

# What can we learn about CR acceleration from observations?

HAMILTON  
2005

Luke Drury  
Dublin Institute for Advanced Studies

HAMILTON  
2005

Not as much as we would  
like, but still quite a lot!  
Much recent progress...

# Evidence from observations

HAMILTON  
2005

Spectrum (energy/rigidity)

Composition

Isotropy

Spatial distribution

Signatures of sources

HAMILTON  
2005

# Warning!

Spectrum observed is **NOT** source spectrum!

Composition is **NOT** source composition!

Angular distribution does **NOT** reflect source directions!

**Propagation!**  
(and modulation)

HAMILTON  
2005

# Spectrum

Very well described by power-law from below a GeV to 100TeV per nucleon - index about 2.7 - then the "knee" etc.

Low energy spectrum below 100MeV only poorly constrained.

Propagation has steepened spectrum, true source spectrum in range 2.0-2.3

HAMILTON  
2005

Power-law over five or six decades  
with no obvious feature => scale  
independent acceleration process.

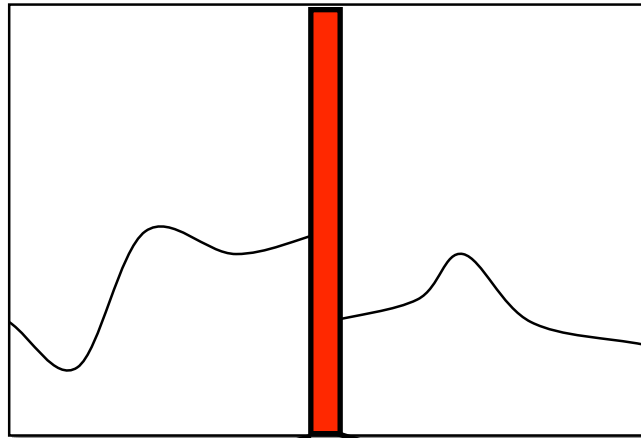

Shock acceleration is essentially only  
theory going (pulsars, reconnection  
remain possibilities, but no quantitative  
theory).

Nonlinear shock acceleration is almost  
certainly important....

HAMILTON  
2005

Outer scale  
Astrophysics

Precursor

Subshock

Intermediate scales  
Shock acceleration theory

Inner scale  
Plasma physics  
**Injection!**

HAMILTON  
2005

From P. Blasi, 2002

HAMILTON  
2005

Strong “filtering” needed to throttle back injection from plasma collisionless shock structure to shock acceleration on intermediate scales => easier to inject high rigidity species => expect more heavy ions, very few electrons.

HAMILTON  
2005

# Composition

Very well determined at GeV/nucleon energies (even isotopic data in many cases - radioactive ages, K-capture)

Spectra of spallation secondaries =>

Energy dependent propagation

Harder source spectra

No such constraints at higher energies (but watch this space...).

