# Higgs boson production/decay

- Higgs boson couplings measurement essential SM consistency test
- Search for rare production modes
  - Continue search for additional states at high mass in parallel

- WW channel well-suited to exploring rare production modes and searching at high-mass
  - Large branching ratio: **22 %**
  - Good S/B from clean dilepton signature

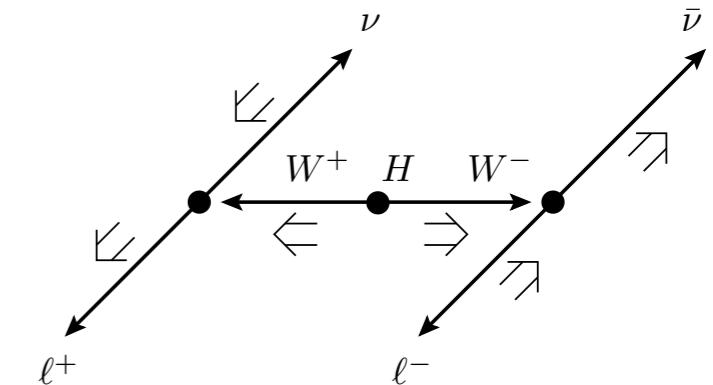

# $H \rightarrow WW^* \rightarrow l\nu l\nu$ Signature

## Final state:

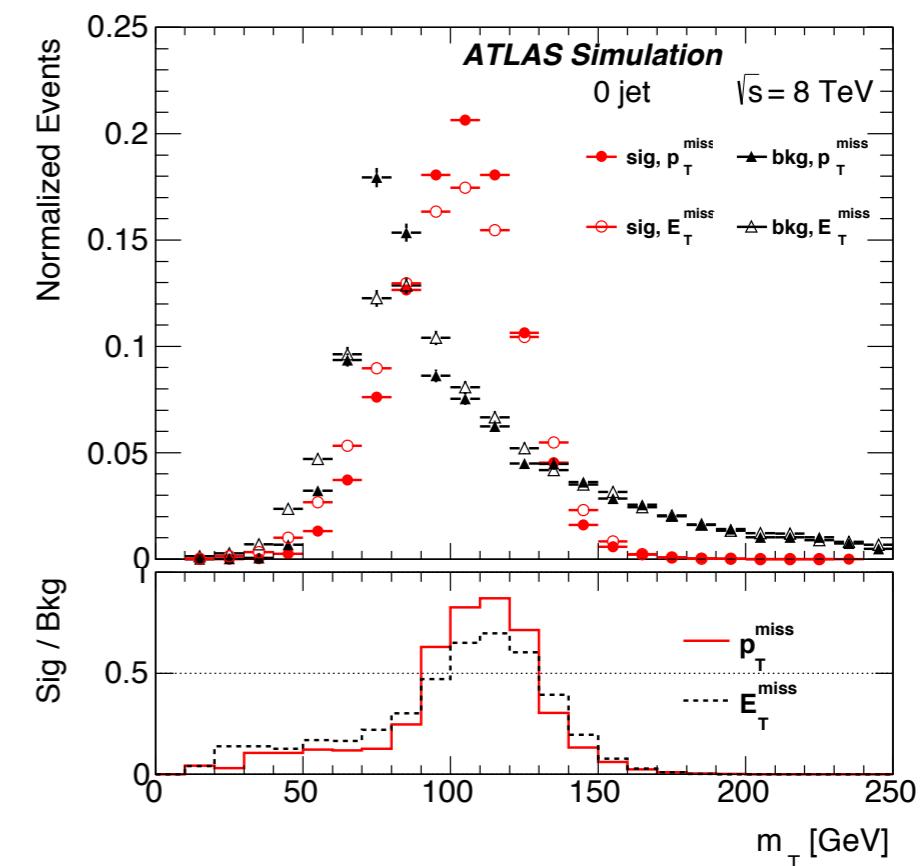

- ▶ 2 charged leptons
- ▶ 2 neutrinos
- ▶ n jets depend on the production mode

**Spin zero Higgs:**  
charged leptons  
prefer to point in  
same direction

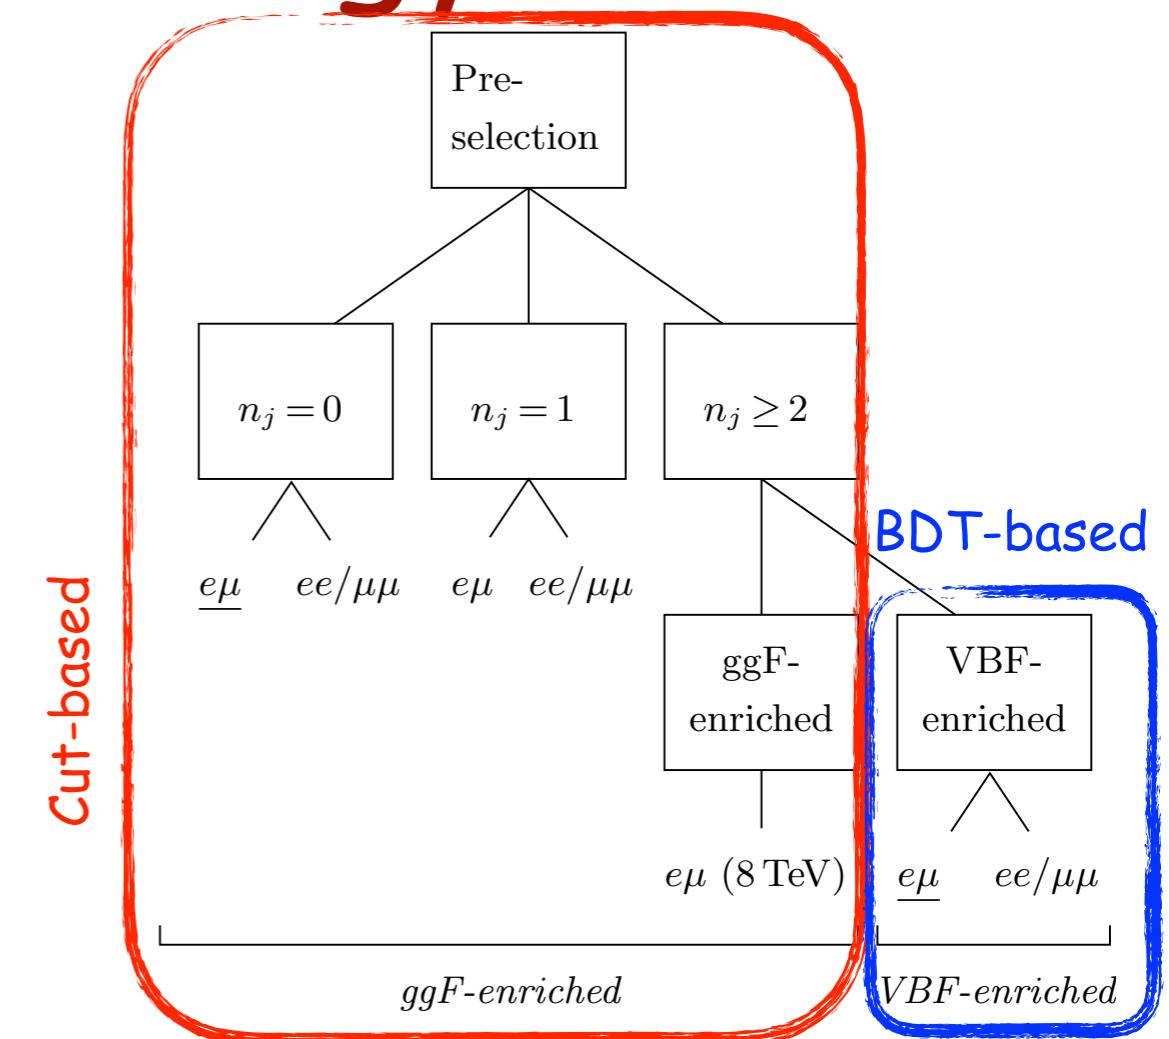

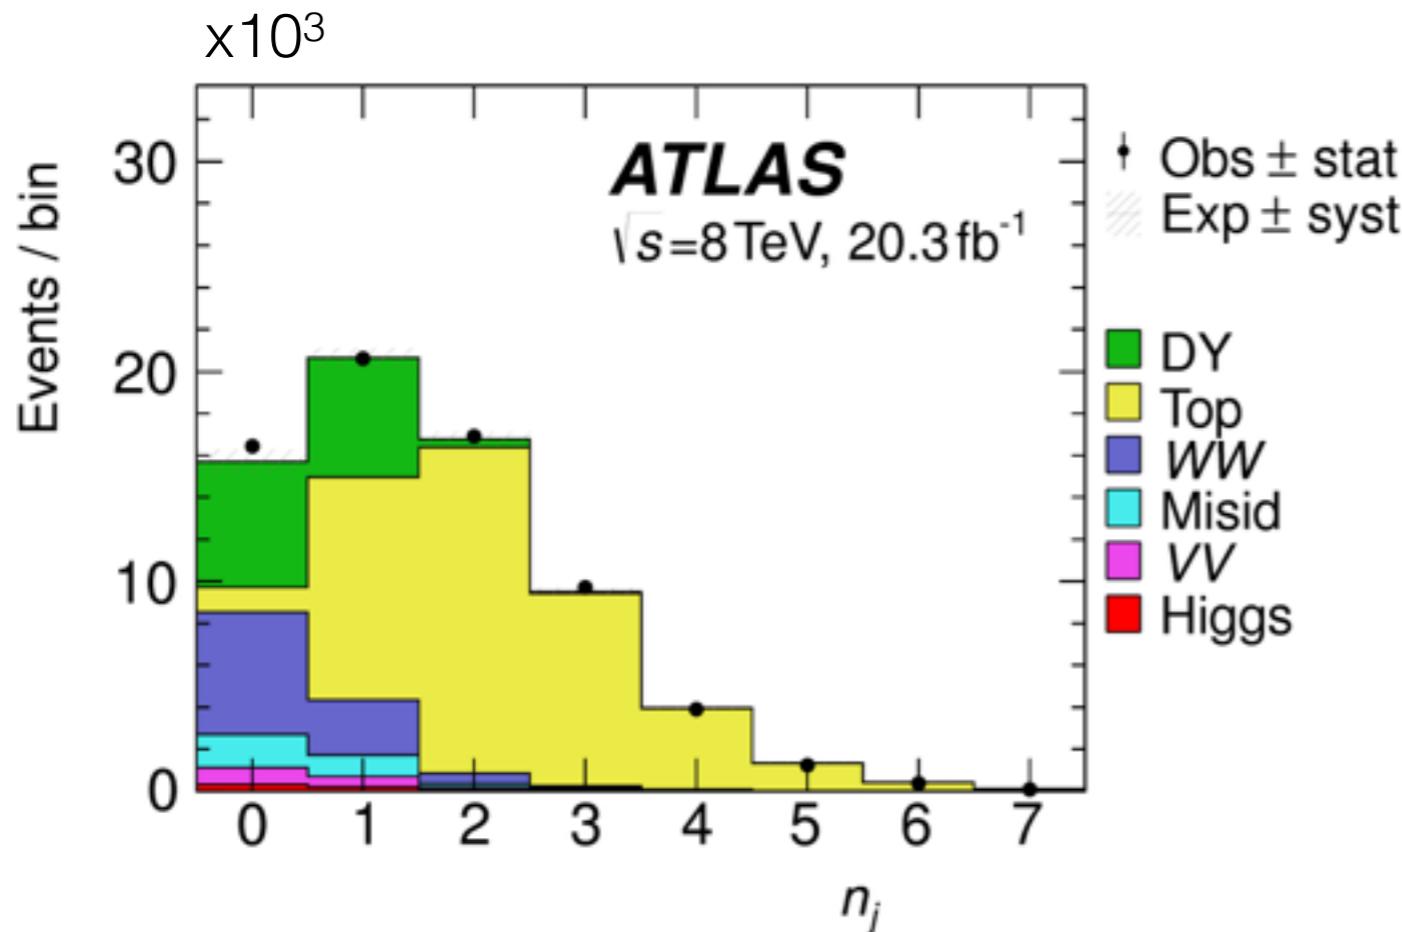

- Signal process can not be fully reconstructed → presence of neutrino
  - A transverse mass  $m_T$  can be calculated without the unknown longitudinal neutrino momenta

$$M_T^2 = (E_T^{\ell\ell} + E_T^{\text{miss}})^2 - (\vec{p}_T^{\ell\ell} + \vec{E}_T^{\text{miss}})^2$$

