

ATLAS Inner Detector upgrade

Sergio Gonzalez Sevilla (University of Geneva)

on behalf of the ATLAS Inner Detector upgrade community

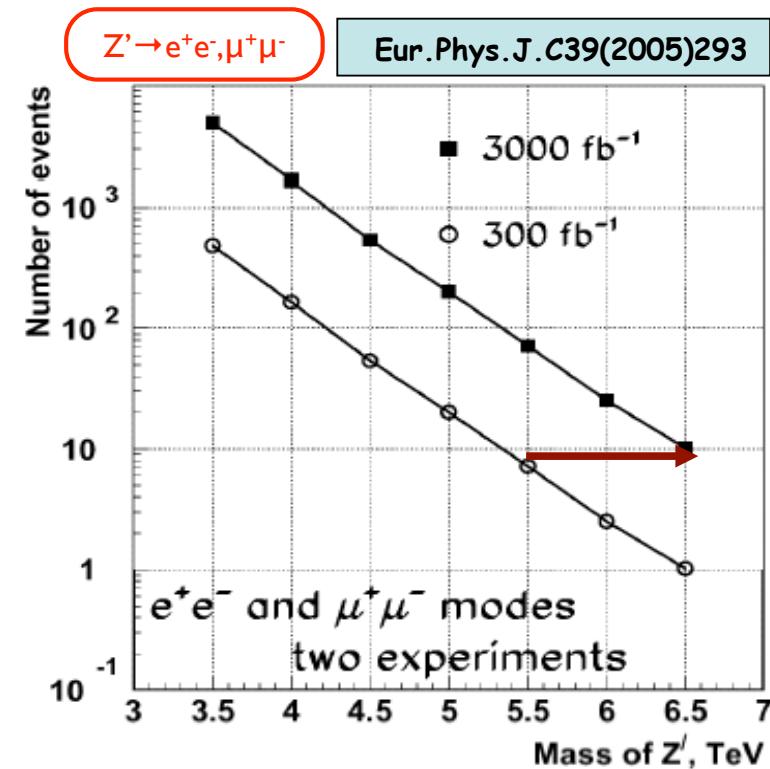

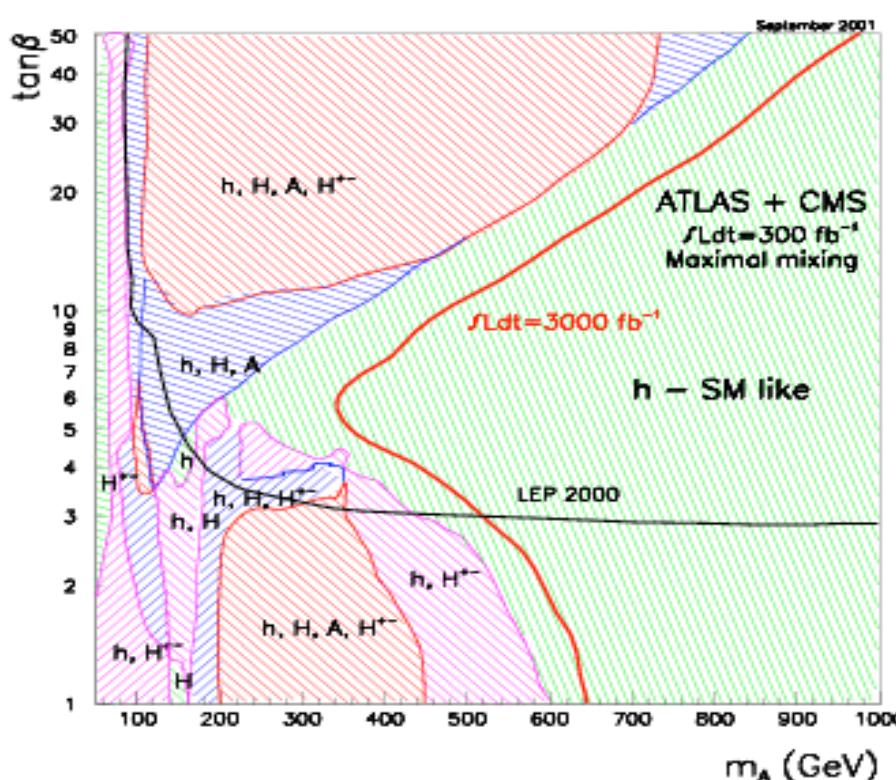

UNIVERSITÉ
DE GENÈVE

3rd LHC Alignment Workshop
CERN - 15/16 June 2009

Physics motivations for a LHC upgrade

- Improve measurements of new phenomena seen at the LHC
 - ▶ Higgs couplings to bosons and fermions and self-couplings
 - ▶ properties of SUSY particles
- Detect/search low-rate phenomena inaccessible at the LHC
 - ▶ $H \rightarrow \mu^+ \mu^-$ ($BR \sim O(10^{-4})$), $H \rightarrow Z\gamma$ ($BR \sim O(10^{-3})$ in $M_H \sim 100-160$ GeV)
- Increase sensitivity to new high-mass scales
 - ▶ extra gauge bosons (Z' , W') appearing in various extensions of the SM symmetry group

LHC luminosity increase

- Two-phased increase in the LHC peak luminosity

► Phase I (2013) $\rightarrow \mathcal{L} = 3 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