MEYER, DRURY, & ELLISON

HAMILTON  
2005

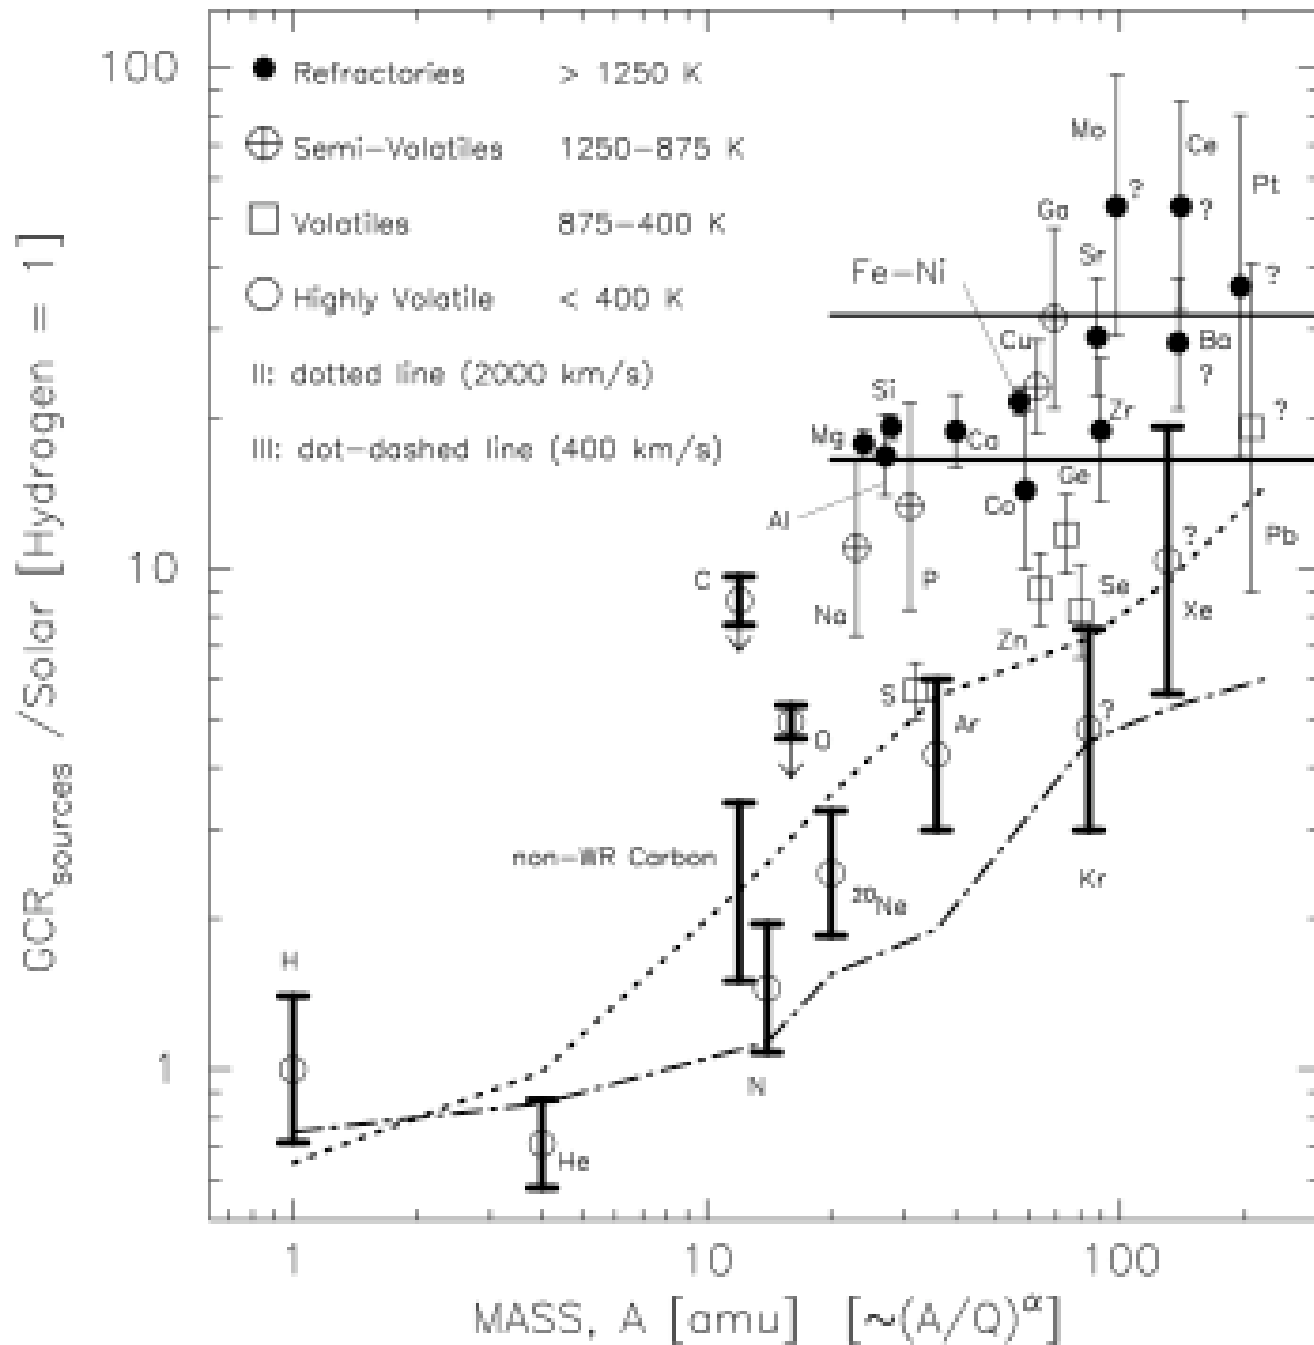

Heavy elements are over-abundant, but not obviously any simple  $A/Q$  effect.

But in ISM Fe, Ca, Al, Si etc are almost entirely in the form of dust grains...

Small dust grains behave like very heavy ions when charged...

HAMILTON  
2005

HAMILTON  
2005

# Isotropy

CRs below the “knee” are isotropic to about  $10^{-4}$

- => much scattering by magnetic fields
- => large confinement volume
- => no nearby active sources
- => multiple sources

HAMILTON  
2005

# Spatial distribution

GeV gamma-ray data from EGRET =>  
rather smooth distribution of CRs  
throughout the Galactic disc. Possibly  
too smooth and extended (but comes  
back to propagation models...). Probably  
related to extreme isotropy...

HAMILTON  
2005

All indirect evidence, but shock acceleration in SNRs looks like best bet for the GCRs below the “knee”.

What about direct evidence?

Radio synchrotron => electron acceleration to GeV energies

HAMILTON

HAMILTON  
2005

Spectrum is close to  $E^{-2}$  from 1 to 10 TeV.

Very good correlation between X-rays and TeV emission (surprisingly good!).

Unambiguous evidence for acceleration of charged particles to  $10^{14}$  eV.

HAMILTON  
2005

But could be just accelerated electrons..

Another cosmic conspiracy -  $10^{14}$ eV electrons IC scattering the CMB make gammas at  $10^{13}$ eV and  $10^{14}$ eV  
protons also make gammas at the same energy by neutral pion production.

HAMILTON  
2005

Crucially depends on the magnetic fields.

Growing evidence for substantially  