# Analysis strategy

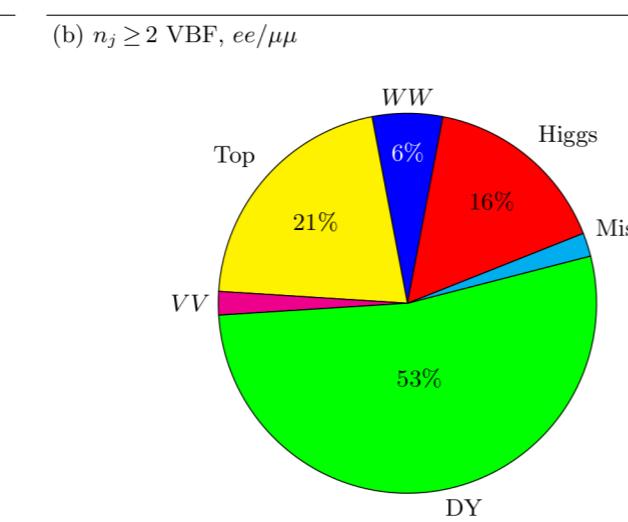

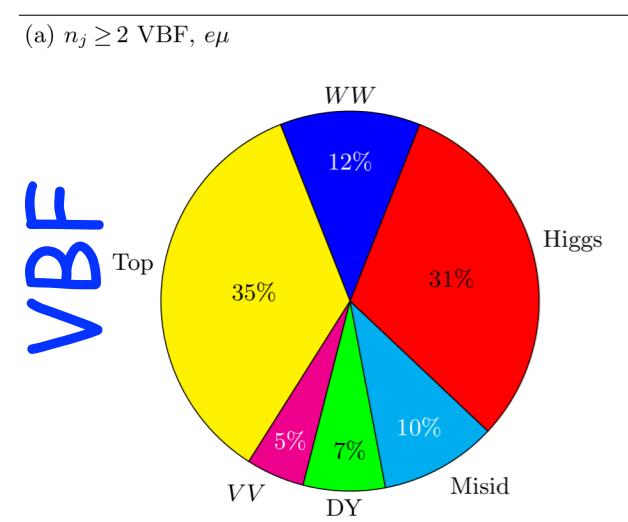

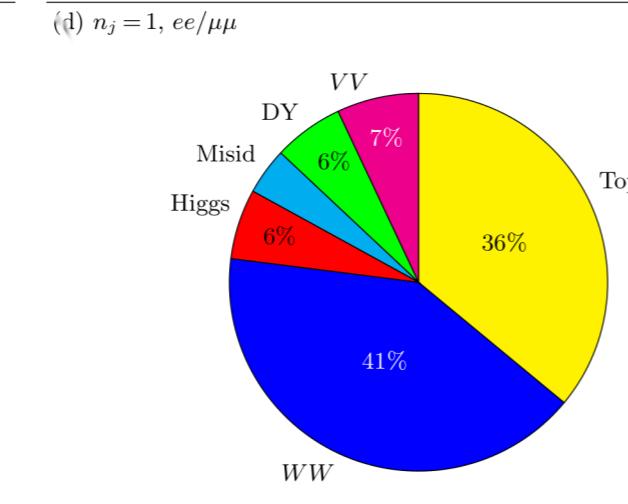

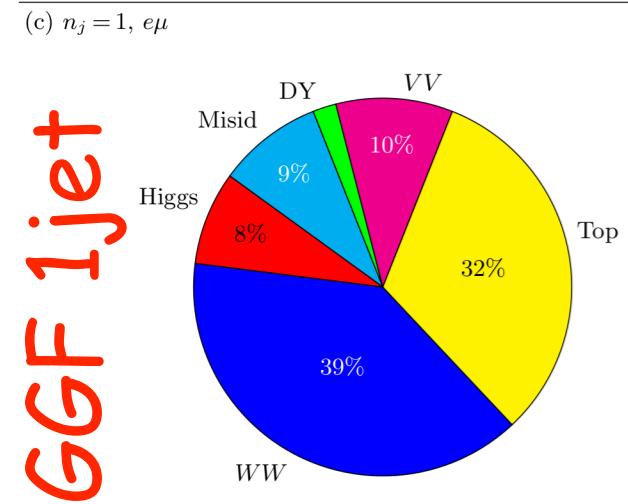

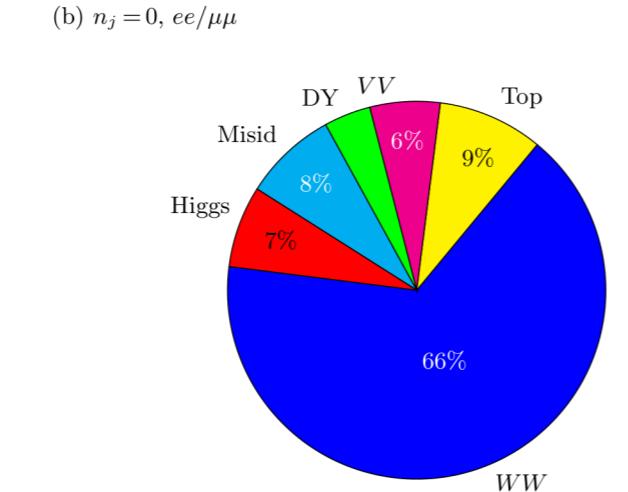

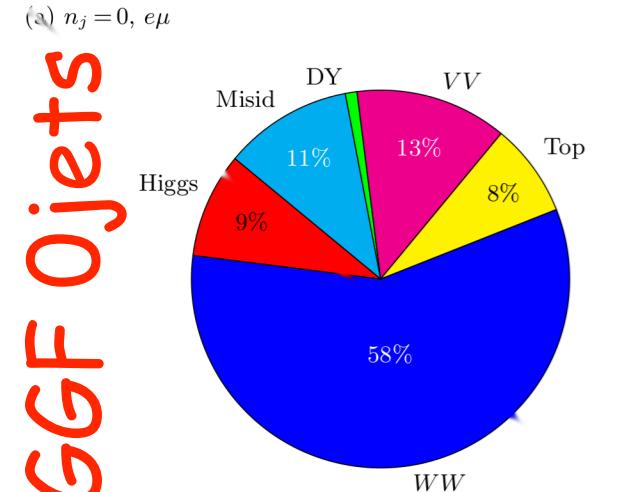

- Categorise events by number of jets, number of leptons, lepton flavors
- Separate by production mode and background composition
- Cut away backgrounds and normalise to control regions enriched in a particular background but orthogonal to the signal region

# Backgrounds

## GGF Objects

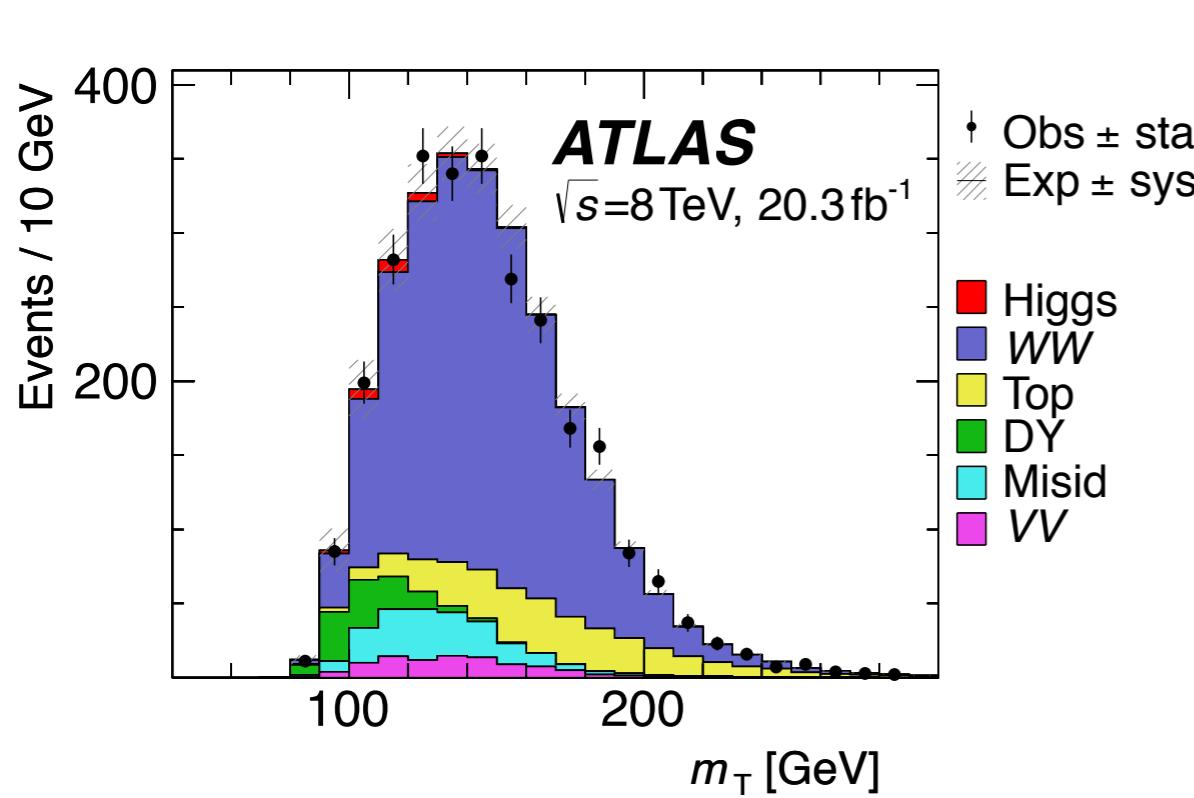

## VBF

- **WW**: dominant ggF background → almost irreducible
- **Top**: coming from unidentified b-quark
- **DY**:
  - $Z/\gamma^* \rightarrow ee/\mu\mu$ : Misidentified missing energy
  - $Z/\gamma^* \rightarrow \tau\tau$ : Irreducible
- **Misid**: jet misidentified as lepton
  - “fake” leptons, particularly muons, are often true leptons from heavy-flavor hadron decays
  - dijet data samples are used to obtain the fake factor
  - 40-45% uncertainty on fake factor from sample composition

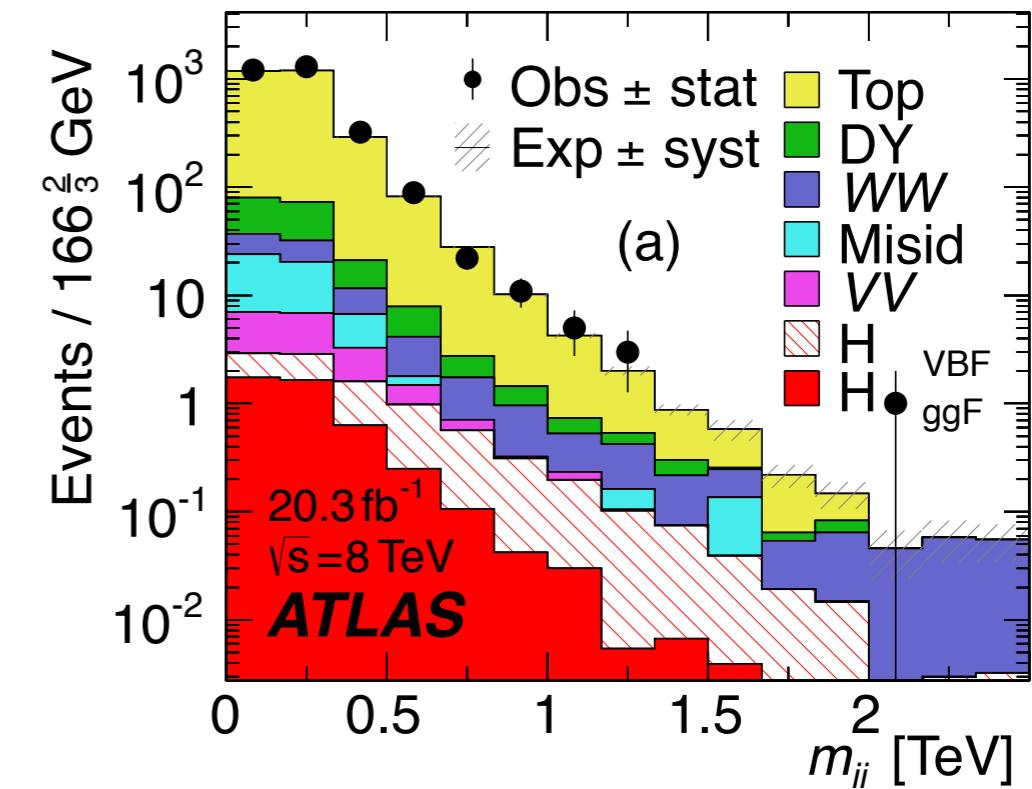

# Backgrounds

## WW background

- $N_{\text{Jets}} < 2$  analyses use  $m_{ll}$  to define the CR
  - process characterised by two lepton with bigger angle wrt Higgs process
  - Invariant mass of the charged leptons combines angular information with the kinematic information associated with Higgs boson mass  $\rightarrow$  powerful discriminant