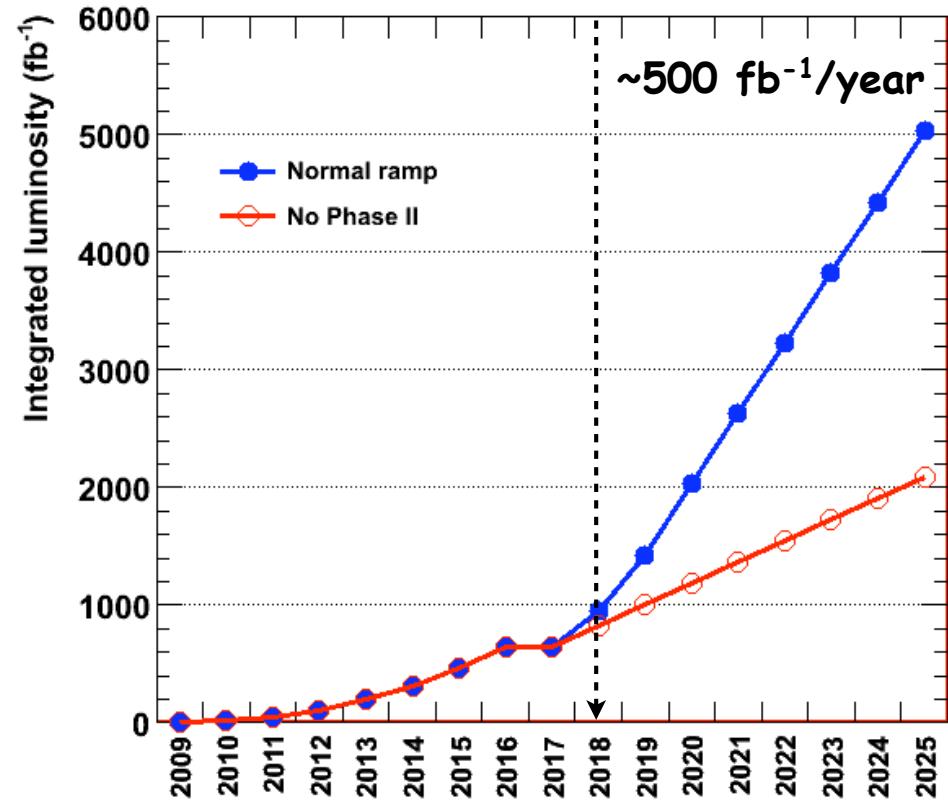

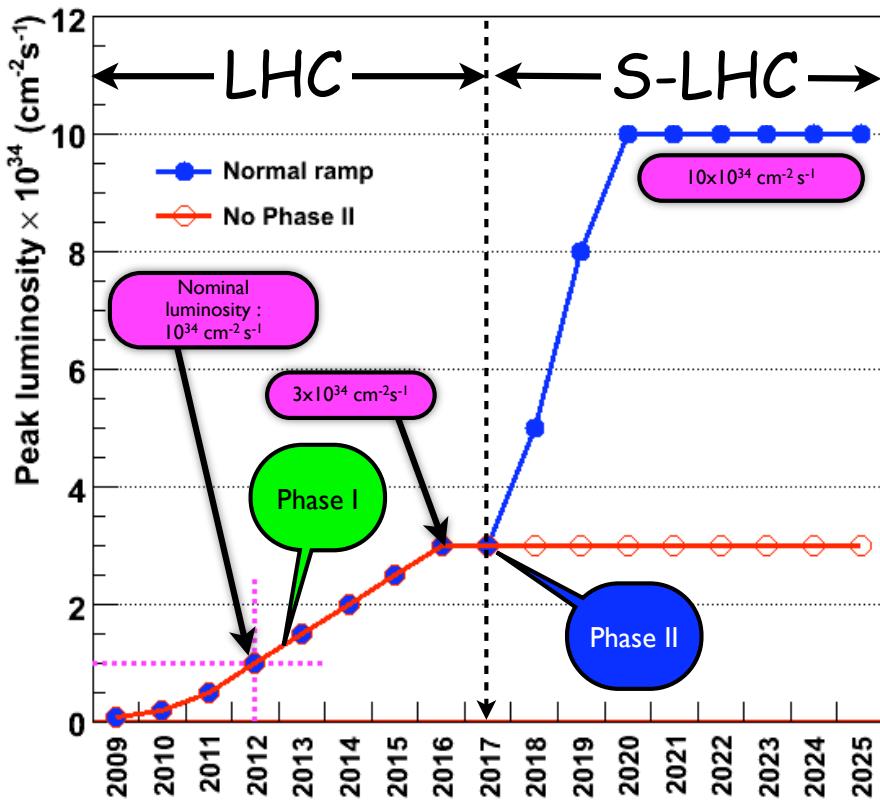

- B-layer replacement

► Phase II (2017) $\rightarrow \mathcal{L} = 10 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

- ATLAS ID upgrade

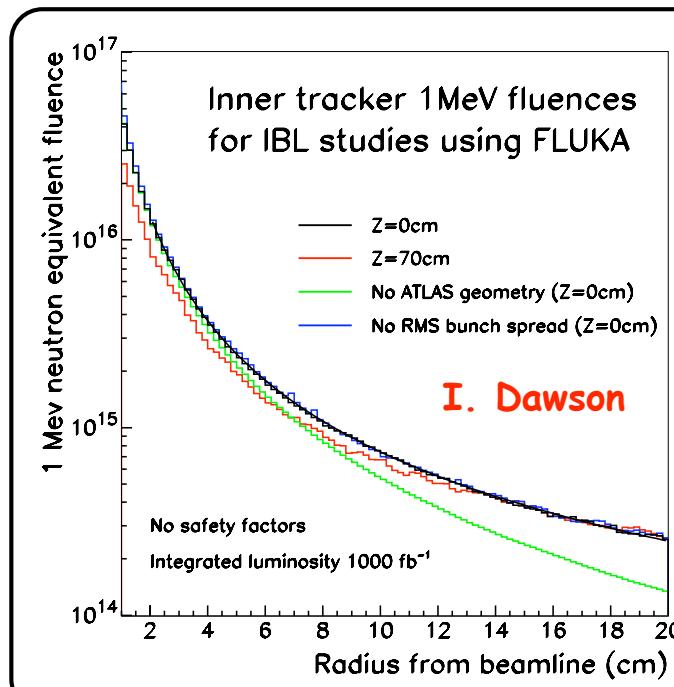

Upgrade of ATLAS and CMS experimental insertions
New large aperture quadrupoles + relevant modifications to other magnets
Upgrade or replacement of LHC injectors (160 MeV Linac4)

New 4 GeV Low Power Superconducting Linac (LPSPL) and 50 GeV Proton Synchrotron (PS2)
Subsequent upgrade of the LPSPL to a multi-MW high power SPL
Associated modifications to the SPS

B-layer issues

- B-layer operational ($\epsilon > 95\%$, single hit) up to a total dose twice the nominal design lifetime
 - ▶ ~5 years @ $10^{34} \text{ cm}^{-2}\text{s}^{-1}$
 - 1 year nominal LHC lumi (100 fb^{-1}): $\sim 15 \text{ Mrad TID}$ for current B-layer @5.0cm
- Marginal operation until 2016 → intervention during the 2012/2013 shutdown
- Requirements and constraints
 - ▶ Physics: b-tagging
 - pattern recognition, hit resolution, material budget
 - ▶ Radiation background
 - ▶ Time...
- Other requirements
 - IBL peak lumi = $3 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$
 - Int. lumi seen by IBL = 550 fb^{-1}

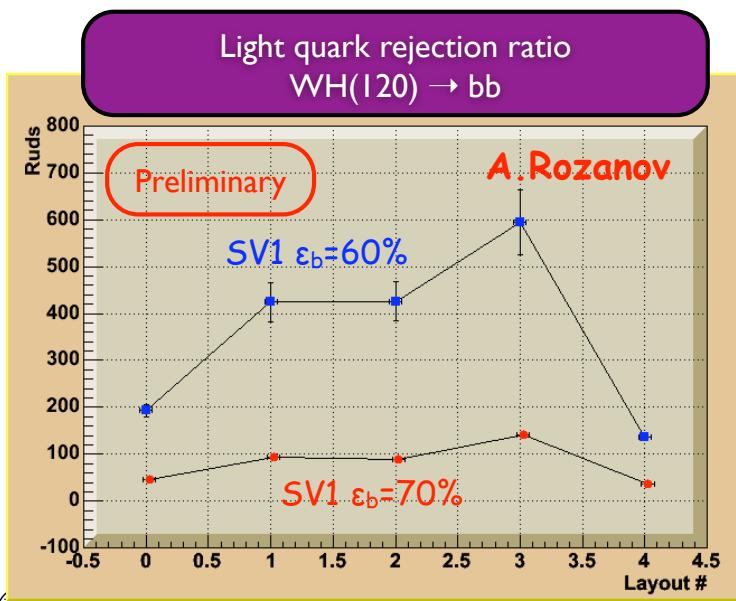

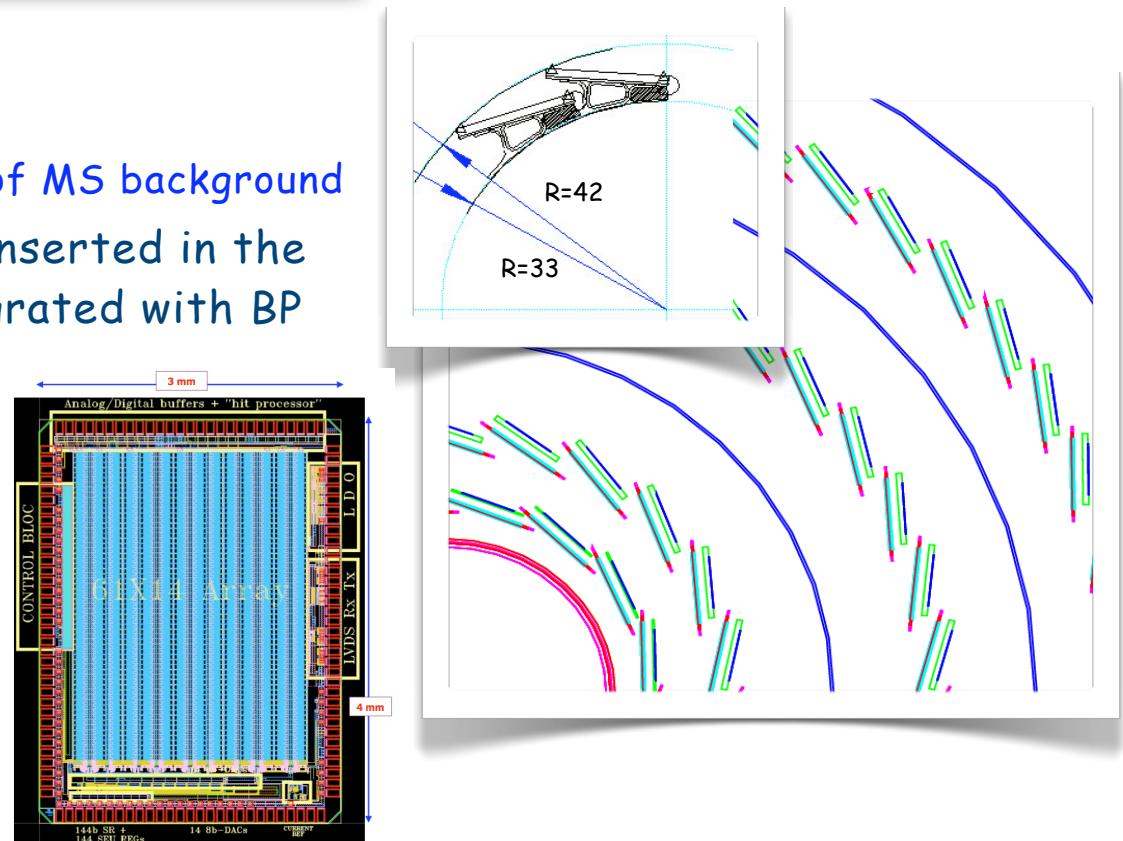

Estimated 1 MeV n_{eq} fluence for IBL:
 $\Phi_{1\text{MeV}} = 2.4 \times 10^{15} [\text{n}_{eq}/\text{cm}^2]$