enhanced fields in young SNRs

Generally favours hadronic models, but  
jury is still out.

# γ-ray emission from the supernova remnant Cassiopeia A

1006

XMM

1006

1006

KASCADE

KASCADE

(KASCADE, 1006, XMM, XMM)

1006A

1006A

The image shows the X-ray emission from Cassiopeia A, which is a supernova remnant. The emission is primarily in the soft X-ray band, with a peak around 0.5 keV. The emission is distributed throughout the shell, indicating a high degree of mixing and homogeneity. This is consistent with the model of a rapidly expanding supernova remnant that has swept up a significant amount of interstellar material.

1006: KASCADE emission 95, 1006g emission, B, b emission, F; 1006: Hw 1006g emission 2; KASCADE: 1006 - 1006; 1006 4; 1006A: G 1006 1, 1006& 1006 1006

The emission is distributed throughout the shell, indicating a high degree of mixing and homogeneity. This is consistent with the model of a rapidly expanding supernova remnant that has swept up a significant amount of interstellar material.

HAMILTON  
2005

Sharp narrow rims seen in non-thermal X-rays are most easily explained by rapid synchrotron cooling of electrons in strong magnetic field of order 0.1mG

If fields are 30-100 times larger than standard ISM fields, can accelerate protons to 30-100 times higher energies.

Possible evidence for Bell-Lucek process?

HAMILTON  
2005

# Conclusions

Shock acceleration in SNRs with some magnetic field amplification seems to be able to explain almost all observations of CRs below the “knee” - but there are the HESS unidentified sources also!