## Top background

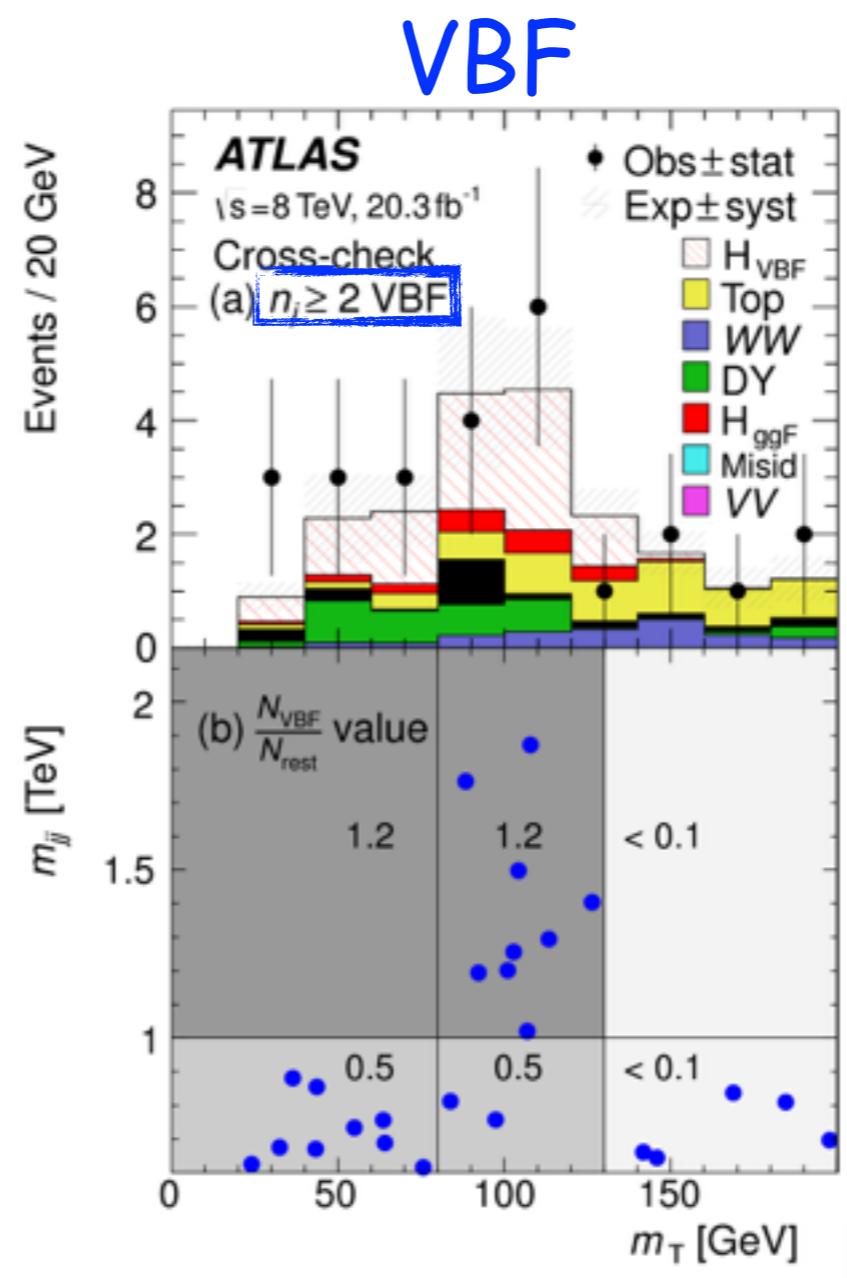

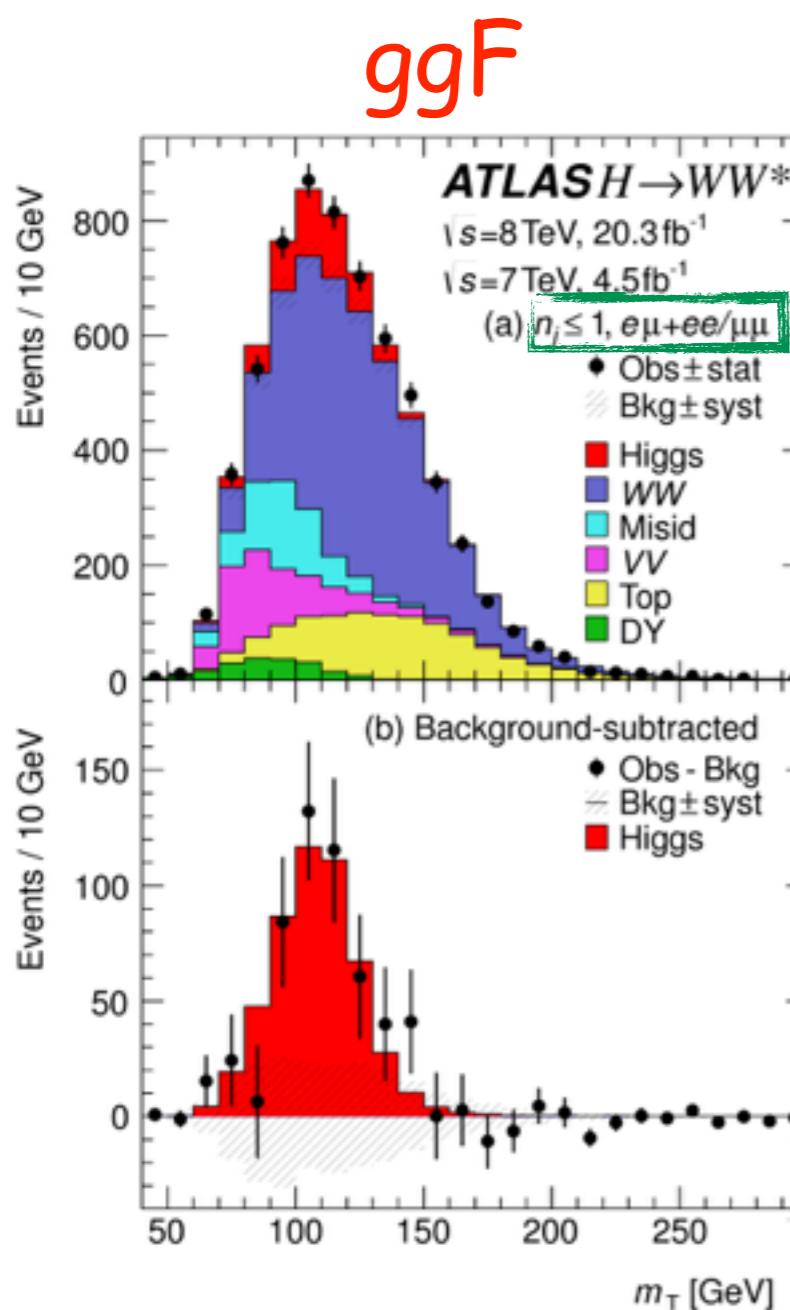

- $N_{\text{Jets}} > 1$  categories have a large contribution from top-quark background
- Light-quark et from initial-state radiation and a b-quark jet that is not identified by the b -tagging algorithm
- CR requires exactly one b-tagged jet to mimic this topology

# H $\rightarrow$ WW $^*$ $\rightarrow$ l $\nu$ l $\nu$ signal strength

$$\begin{array}{lllll} \mu_{ggF} & = 1.02 & \pm 0.19 & ^{+0.22}_{-0.18} & = 1.02 & ^{+0.29}_{-0.26} \\ \mu_{VBF} & = 1.27 & ^{+0.44}_{-0.40} & ^{+0.30}_{-0.21} & = 1.27 & ^{+0.53}_{-0.45} \\ & & & & (\text{stat}) & (\text{syst}) \end{array}$$

$$\begin{aligned}\sigma_{\text{ggF}}^{\text{7TeV}} \cdot \mathcal{B}_{H \rightarrow WW^*} &= 2.0 \pm 1.7^{+1.2}_{-1.1} = 2.0^{+2.1}_{-2.0} \text{ pb} \\ \sigma_{\text{ggF}}^{\text{8TeV}} \cdot \mathcal{B}_{H \rightarrow WW^*} &= 4.6 \pm 0.9^{+0.8}_{-0.7} = 4.6^{+1.2}_{-1.1} \text{ pb} \\ \sigma_{\text{VBF}}^{\text{8TeV}} \cdot \mathcal{B}_{H \rightarrow WW^*} &= 0.51^{+0.17}_{-0.15} {}^{+0.13}_{-0.08} = 0.51^{+0.22}_{-0.17} \text{ pb.} \\\text{(stat) (syst)}\end{aligned}$$