- dominated by pions from IP
- $R=3.7 \text{ cm}$ and $IL=550 \text{ fb}^{-1}$
- No safety factors included

Phase I: insertable Pixel B-layer

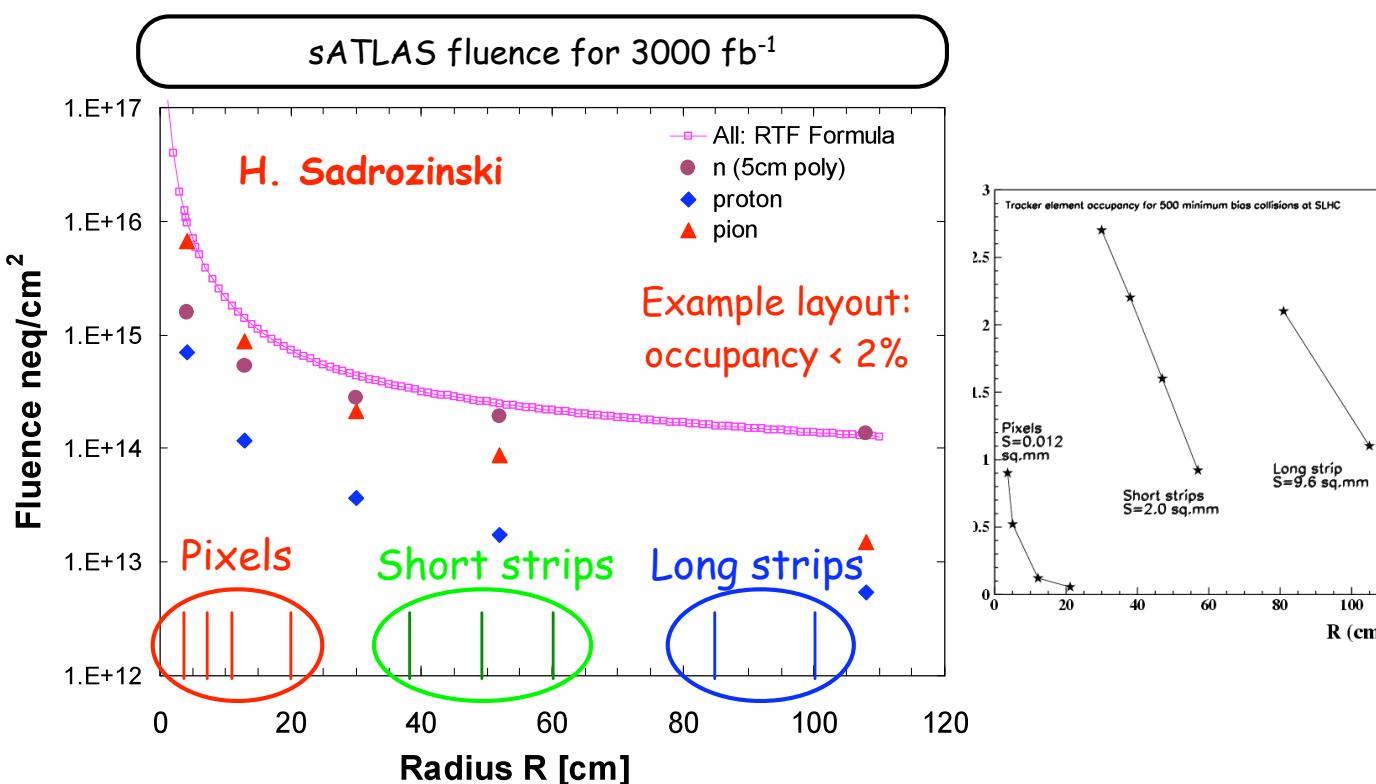

- Most probably, new beam-pipe
 - ▶ $R=25$ mm, $0.7\% X_0$
 - ▶ though expensive, significant reduction of MS background
- Smaller radius B-layer ($R=3.7\text{cm}$) to be inserted in the existing ATLAS Pixel detector and integrated with BP
- New module design:
 - ▶ 16 staves, 15 modules/stave
 - ▶ New readout ASIC FE-I4 chip
 - 130 nm CMOS, $50 \mu\text{m} \times 250 \mu\text{m}$
 - ▶ Novel radhard sensors (3D) ?
- New local support structures (CC foam)

- 0: current ATLAS
- 1: new inserted 4th B-layer ($R=3.7$)
- 2: two Pixel layers
 - new B@ $R=3.7$ + barrel layer @ $R=8.9$ + one disk
- 3: replace old B-layer by new B-layer ($R=5.05\text{cm}$)
- 4: 2-old layers
 - old-type new B@ $R=5.05$ + barrel layer @ $R=8.9\text{cm}$ + one disk

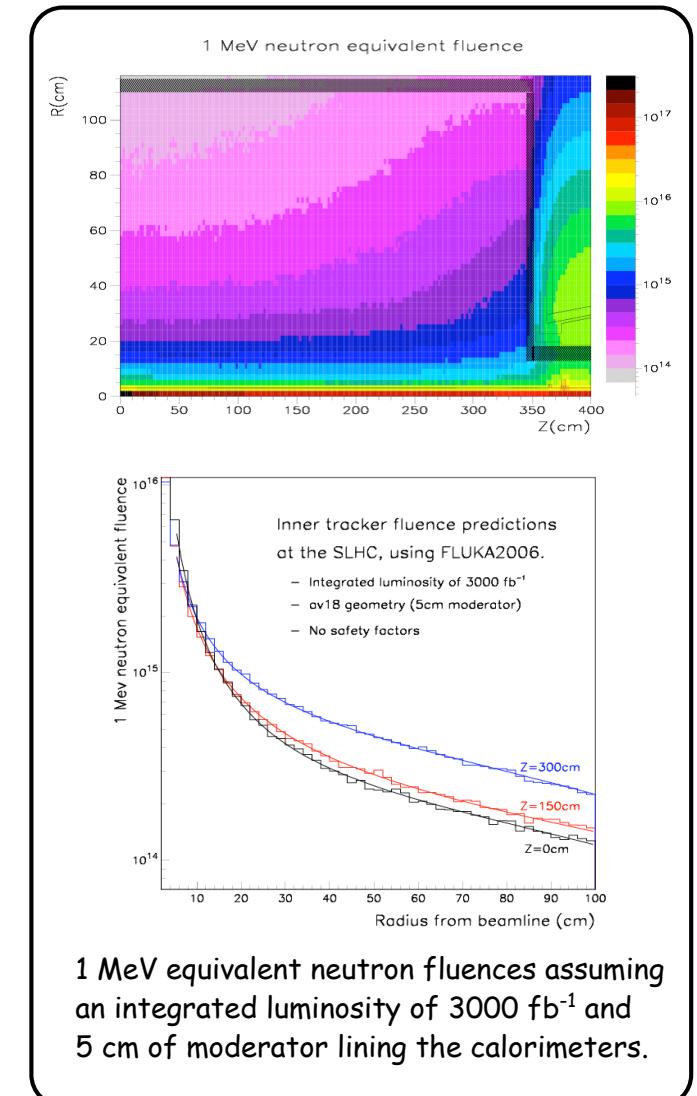

Phase II: a new ATLAS tracker

- Increase in pile-up events from ~23 to ~300-400
 - ▶ Radiation damage
 - ▶ $>10^5$ particles $|n|<3.2 \rightarrow$ occupancy in the TRT ~100%
- Build a completely new ATLAS Inner Detector !!
 - ▶ Pattern reco, good tracking eff+low fake rate, minimise occu
 - better detector granularity
 - ▶ silicon-based tracker: pixels and strips (short and long)

$$\Phi = 1.3 \times 10^{17} / r^2 + 4.8 \times 10^{15} / r + 9.9 \times 10^{13} - 3.6 \times 10^{11} r \quad [n_{eq}/cm^2]$$

