$$
\text { Start with } \quad D(s)=0, \quad D^{\prime}(s)=0
$$

and create dispersion - using dipoles - in such a way, that it fits exactly the conditions at the centre of the first regular quadrupoles:

$$
D(s)=S(s)^{*} \int \frac{1}{\rho(\tilde{s})} C(\tilde{s}) d \tilde{s}-C(s)^{*} \int \frac{1}{\rho(\tilde{s})} S(\tilde{s}) d \tilde{s} \quad \rightarrow \quad \hat{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1+\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}}, \quad D^{\prime}=0
$$

at the end of the arc: add $m$ cells without

2.) The Missing Bend Dispersion Suppressor
conditions for the (missing) dipole fields:

$$
\frac{2 m+n}{2} \Phi_{C}=(2 k+1) \frac{\pi}{2}
$$

$$
\begin{aligned}
& \sin \frac{n \Phi_{C}}{2}=\frac{1}{2}, k=0,2 \ldots \text { or } \\
& \sin \frac{n \Phi_{C}}{2}=\frac{-1}{2}, k=1,3 \ldots
\end{aligned}
$$

$m=$ number of cells without dipoles followed by $n$ regular arc cells.

Example:
phase advance in the arc $\Phi_{C}=60^{\circ}$ number of suppr. cells $\quad m=1$ number of regular cells $n=1$

## 3.) The Half Bend Dispersion Suppressor

condition for vanishing dispersion: $\quad 2 * \boldsymbol{\delta}_{\text {supr }} * \sin ^{2}\left(\frac{\boldsymbol{n} \Phi_{\boldsymbol{c}}}{2}\right)=\boldsymbol{\delta}_{\text {arc }}$
so if we require

$$
\begin{align*}
& \boldsymbol{\delta}_{\text {supr }}=\frac{1}{2} * \boldsymbol{\delta}_{\text {arc }} \\
& \sin ^{2}\left(\frac{\boldsymbol{n} \Phi_{\boldsymbol{c}}}{2}\right)=1
\end{align*}
$$ $\sin ^{2}(\Phi / 2)$

$\Phi$
and equivalent for $\boldsymbol{D}^{\prime}=\mathbf{0} \quad \sin \left(\boldsymbol{n} \Phi_{c}\right)=0 \quad \boldsymbol{n} \Phi_{c}=\boldsymbol{k} * \pi, \quad \boldsymbol{k}=1,3, \ldots$

in the $n$ suppressor cells the phase advance has to accumulate to a odd multiple of $\pi$
strength of suppressor dipoles is half as strong as that of arc dipoles, $\delta_{\text {suppr }}=1 / 2 \delta_{\text {arc }}$

Example: phase advance in the arc
$\Phi_{C}=60^{\circ}$
number of suppr. cells $n=3$

TLEP: $100 \mathrm{~km}, 24$ Arcs, 12 dispersion free straight sections, half bend dispersion supprı

## 6.) Resume

1.) Dispersion in a FoDo cell:
small dispersion $\leftrightarrow$ large bending radius short cells strong focusing

$$
\hat{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1+\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}} \quad \breve{D}=\frac{\ell^{2}}{\rho} * \frac{\left(1-\frac{1}{2} \sin \frac{\psi_{\text {cell }}}{2}\right)}{\sin ^{2} \frac{\psi_{\text {cell }}}{2}}
$$

2.) Chromaticity of a cell:

$$
\begin{gathered}
\text { small Q' } \leftrightarrow \text { weak focusing } \\
\text { small } \beta
\end{gathered}
$$

$$
Q_{\text {toral }}^{\prime}=\frac{-1}{4 \pi} \oint\{K(s)-m D(s)\} \beta(s) d s
$$

3.) Position of a waist at the cell end:

$$
\alpha_{0}, \beta_{0}=\text { values at the end of the cell }
$$

$$
\mathrm{l}=\frac{\alpha_{0}}{\gamma_{0}} \quad \beta(\mathrm{l})=1 / \gamma_{0}
$$

4.) $\beta$ function in a drift

$$
\beta(s)=\beta_{0}-2 \alpha_{0} s+\gamma_{0} s^{2}
$$

## 5.) Mini $\beta$ insertion

small $\beta \leftrightarrow$ short drift space required phase advance $\approx 180^{\circ}$