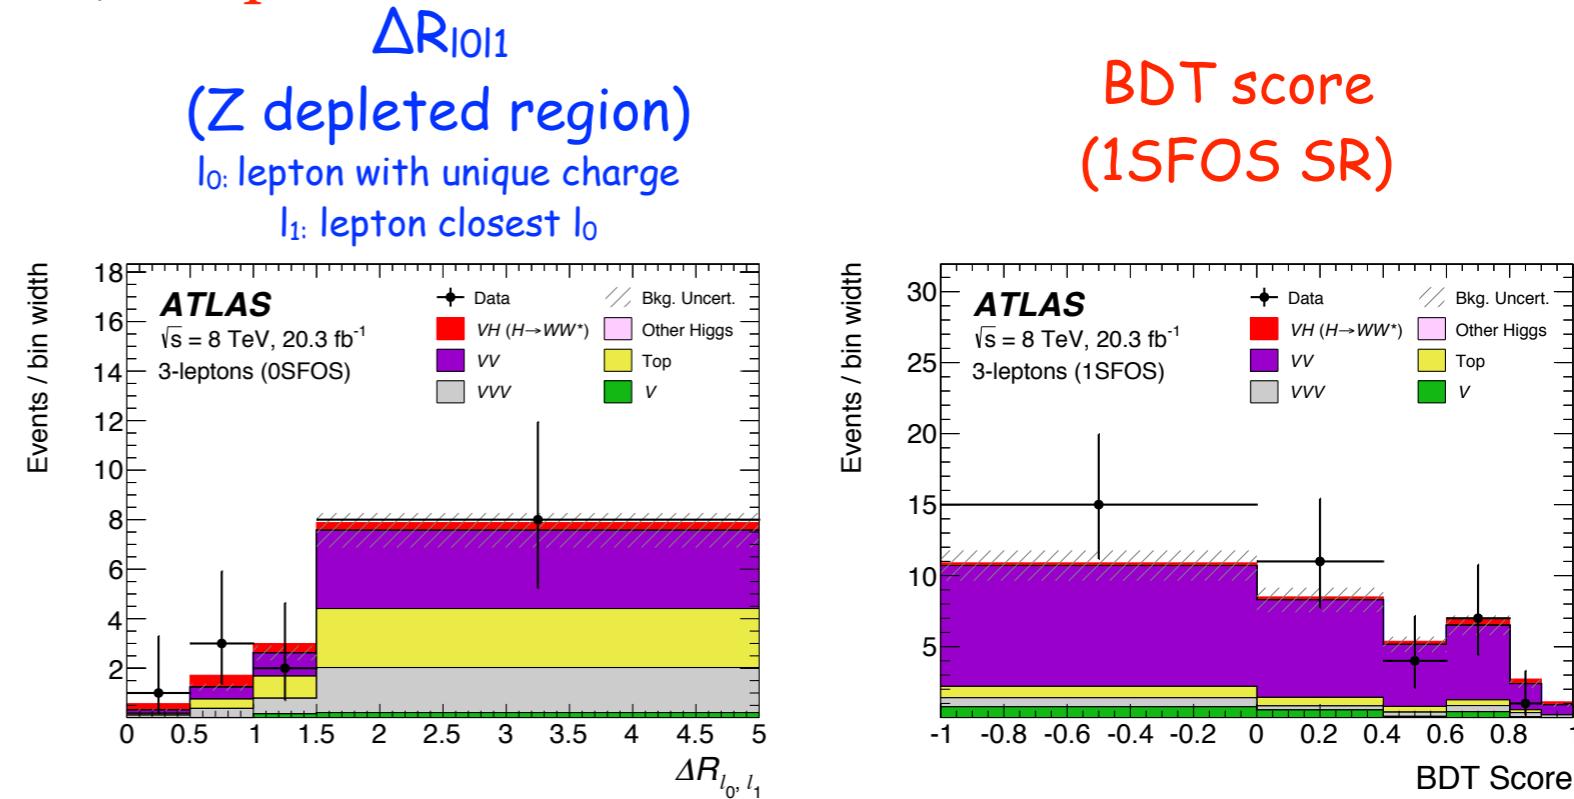

- $\mu = \sigma/\sigma_{\text{SM}}$  // measured cross section  $\sigma = \mu * \sigma_{\text{SM}}$ 
    - Fiducial cross section not affected by the theoretical uncertainties on the total signal yield
  - ▶ Confirmed Higgs boson decay to W bosons → rate consistent with the Standard Model : observed significance of 5.8 standard deviations
  - ▶ Evidence of VBF production in this channel → observed significance of 3.2 standard deviations

# VH $\rightarrow$ WW Signal Regions

Clean 3-lepton (WH) and 4-lepton (ZH) signatures, additional info on HWW vertex (complement to VBF mode)  $\rightarrow$  pure HWW or HZZ

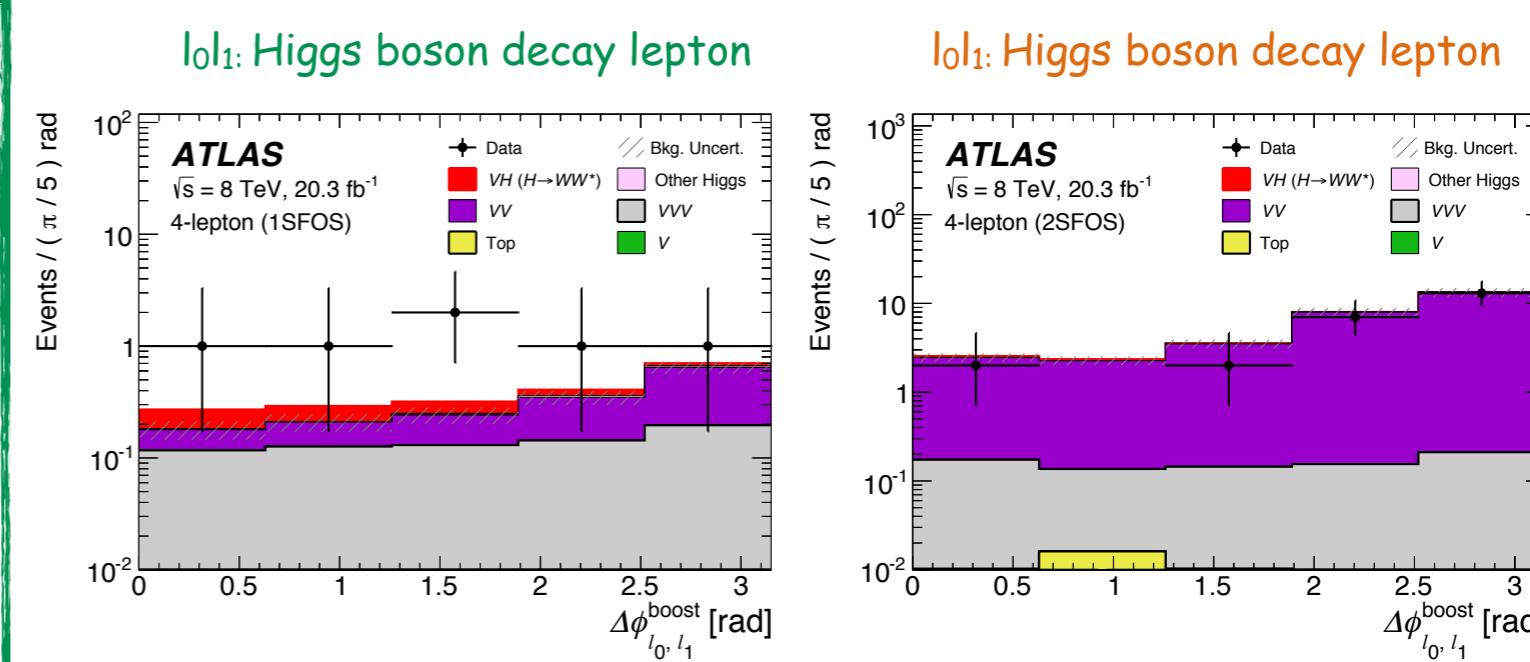

WH  $\rightarrow$  3-leptons

- Major backgrounds are WZ/Wy\*, ZZ\*, VVV
- Split into Z enriched and Z depleted regions using number of same flavour (SF) opposite sign (OS) lepton pairs

ZH  $\rightarrow$  4-leptons:

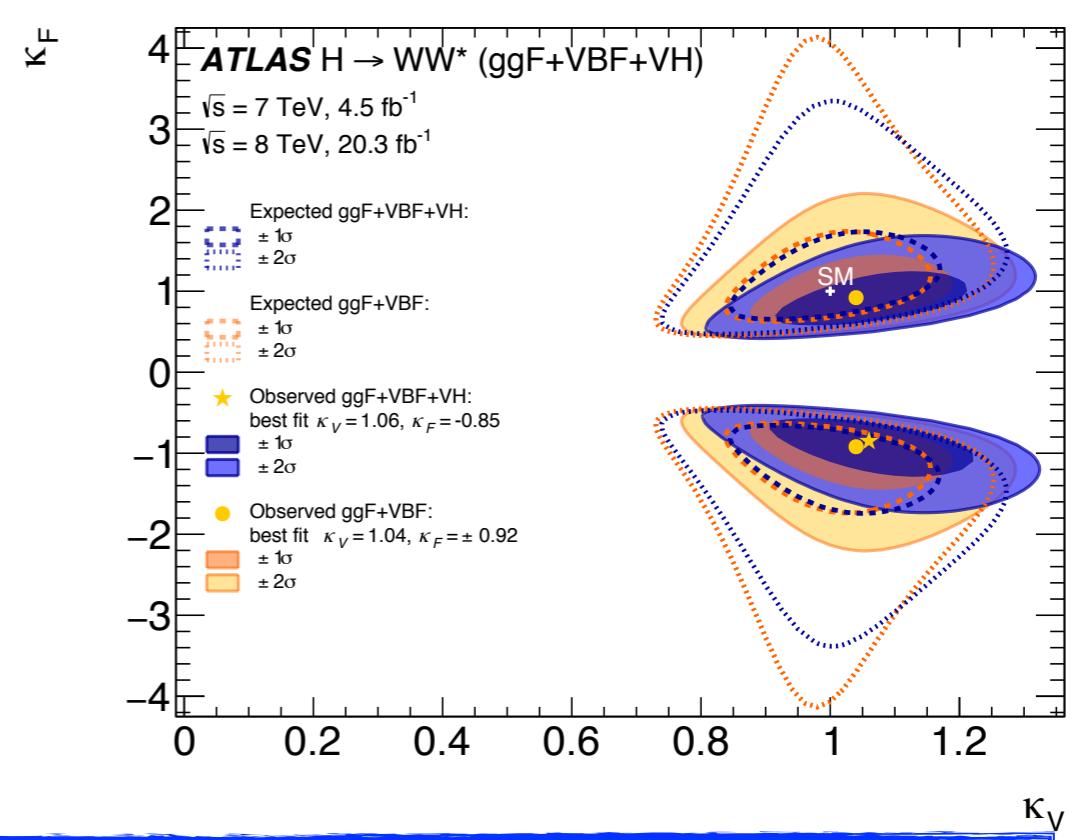

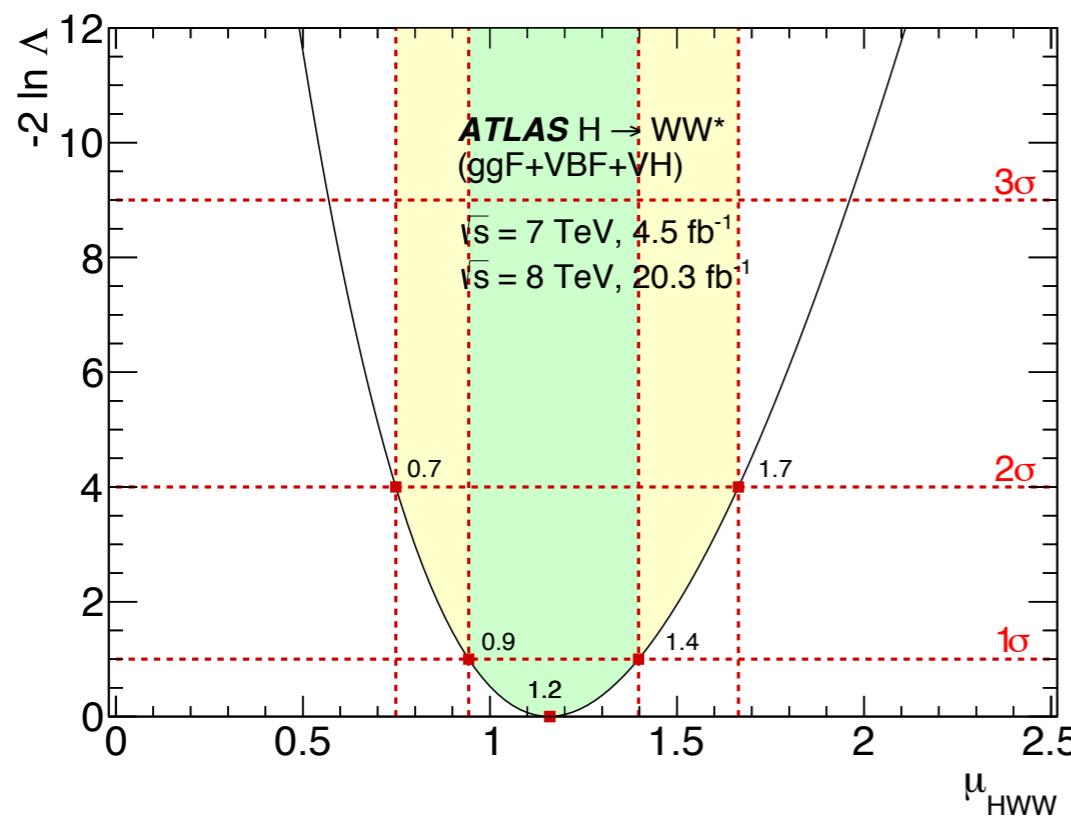

- 2 OS pairs, one with  $|m_{ll} - m_Z| < 10$  GeV 1 event expected, S/B  $\sim 1/5$  zero observed
- Main background is ZZ\*
- Split SR into 1SFOS and 2SFOS to better control ZZ\* bkg

# Combined $H \rightarrow WW$ Results ( $m_H = 125.36$ GeV)

Category	Signal significance $Z_0$			Observed signal strength $\mu$					
	Exp. $Z_0$	Obs. $Z_0$	Obs. $Z_0$	$\mu$	Tot. err.		Syst. err.		$\mu$
					+/-	+/-	+/-	+/-	
ggF	4.4	4.2		<b>0.98</b>	0.29	0.26	0.22	0.18	
VBF	2.6	3.2		<b>1.28</b>	0.55	0.47	0.32	0.25	
$VH$	0.93	2.5		<b>3.0</b>	1.6	1.3	0.95	0.65	
$WH$ only	0.77	1.4		<b>2.1</b>	1.9	1.6	1.2	0.79	
$ZH$ only	0.30	2.0		<b>5.1</b>	4.3	3.1	1.9	0.89	
ggF+VBF+VH	5.9	6.5		<b>1.16</b>	0.24	0.21	0.18	0.15	