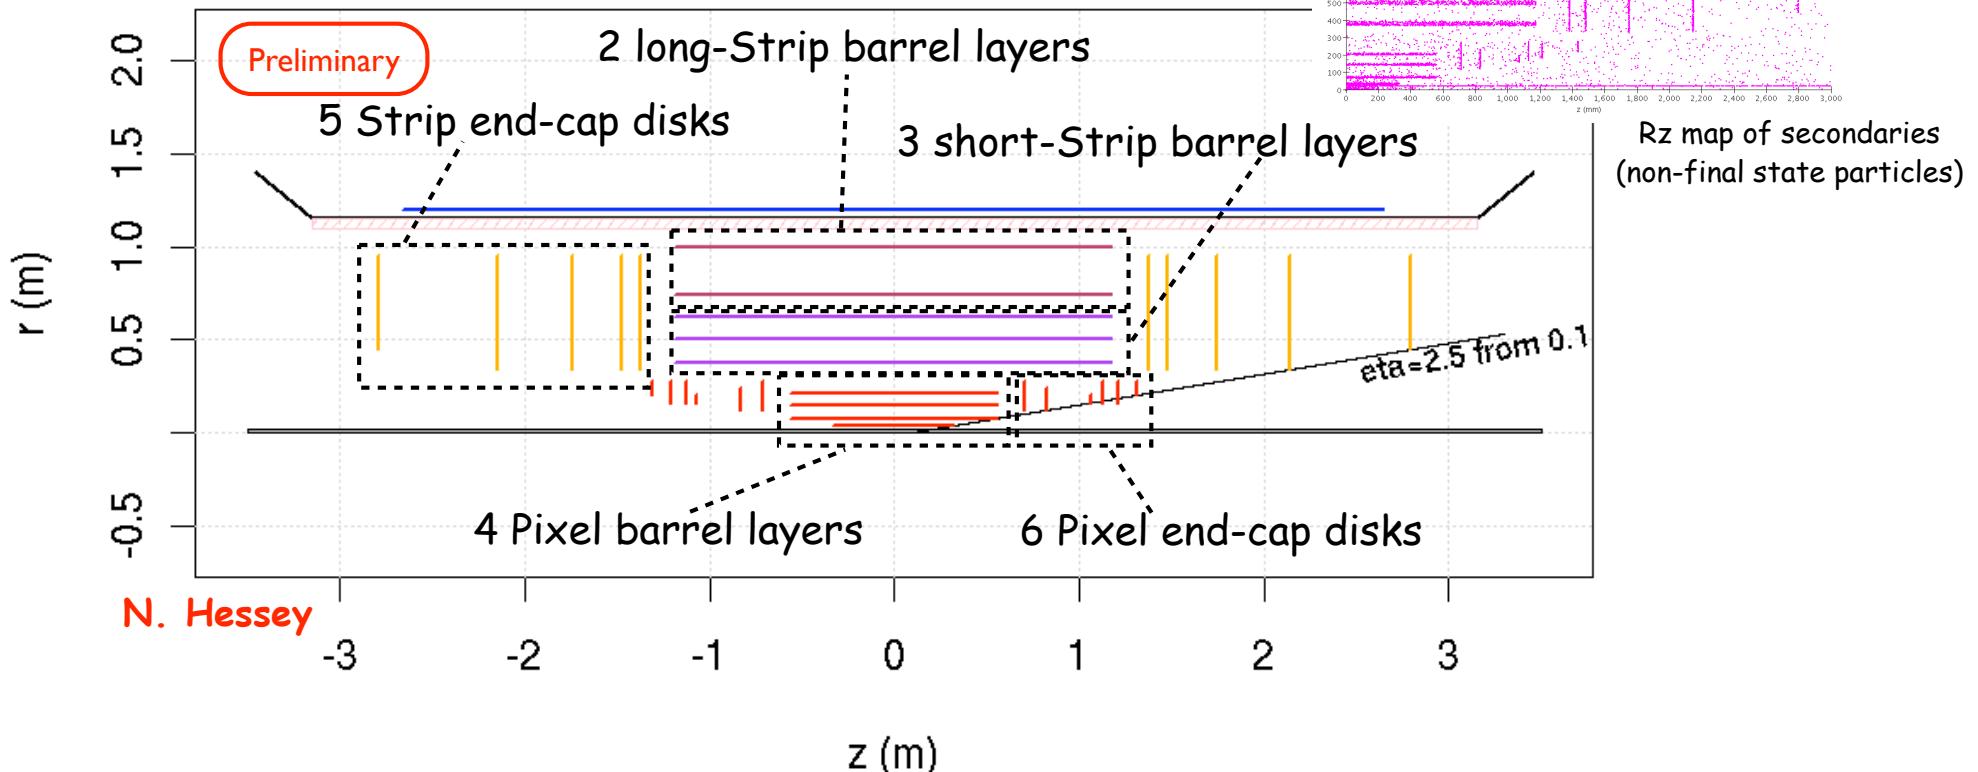

Detector Workshop (CERN) - 15-16 June 09

I. Dawson

Strawman layout

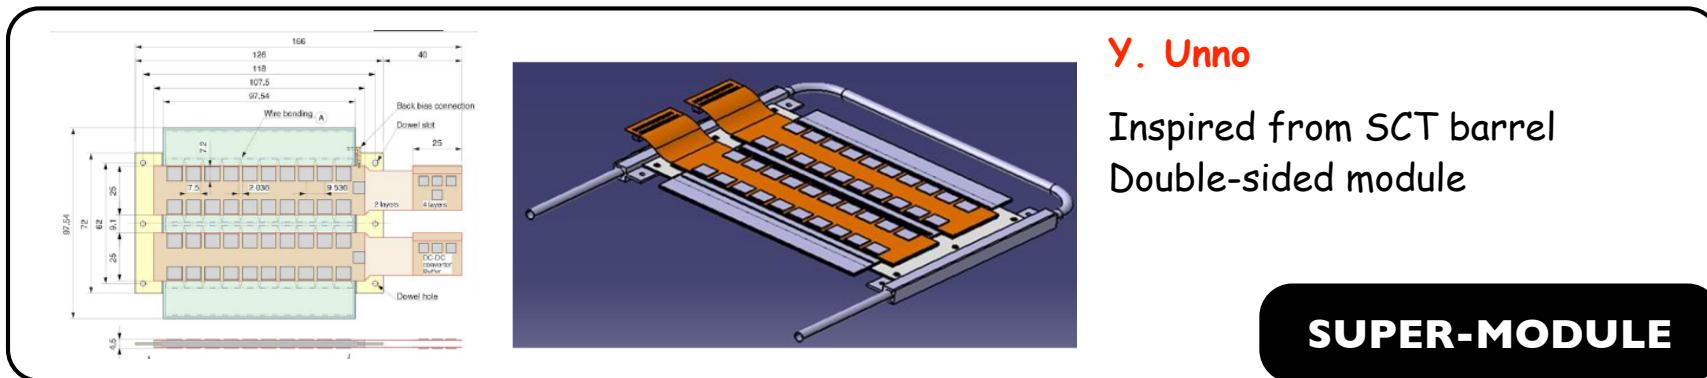

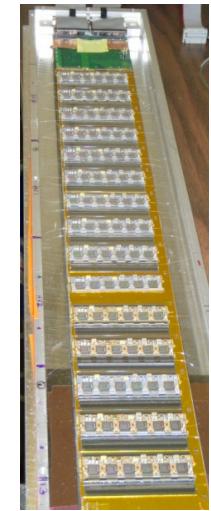

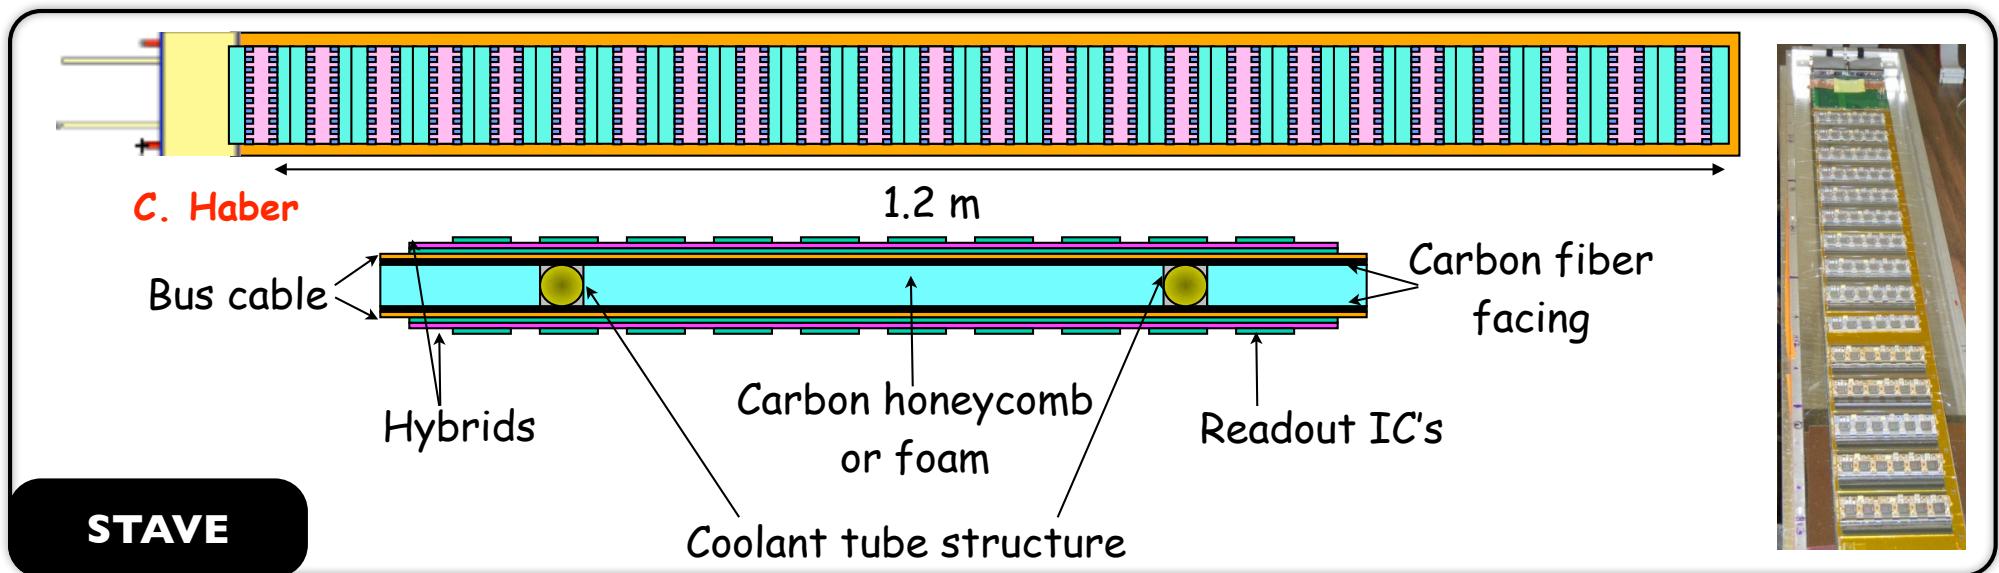

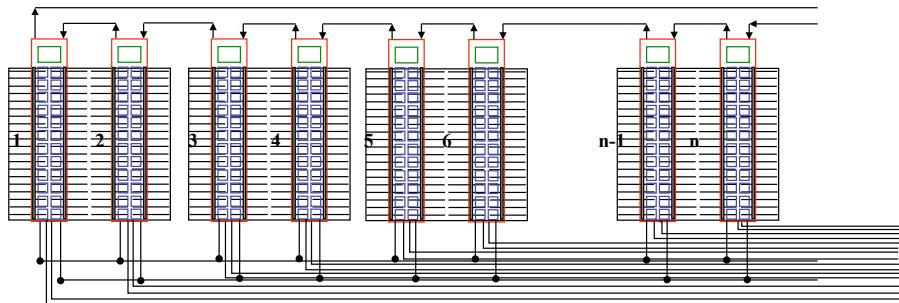

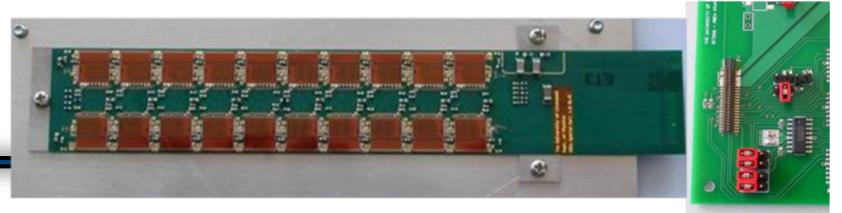

- Not "the" layout...
 - ▶ much work in progress
 - ◉ main purpose: help simulation studies to go-on
- Fixed barrel length
 - ▶ simpler from the engineering point of view than a semi-projective layout