## Appendix I: Dispersion

... solution of the inhomogenious equation of motion
the dispersion function is given by

$$
\begin{aligned}
& D(s)=S(s) * \int \frac{1}{\rho(\widetilde{S})} C(\widetilde{S}) d \widetilde{s}-C(s) * \int \frac{1}{\rho(\widetilde{s})} S(\widetilde{s}) d \widetilde{s} \\
& \text { proof: } \quad D^{\prime}(s)=S^{\prime}(s)^{*} \int \frac{1}{\rho(\widetilde{s})} C(\widetilde{s}) d \widetilde{s}+S(s) * \frac{C(\widetilde{s})}{\rho(\widetilde{s})}-C^{\prime}(s)^{*} \int \frac{1}{\rho(\widetilde{s})} S(\widetilde{s}) d \widetilde{s}-C(s) \frac{S(\widetilde{s})}{\rho(\widetilde{s})} \\
& D^{\prime}(s)=S^{\prime}(s)^{*} \int \frac{C}{\rho} d \widetilde{s}-C^{\prime}(s)^{*} \int \frac{S}{\rho} d \widetilde{s} \\
& D^{\prime \prime}(s)=S^{\prime \prime}(s)^{*} \int \frac{C}{\rho} d \widetilde{s}+S^{\prime} \frac{C}{\rho}-C^{\prime \prime}(s)^{*} \int \frac{S}{\rho} d \widetilde{s}-C^{\prime} \frac{S}{\rho} \\
&\left.D^{\prime \prime}(s)=S^{\prime \prime}(s)^{*} \int \frac{C}{\rho} d \widetilde{s}-C^{\prime \prime}(s)^{*}+\frac{1}{\rho}\right)\left(C S^{\prime}-S C^{\prime}\right) \\
& D^{\prime \prime}(s)=S^{\prime \prime}(s)^{*} \int \frac{C}{\rho} d \widetilde{s}-C^{\prime \prime}(s)^{*} \int \frac{S}{\rho} d \widetilde{s}+\frac{1}{\rho}
\end{aligned}
$$

now the principal trajectories $S$ and $C$ fulfill the homogeneous equation

$$
S^{\prime \prime}(s)=-K^{*} S, \quad C^{\prime \prime}(s)=-K^{*} C
$$

and so we get: $\quad D^{\prime \prime}(s)=-K * S(s) * \int \frac{C}{\rho} d \widetilde{s}+K * C(s) * \int \frac{S}{\rho} d \widetilde{s}+\frac{1}{\rho}$

$$
\begin{aligned}
& D^{\prime \prime}(s)=-K^{*} \boldsymbol{D}(s)+\frac{1}{\rho} \\
& D^{\prime \prime}(s)+K^{*} D(s)=\frac{1}{\rho}
\end{aligned}
$$

qed.

## Appendix II: Dispersion Suppressors

... the calculation of the half bend scheme in full detail (for purists only)
1.) the lattice is split into 3 parts: (Gallia divisa est in partes tres)

* periodic solution of the arc
* section of the dispersion suppressor
* FoDo cells without dispersion
periodic $\beta$, periodic dispersion D
periodic $\beta$, dispersion vanishes periodic $\beta, \mathrm{D}=\mathrm{D}^{\prime}=0$

## 2.) calculate the dispersion $D$ in the periodic part of the lattice

transfer matrix of a periodic cell:

$$
M_{0 \rightarrow S}=\left(\begin{array}{cc}
\sqrt{\frac{\beta_{S}}{\beta_{0}}}\left(\cos \phi+\alpha_{0} \sin \phi\right) & \sqrt{\beta_{S} \beta_{0}} \sin \phi \\
\frac{\left(\alpha_{0}-\alpha_{S}\right) \cos \phi-\left(1+\alpha_{0} \alpha_{S}\right) \sin \phi}{\sqrt{\beta_{S} \beta_{0}}} & \sqrt{\frac{\beta_{S}}{\beta_{0}}}\left(\cos \phi-\alpha_{S} \sin \phi\right)
\end{array}\right)
$$

for the transformation from one symmetriy point to the next (i.e. one cell) we have: $\Phi_{\mathrm{C}}=$ phase advance of the cell, $\alpha=0$ at a symmetry point. The index " $c$ " refers to the periodic solution of one cell.