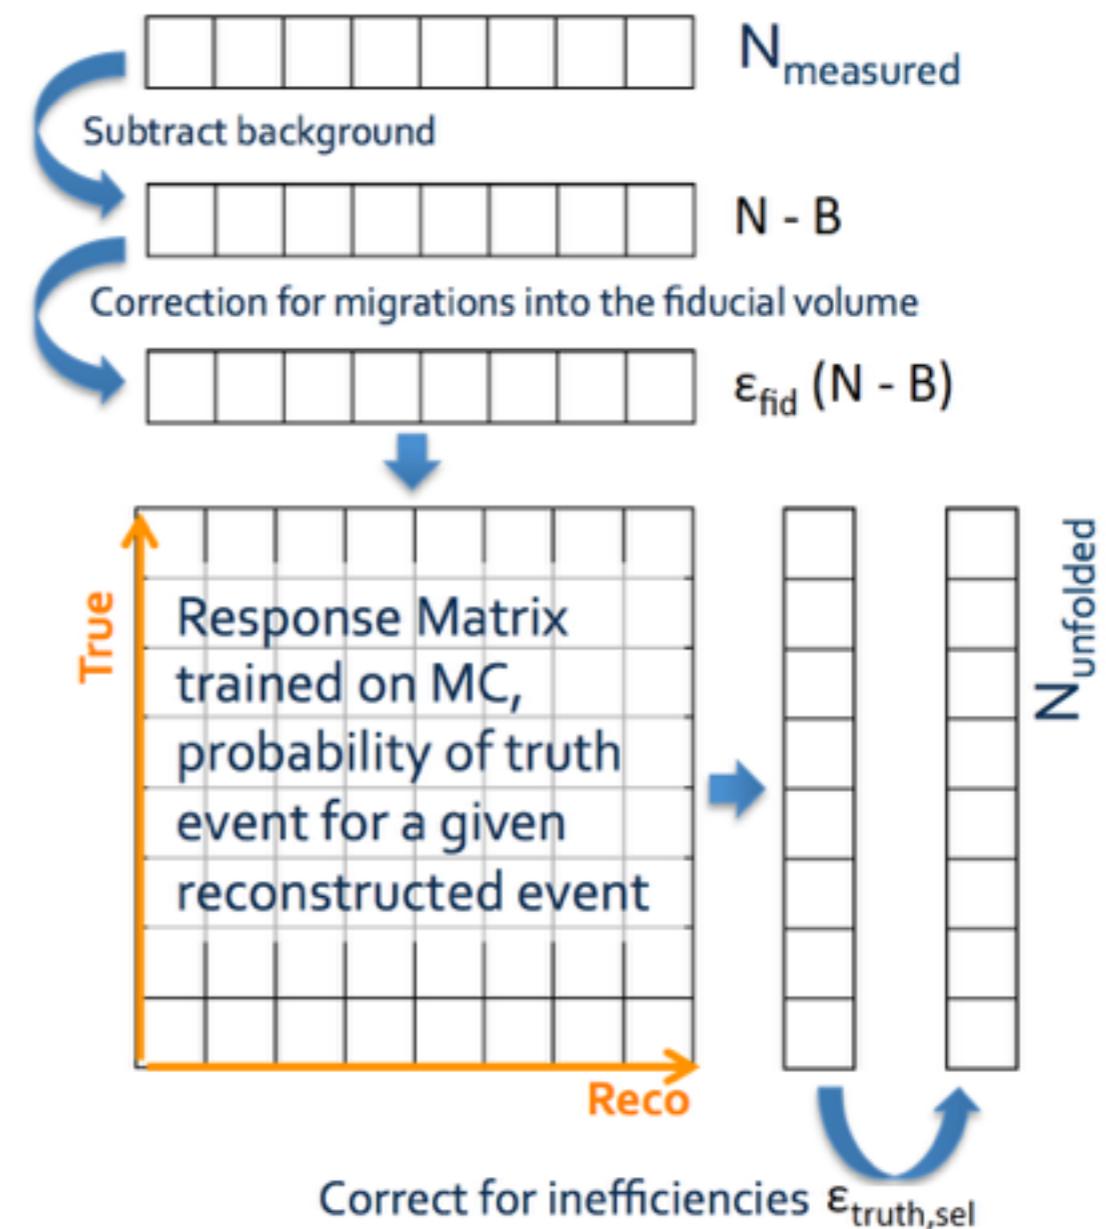

- Observed significance for the combined VH production is 2.5 standard deviations
- Significance of 0.9 standard deviations is expected in the SM Higgs boson hypothesis

# Differential Cross Sections

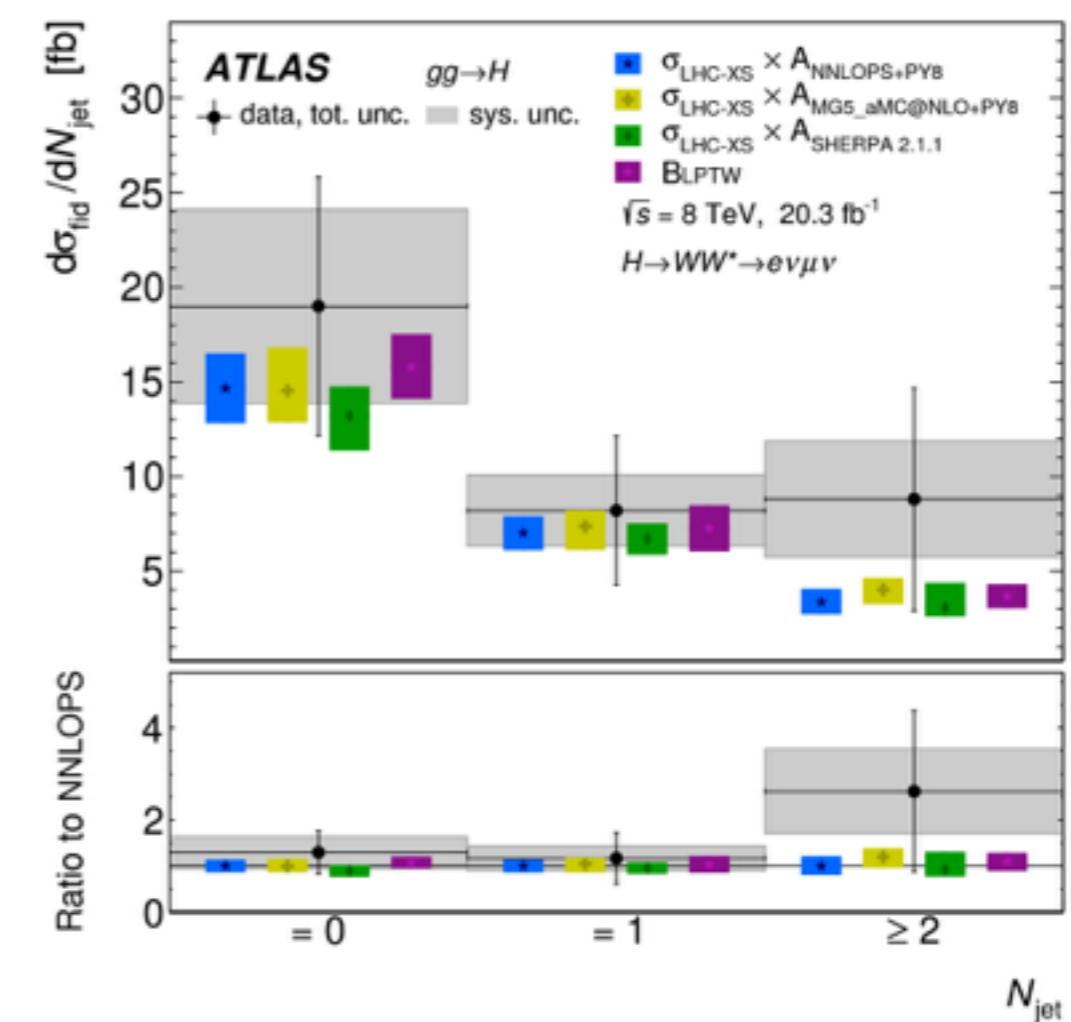

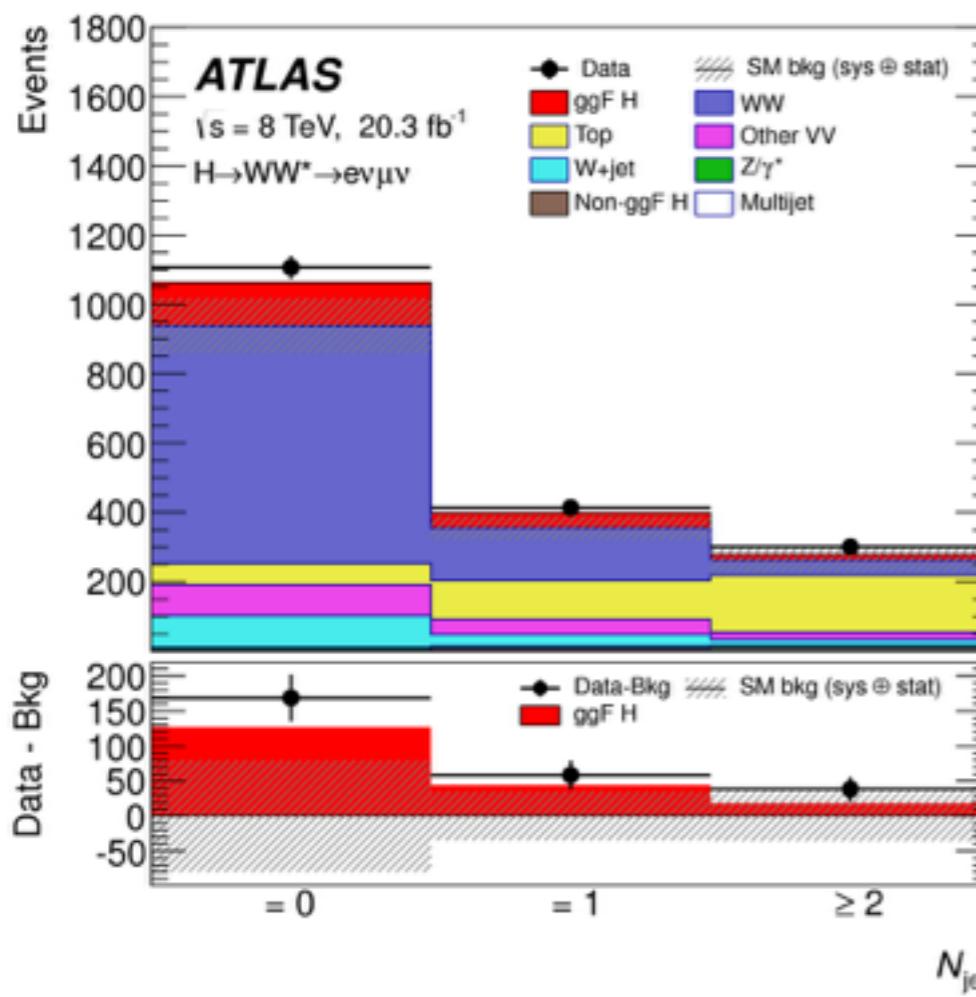

- Possible to directly measure several kinematic distributions in a close to model independent way
  - Compare to theoretical models and provide constraints on QCD and PDF calculation
  - Sensitive to new physics
- Analysis performed only on different flavour
- Use control region to extract background and subtract the predicted background in the signal region from the data
- Correction/extrapolation of the event yields from the reconstructed signal region to the truth-level fiducial volume
- Unfolding corrects measured distribution for detector effects and brings it from the signal (reconstructed) to the fiducial (particle level) volume

$$\frac{d\sigma}{dX_i} = \frac{1}{\mathcal{L} * BR} \frac{M_{ji}^{-1} \epsilon_{fid,j}}{\epsilon_{truth,sel,i}} (N_j - B_j)$$