 - ▶ Pixel barrel length ~ 1120 mm, Strip barrel length ~ 2350 mm
- 9-hit coverage $|n| < 2.5$

Barrel module integration

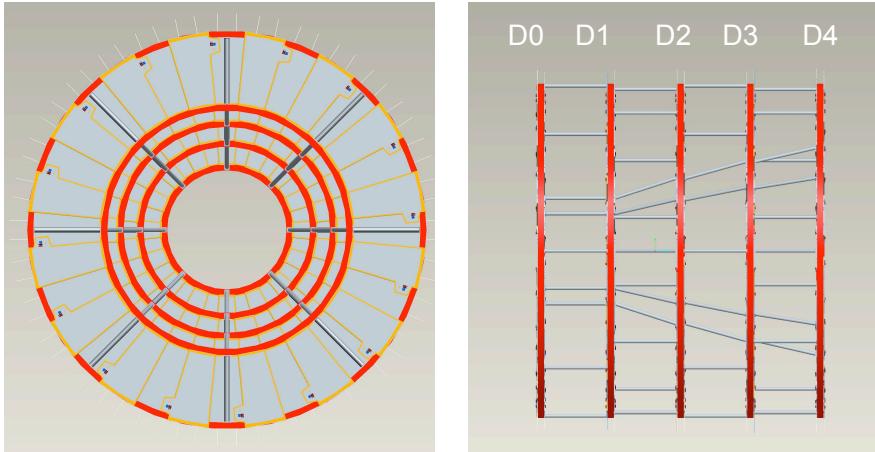

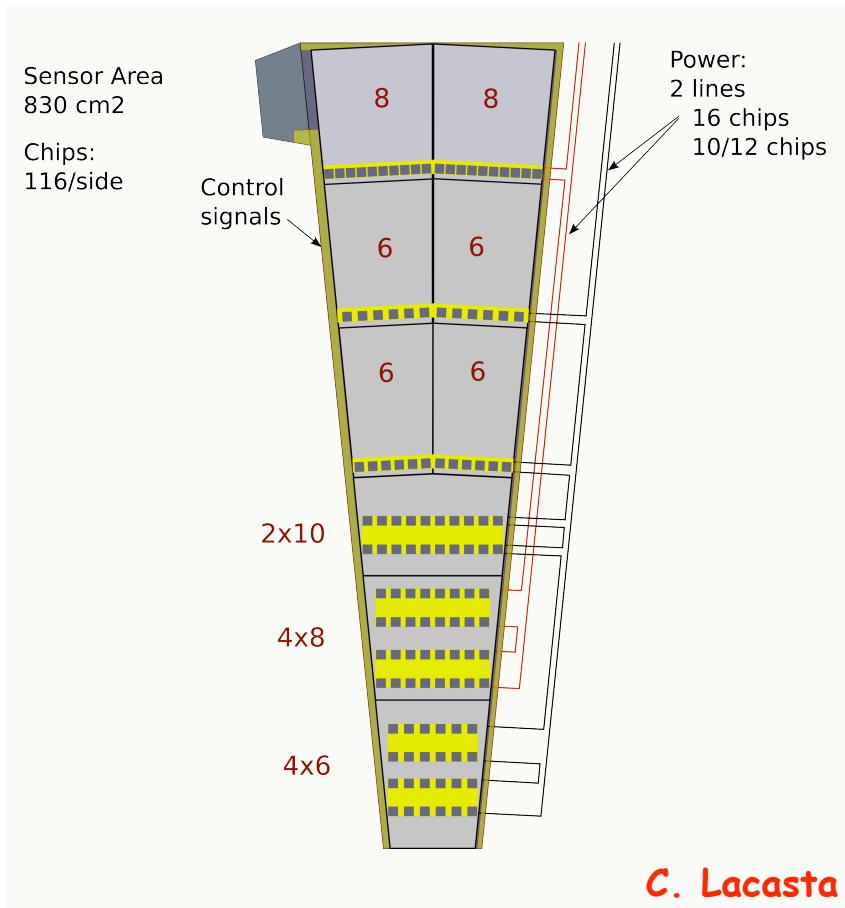

- Stave concept for barrel strip layers

- ▶ 24 hybrids (one side), 20 chips/hybrid arranged in two columns of 10. $V_{ABCN}=2.5V$, $I_{hyb}\sim 2.5 A$
- ▶ Powering schemes under study
 - Serial powering (saving in cables)
 - DC-DC conversion