$$
M_{\text {Cell }}=\left(\begin{array}{ccc}
C & S & D \\
C^{\prime} & S^{\prime} & D^{\prime} \\
0 & 0 & 1
\end{array}\right)=\left(\begin{array}{ccc}
\cos \Phi_{C} & \beta_{C} \sin \Phi_{C} & D(l) \\
\frac{-1}{\beta_{C}} \sin \Phi_{C} & \cos \Phi_{C} & D^{\prime}(l) \\
0 & 0 & 1
\end{array}\right)
$$

The matrix elements D and D ' are given by the C and S elements in the usual way:

$$
\begin{aligned}
& D(l)=S(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} C(\tilde{s}) d \tilde{s}-C(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} S(\tilde{s}) d \tilde{s} \\
& D^{\prime}(l)=S^{\prime}(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} C(\tilde{s}) d \tilde{s}-C^{\prime}(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} S(\tilde{s}) d \tilde{s}
\end{aligned}
$$

here the values $\mathrm{C}(l)$ and $\mathrm{S}(l)$ refer to the symmetry point of the cell (middle of the quadrupole) and the integral is to be taken over the dipole magnet where $\rho \neq 0$. For $\rho=$ const the integral over $C(s)$ and $S(s)$ is approximated by the values in the middle of the dipole magnet.

Transformation of $\mathrm{C}(\mathrm{s})$ from the symmetry point to the center of the dipole:

$$
C_{m}=\sqrt{\frac{\beta_{m}}{\beta_{C}}} \cos \Delta \Phi=\sqrt{\frac{\beta_{m}}{\beta_{C}}} \cos \left(\frac{\Phi_{C}}{2} \pm \varphi_{m}\right) \quad S_{m}=\beta_{m} \beta_{C} \sin \left(\frac{\Phi_{C}}{2} \pm \varphi_{m}\right)
$$

where $\beta_{\mathrm{C}}$ is the periodic $\beta$ function at the beginning and end of the cell, $\beta_{\mathrm{m}}$ its value at the middle of the dipole and $\varphi_{\mathrm{m}}$ the phase advance from the quadrupole lens to the dipole center.

Now we can solve the intergal for D and D':

$$
\begin{gathered}
D(l)=S(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} C(\tilde{s}) d \tilde{s}-C(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} S(\tilde{s}) d \tilde{s} \\
D(l)=\beta_{C} \sin \Phi_{C} * \frac{L}{\rho} * \sqrt{\frac{\beta_{m}}{\beta_{C}}} * \cos \left(\frac{\Phi_{C}}{2} \pm \varphi_{m}\right)-\cos \Phi_{C} * \frac{L}{\rho} \sqrt{\beta_{m} \beta_{C}} * \sin \left(\frac{\Phi_{C}}{2} \pm \varphi_{m}\right)
\end{gathered}
$$

$$
\begin{aligned}
D(l)=\delta \sqrt{\beta_{m} \beta_{C}}\left\{\operatorname { s i n } \Phi _ { C } \left[\cos \left(\frac{\Phi_{C}}{2}+\varphi_{m}\right)\right.\right. & \left.+\cos \left(\frac{\Phi_{C}}{2}-\varphi_{m}\right)\right]- \\
& \left.-\cos \Phi_{C}\left[\sin \left(\frac{\Phi_{C}}{2}+\varphi_{m}\right)+\sin \left(\frac{\Phi_{C}}{2}-\varphi_{m}\right)\right]\right\}
\end{aligned}
$$

I have put $\delta=\mathrm{L} / \rho$ for the strength of the dipole

$$
\begin{aligned}
& \text { remember the relations } \quad \cos x+\cos y=2 \cos \frac{x+y}{2} * \cos \frac{x-y}{2} \\
& \sin x+\sin y=2 \sin \frac{x+y}{2} * \cos \frac{x-y}{2}
\end{aligned}
$$

$$
D(l)=\delta \sqrt{\beta_{m} \beta_{C}}\left\{\sin \Phi_{C} * 2 \cos \frac{\Phi_{C}}{2} * \cos \varphi_{m}-\cos \Phi_{C} * 2 \sin \frac{\Phi_{C}}{2} * \cos \varphi_{m}\right\}
$$

$$
D(l)=2 \delta \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}\left\{\sin \Phi_{C} * \cos \frac{\Phi_{C}}{2} *-\cos \Phi_{C} * \sin \frac{\Phi_{C}}{2}\right\}
$$