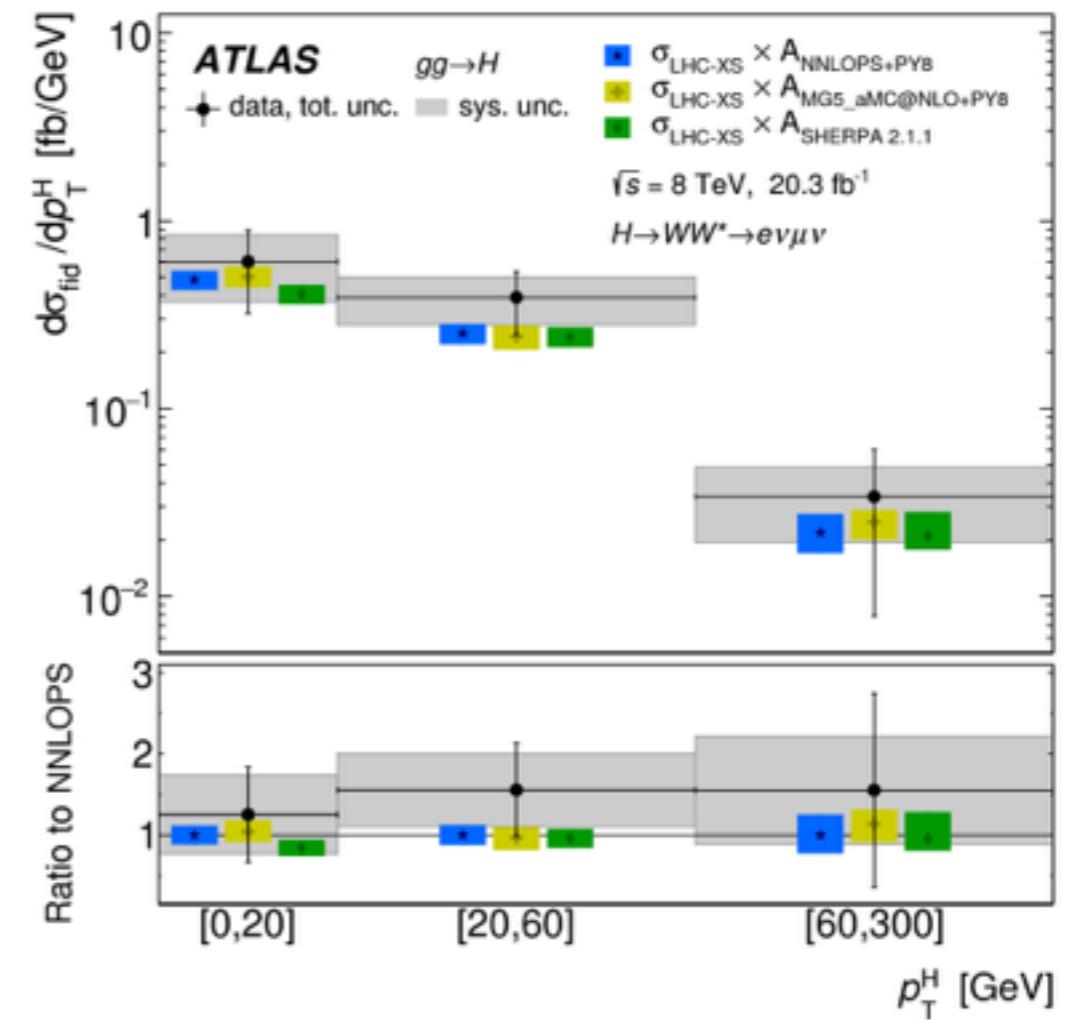

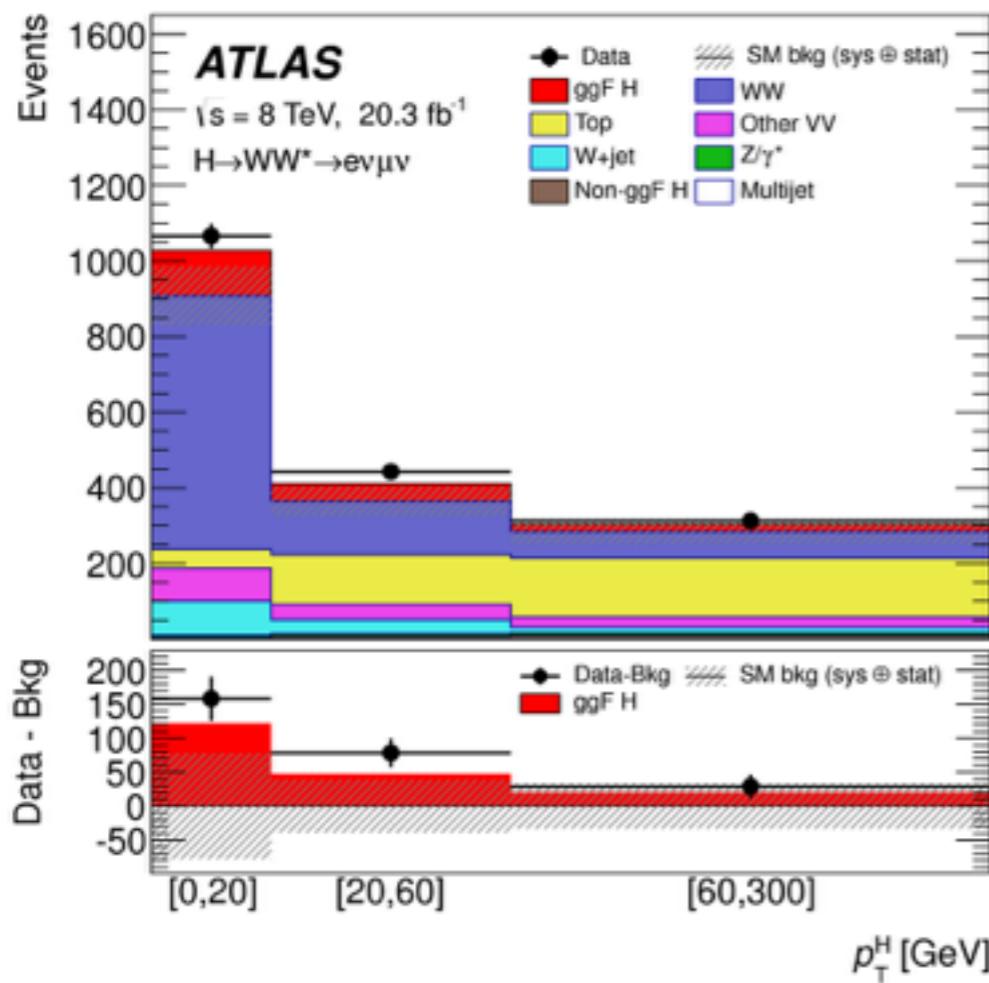

# Differential Cross Sections

- Jet multiplicity  $N_{\text{jets}}$ : a measure of the QCD radiative process in the initial state. Reflects the hard QCD process, calculations lack precise prediction for the high  $N_{\text{jets}}$
- Statistical uncertainties (25%-75%) still dominate all the differential measurements

# Differential Cross Sections

- Transverse momentum  $p_T^H$  directly probes perturbative/soft QCD, sizeable uncertainties at low  $p_T$
- Statistical uncertainties (25%-75%) still dominate all the differential measurements

# Summary

- WW was essential to discovery, combined rate measurement, and connecting the new particle to electroweak symmetry breaking
- WW channel can be very useful in investigation the Higgs boson nature
  - ▶ Good S/B and large branching ratio
  - ▶ Challenging backgrounds in ggF and VBF
- ggF and VBF modes key inputs to coupling measurement combinations
- Search for rarer production modes: WH, ZH
- Total fiducial cross BR is obtained by summing the three bins on the Njet distribution

$$\sigma_{\text{ggF}}^{\text{fid}} = 36.0 \pm 7.2(\text{stat}) \pm 6.4(\text{sys}) \pm 1.0(\text{lumi}) \text{ fb}$$
- *The Run 2 data will significantly reduce the statistical uncertainties on the measurements. Future precise measurement will provide more stringent tests of the SM predictions of the Higgs boson properties*

# Backup

# Differential Cross Sections

- Longitudinal angle  $Y_{ll}$ : depends on QCD radiative corrections and PDF. Substantial uncertainties on gluon PDFs for low x, high x and high  $Q^2$
- Statistical uncertainties (25%-75%) still dominate all the differential measurements