Strip end-cap disks

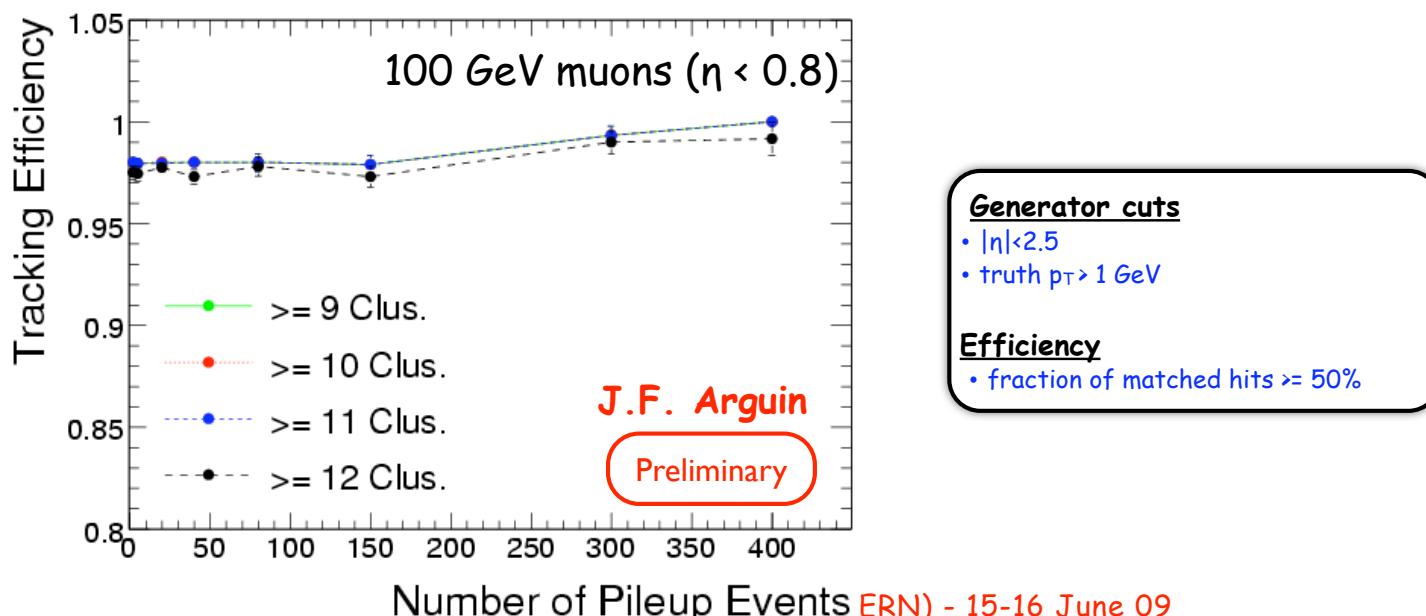

- 9 sensors, 6 different shapes
- Serial powering with 2 different lines
- For the moment, 8 different hybrids

- Sensors mounted on petals and disks made of petals
 - ▶ Coverage from R=340 mm to R=950 mm
 - ▶ 5 disks
 - ▶ 32 petals/disk
 - 4 different petals
 - ▶ Number of sensors/petal
 - max=18
 - min=12

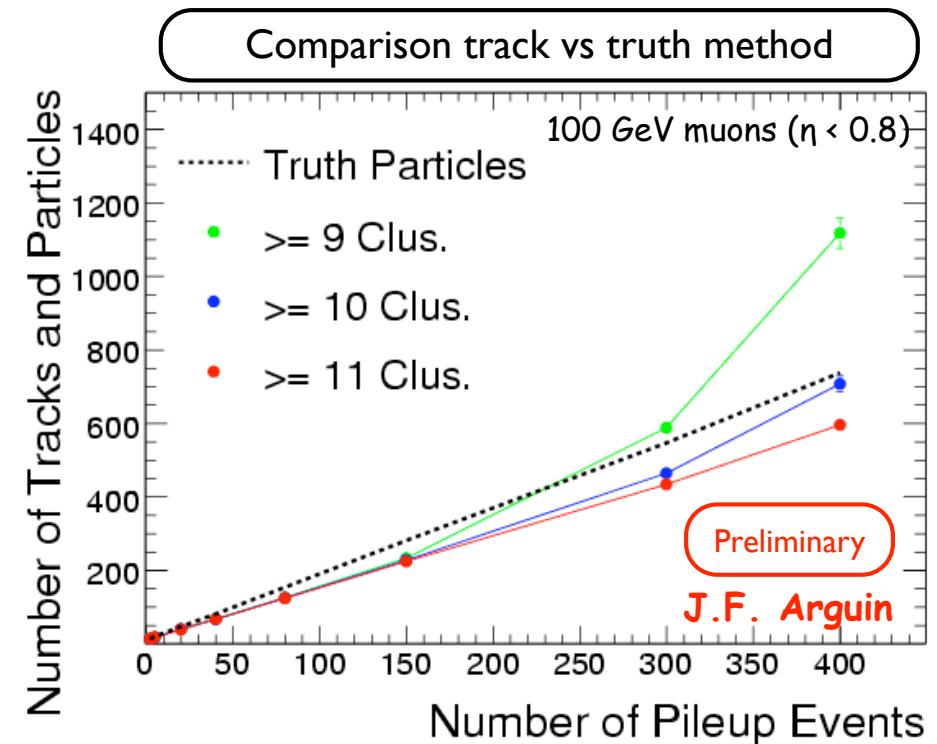

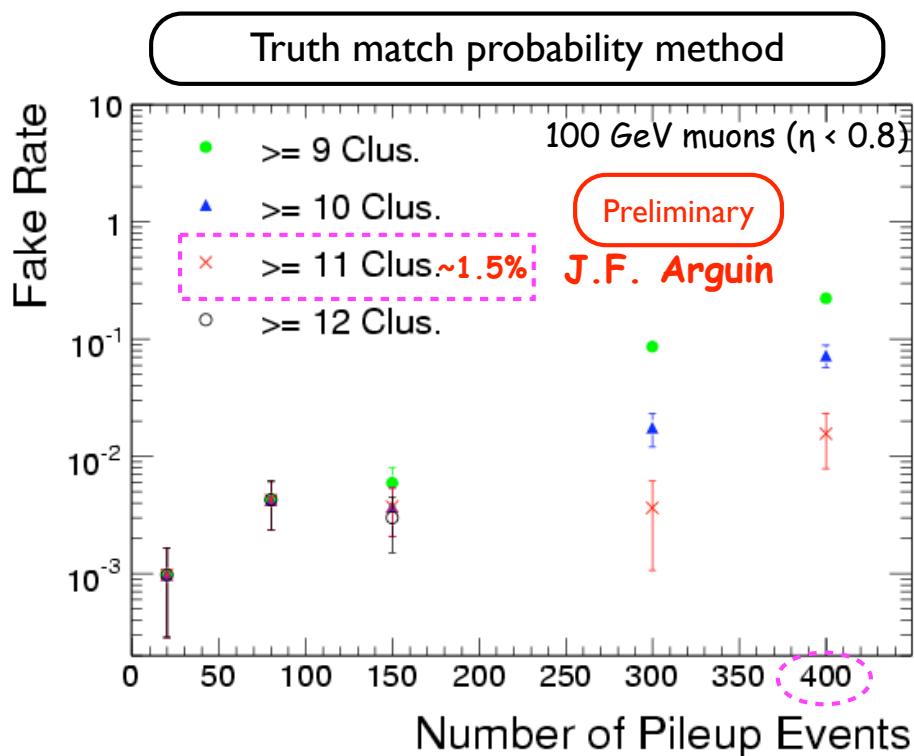

Some (preliminary) simulation results

- Track quality cuts as a starting point for SLHC studies
 - ▶ $|d_0| < 1 \text{ mm}$, d_0 corrected to the primary vertex position
 - ▶ $|z_0 - z_{\text{prim_vtx}}| \times \sin\theta < 2 \text{ mm}$ (loose B-tag cut at 10 mm)
 - ▶ $p_T > 1 \text{ GeV}$, $\chi^2/\text{ndf} < 5$
- Additional quality cuts on the number of Pixel/Strip hits and/or holes used to remove fakes
 - ▶ depending on layout → to be optimized
- Looking as well as optimizing CPU processing time
 - ▶ tracking tuning
 - constraining seeds
 - tune for heavy ion collisions will certainly help in this context