$$
\begin{array}{cl}
\text { remember: } & \sin 2 x=2 \sin x * \cos x \\
& \cos 2 x=\cos ^{2} x-\sin ^{2} x \\
D(l)=2 \delta \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}\left\{2 \sin \frac{\Phi_{C}}{2} * \cos ^{2} \frac{\Phi_{C}}{2}-\left(\cos ^{2} \frac{\Phi_{C}}{2}-\sin ^{2} \frac{\Phi_{C}}{2}\right) * \sin \frac{\Phi_{C}}{2}\right\}
\end{array}
$$

$$
\begin{aligned}
& D(l)=2 \delta \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m} * \sin \frac{\Phi_{C}}{2}\left\{2 \cos ^{2} \frac{\Phi_{C}}{2}-\cos ^{2} \frac{\Phi_{C}}{2}+\sin ^{2} \frac{\Phi_{C}}{2}\right\} \\
& D(l)=2 \delta \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m} * \sin \frac{\Phi_{C}}{2}
\end{aligned}
$$

in full analogy one derives the expression for $\mathrm{D}^{\prime}$ :

$$
D^{\prime}(l)=2 \delta \sqrt{\beta_{m} / \beta_{c}} * \cos \varphi_{m} * \cos \frac{\Phi_{c}}{2}
$$

As we refer the expression for D and D ' to a periodic struture, namly a FoDo cell we require periodicity conditons:

$$
\left(\begin{array}{c}
D_{C} \\
D_{C}^{\prime} \\
1
\end{array}\right)=M_{C} *\left(\begin{array}{c}
D_{C} \\
D_{C}^{\prime} \\
1
\end{array}\right)
$$

and by symmetry: $\quad D^{\prime}{ }_{C}=0$

With these boundary conditions the Dispersion in the FoDo is determined:

$$
D_{C} * \cos \Phi_{C}+\delta \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m} * 2 \sin \frac{\Phi_{C}}{2}=D_{C}
$$

$$
\begin{equation*}
D_{C}=\delta \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m} / \sin \frac{\Phi_{C}}{2} \tag{Al}
\end{equation*}
$$

This is the value of the periodic dispersion in the cell evaluated at the position of the dipole magnets.

## 3.) Calculate the dispersion in the suppressor part:

We will now move to the second part of the dispersion suppressor: The section where ... starting from $D=D$ ' $=0$ the dispesion is generated $\ldots$ or turning it around where the Dispersion of the arc is reduced to zero.
The goal will be to generate the dispersion in this section in a way that the values of the periodic cell that have been calculated above are obtained.

The relation for $D$, generated in a cell still holds in the same way:

$$
D(l)=S(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} C(\tilde{s}) d \tilde{s}-C(l) * \int_{0}^{l} \frac{1}{\rho(\tilde{s})} S(\tilde{s}) d \tilde{s}
$$

as the dispersion is generated in a number of $n$ cells the matrix for these $n$ cells is

$$
\begin{aligned}
& M_{n}=M_{C}^{n}=\left(\begin{array}{ccc}
\cos n \Phi_{C} & \beta_{C} \sin n \Phi_{C} & D_{n} \\
\frac{-1}{\beta_{C}} \sin n \Phi_{C} & \cos n \Phi_{C} & D_{n}^{\prime} \\
0 & 0 & 1
\end{array}\right) \\
& D_{n}=\beta_{C} \sin n \Phi_{C} * \delta_{\text {sup } r} * \sum_{i=1}^{n} \cos \left(i \Phi_{C}-\frac{1}{2} \Phi_{C} \pm \varphi_{m}\right) * \sqrt{\frac{\beta_{m}}{\beta_{C}}}- \\
& -\cos n \Phi_{C} * \delta_{\text {sup } r} * \sum_{i=1}^{n} \sqrt{\beta_{m} \beta_{C}} * \sin \left(i \Phi_{C}-\frac{1}{2} \Phi_{C} \pm \varphi_{m}\right) \\
& D_{n}=\sqrt{\beta_{m} \beta_{C}} * \sin n \Phi_{C} * \delta_{\text {sup } r} * \sum_{i=1}^{n} \cos \left((2 i-1) \frac{\Phi_{C}}{2} \pm \varphi_{m}\right)-\sqrt{\beta_{m} \beta_{C}} * \delta_{\text {sup } r} * \cos n \Phi_{C} \sum_{i=1}^{n} \sin \left((2 i-1) \frac{\Phi_{C}}{2} \pm \varphi_{m}\right) \\
& \text { remember: } \quad \begin{array}{r}
\sin x+\sin y=2 \sin \frac{x+y}{2} * \cos \frac{x-y}{2} \\
\cos x+\cos y=2 \cos \frac{x+y}{2} * \cos \frac{x-y}{2} \\
D_{n}=\delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \sin n \Phi_{C} * \sum_{i=1}^{n} \cos \left((2 i-1) \frac{\Phi_{C}}{2}\right) * 2 \cos \varphi_{m}- \\
-\delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos n \Phi_{C} \sum_{i=1}^{n} \sin \left((2 i-1) \frac{\Phi_{C}}{2}\right) * 2 \cos \varphi_{m}
\end{array}
\end{aligned}
$$