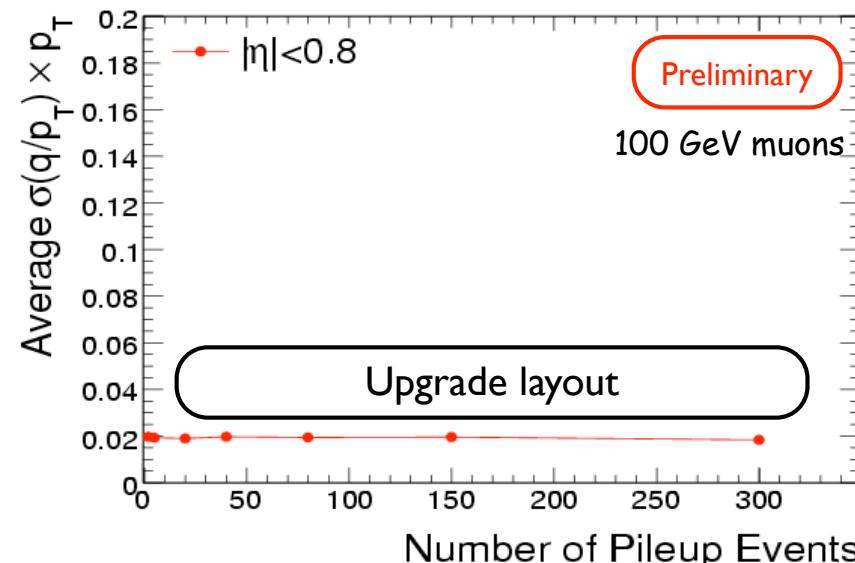

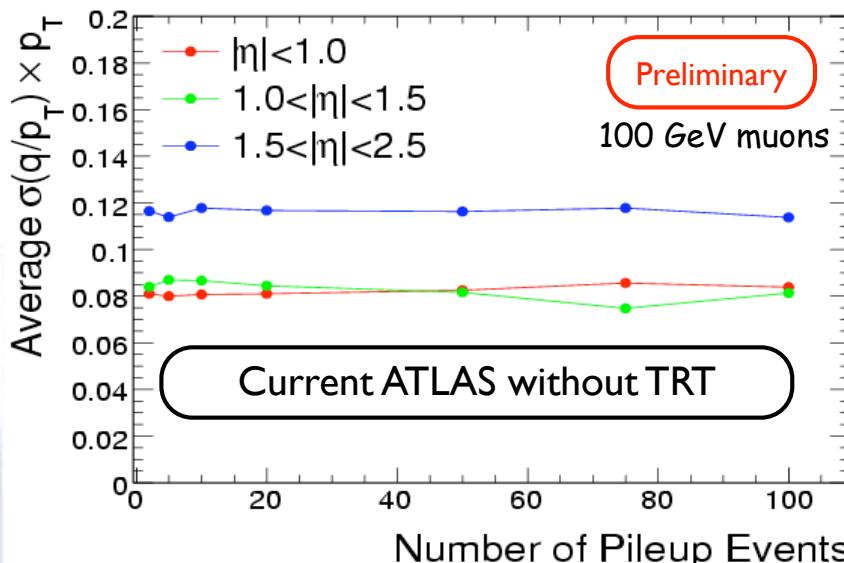

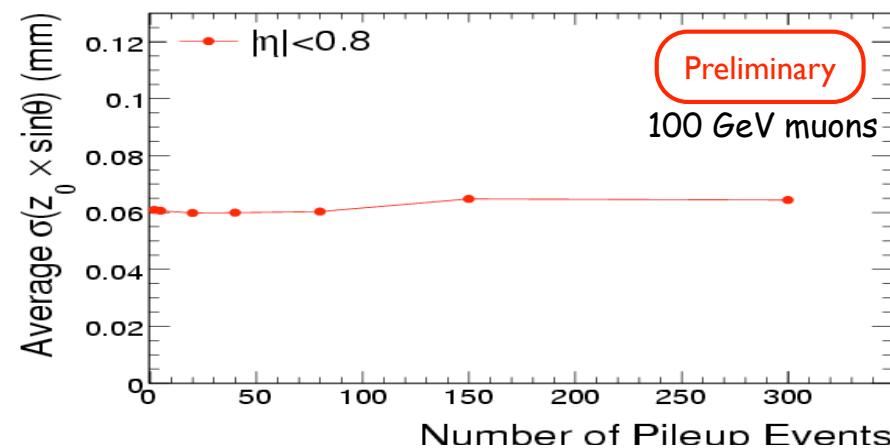

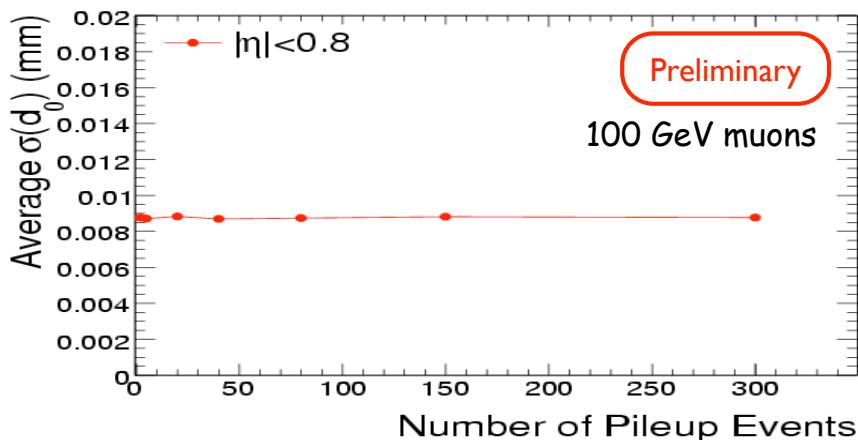

Fake rates

- Different methods to have an estimate of fake rate
 - ▶ truth match probability
 - tracks without associated truth or matched probability < 50%
 - ▶ comparison tracks vs truth particles
 - robust method independent of truth matching scheme

Resolution

- Comparison of working upgrade layout with current ATLAS (silicon-only, no TRT)
 - better impact parameter resolutions
 - much better q/p_T resolution ($\sim 2\%$)
 - even true if compared with the TRT in ($\sim 3\text{-}4\%$)

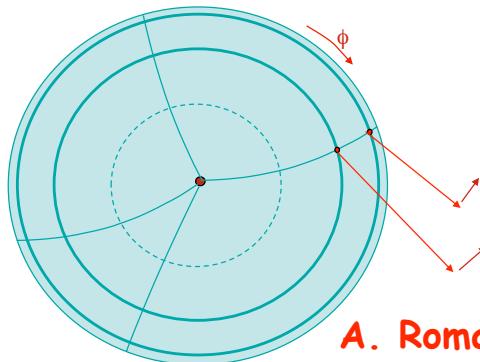

J.F. Arguin

Track triggers

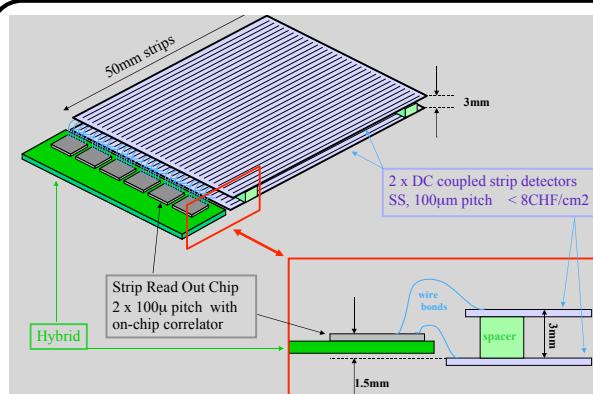

- Higher occupancy, challenge for L1 triggers
 - ▶ raise L1 rate → difficult to go above 100 kHz
 - ▶ rely on multi-object triggers → large fraction of lost events
 - ▶ possibility of raise p_T thresholds (~60 GeV single e/μ triggers) → impact on physics
- First level track trigger
 - ▶ matching with calo or muon detector objects
 - ▶ correlation of multiple trigger objects (leptons and/or jets) with same pp interaction in z