$$
\begin{aligned}
& D_{n}=2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}\left\{\sum_{i=1}^{n} \cos \left((2 i-1) \frac{\Phi_{C}}{2}\right) * \sin n \Phi_{C}-\sum_{i=1}^{n} \sin \left((2 i-1) \frac{\Phi_{C}}{2}\right) * \cos n \Phi_{C}\right\} \\
& D_{n}=2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}\left\{\sin n \Phi_{C}\left\{\frac{\sin \frac{n \Phi_{C}}{2} * \cos \frac{n \Phi_{C}}{2}}{\sin \frac{\Phi_{C}}{2}}\right\}-\cos n \Phi_{C} *\left\{\frac{\sin \frac{n \Phi_{C}}{2} * \sin \frac{n \Phi_{C}}{2}}{\sin \frac{\Phi_{C}}{2}}\right\}\right\} \\
& D_{n}=\frac{2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}}\left\{\sin n \Phi_{C} * \sin \frac{n \Phi_{C}}{2} * \cos \frac{n \Phi_{C}}{2}-\cos n \Phi_{C} * \sin ^{2} \frac{n \Phi_{C}}{2}\right\}
\end{aligned}
$$

set for more convenience $x=n \Phi_{C} / 2$

$$
\begin{aligned}
& D_{n}=\frac{2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}}\left\{\sin 2 x * \sin x * \cos x-\cos 2 x * \sin ^{2} x\right\} \\
& D_{n}=\frac{2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}}\left\{2 \sin x \cos x * \cos x \sin x-\left(\cos ^{2} x-\sin ^{2} x\right) \sin ^{2} x\right\}
\end{aligned}
$$

$$
\begin{equation*}
D_{n}=\frac{2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}} * \sin ^{2} \frac{n \Phi_{C}}{2} \tag{A2}
\end{equation*}
$$

and in similar calculations:

$$
D_{n}^{\prime}=\frac{2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}} * \sin n \Phi_{C}
$$

This expression gives the dispersion generated in a certain number of $n$ cells as a function of the dipole kick $\delta$ in these cells.
At the end of the dispersion generating section the value obtained for $\mathrm{D}(\mathrm{s})$ and D '(s) has to be equal to the value of the periodic solution:
$\rightarrow$ equating (A1) and (A2) gives the conditions for the matching of the periodic dispersion in the arc to the values $\mathrm{D}=\mathrm{D}{ }^{\prime}=0$ afte the suppressor.

$$
D_{n}=\frac{2 \delta_{\text {sup } r} * \sqrt{\beta_{m} \beta_{C}} * \cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}} * \sin ^{2} \frac{n \Phi_{C}}{2}=\delta_{a r c} \sqrt{\beta_{m} \beta_{C}} * \frac{\cos \varphi_{m}}{\sin \frac{\Phi_{C}}{2}}
$$

$$
\left.\begin{array}{l}
\rightarrow 2 \delta_{\text {sup } r} \sin ^{2}\left(\frac{n \Phi_{C}}{2}\right)=\delta_{\text {arc }} \\
\rightarrow \sin \left(n \Phi_{C}\right)=0
\end{array}\right\} \delta_{\text {sup } r}=\frac{1}{2} \delta_{\text {arc }}
$$

and at the same time the phase advance in the arc cell has to obey the relation:

$$
n \Phi_{C}=k^{*} \pi, k=1,3, \ldots
$$