Gaseous detector

- 1.- Precision space points: X,Y
2.- Vector directions: η, Φ

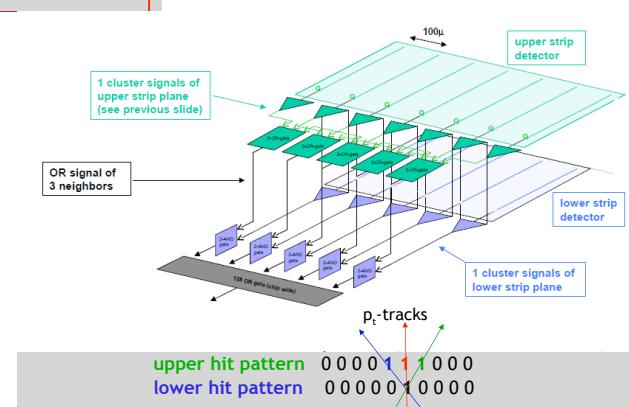

A. Romaniouk

W. Erdmann &
R. Horisberger

Two-in-one silicon
module design

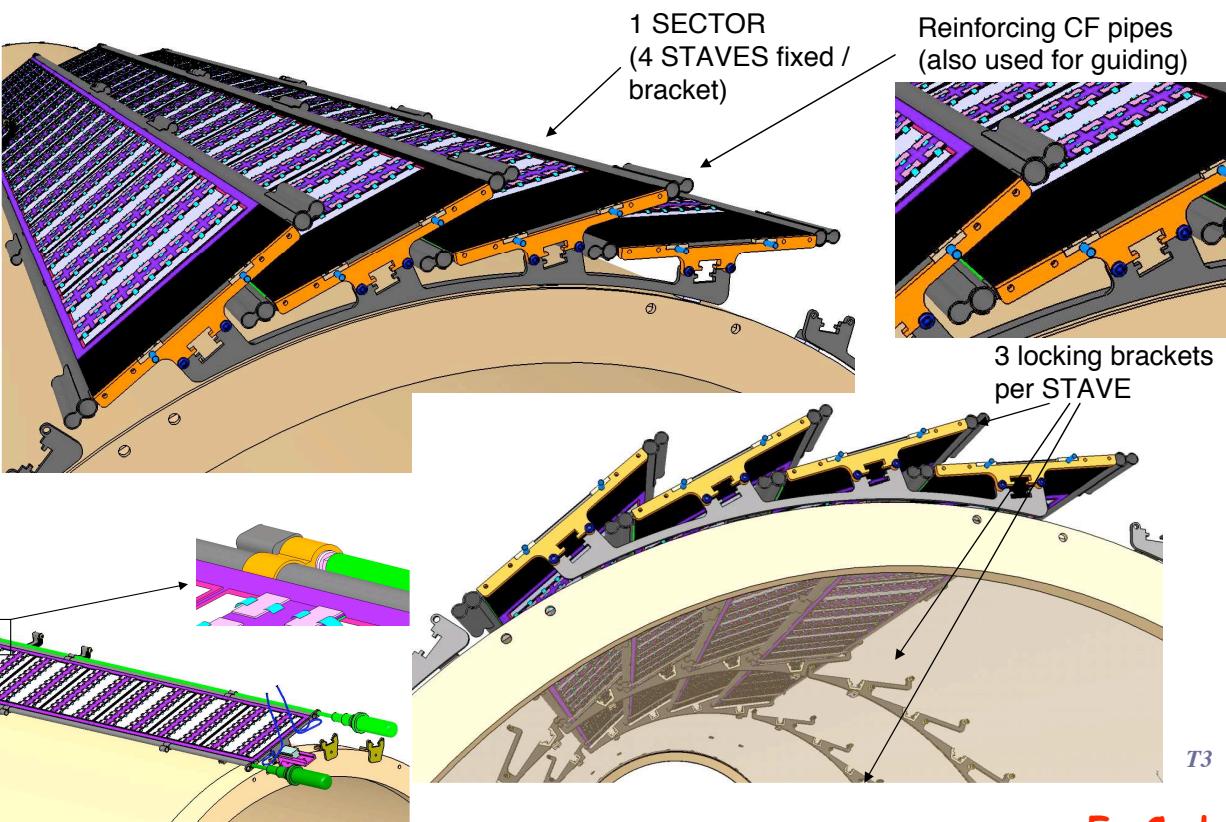

- 1.- strip cluster width detection
2.- 2-layers hit p_T correlation

Remarks concerning alignment

- Very rough estimate: 2.0×10^4 silicon strip-sensors
 - ▶ current SCT has 1.5×10^4 in ~4000 modules
 - ▶ significant increase in number of Pixel modules as compared with current Pixel detector
- Most probably, build tolerances will be less stringent
 - ▶ rely more on track-based software alignment
 - alignment based on sub-structures (in addition to other levels) will be definitely needed

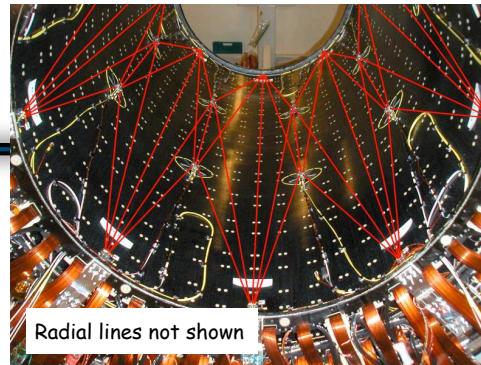

- Example: stave end-insertion concept
 - ▶ stave fixed to barrel at 3 points (brackets) along z
 - z_0 , z_{600} and z_{1200} (clamping position)
 - slight z-movement allowed for z_0 and z_{600}

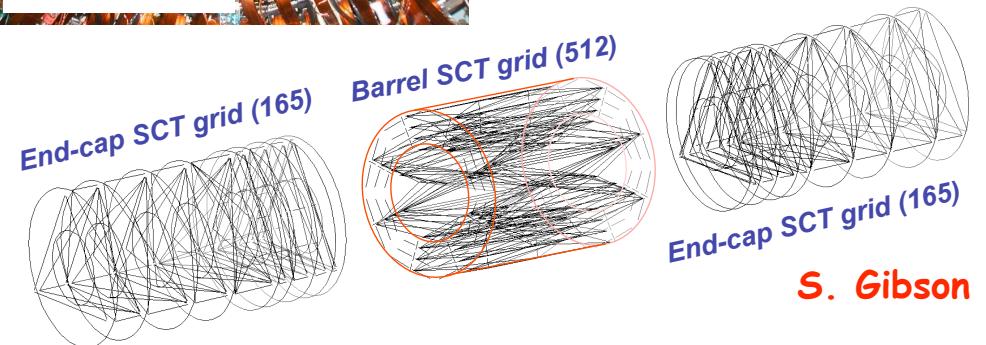

F. Cadoux

Hardware alignment

- Current ATLAS SCT barrel equiped with a laser alignment system
 - ▶ Frequency Scanning Interferometry (FSI)
 - ▶ 842 grid lines measured simultaneously
 - ▶ repeated grid measurements monitor shape changes of the SCT
 - ▶ Main functions
 - time dependent corrections
 - improve alignment of weak modes
- It would be very helpful for a better upgraded layout understanding to know if a hardware alignment system is needed
 - ▶ if FSI shows significant movements on a time-scale basis faster than track-based alignment can correct for → strong indication of the need to design a harware-based alignment system
 - ▶ importance of kinematic mounts to minimise internal distortions ?
 - ▶ if needed:
 - monitoring structures or silicon sensors themselves ?
 - ❖ for the latter option, such an alignment system need to be designed NOW !!
 - ▶ need solid data to base a decision !!

Distance measurement between grid nodes precise < 1 μm

Decision in favour or against a new hardware alignment system is the most urgent of all alignment questions for the design of an upgraded ID layout

Summary

- Recall that the ID upgrade program starts with B-layer replacement in 2013
 - ▶ but no major differences with the existing Pixel detector
- For Phase II, new ATLAS ID required
 - ▶ Most of what've presented is "work in progress"
 - layout not decided yet
 - ❖ although clear that will be silicon-only (prohibitive TRT occupancies)
 - numbers very preliminary, simulation studies on-going to decide which are the best options
 - ❖ playing with number of layers, tilt angles, etc.
- From the alignment point of view
 - ▶ major concern now is to know if need to implement a hardware alignment system
 - impact on layout studies, to be addressed asap...
 - ▶ number of silicon modules will definitely increase with respect current ATLAS ID
 - once the alignment of the present detector is understood and under control, would be required to think in how to align a larger system
 - ❖ 64 bits technology mature enough (to say the least)
 - ❖ new alignment algorithms ?
 - ❖ tracking tuning to deal with huge pile-up...
 - ▶ will probably rely more on track-based alignment
- Certainly, the work spent in the present detector will pay-off in the future !!
