#### SPEECH DELIVERED BY PROFESSOR NIELS BOHR

ON THE OCCASION OF THE INAUGURATION OF THE CERN PROTON SYNCHROTRON

ON 5 FEBRUARY, 1960

Press Release PR/56 12 February, 1960

It may perhaps seem odd that apparatus as big and as complex as our gigantic proton synchrotron is needed for the investigation of the smallest objects we know about. However, just as the wave features of light propagation make huge telescopes necessary for the measurement of small angles between rays from distant stars, so the very character of the laws governing the properties of the many <u>new elementary particles</u> which have been discovered in recent years, and especially their transmutations in <u>violent collisions</u>, can only be studied by using <u>atomic particles</u> <u>accelerated to immense energies</u>. Actually we are here confronted with most challenging problems at the border of physical knowledge, the exploration of which promises to give us a deeper understanding of the laws responsible for the very existence and stability of matter.

All the ingredients are there: we need high energy particles collinding in large accelerators to study the matter constituents and their interactions laws. **Does it look like the LHC ?** 

Small detail... Bohr was not completely right, the "new" elementary particles are not elementary but mesons, namely formed by quarks

# PS will be 50 in November ...

High energy: PS 26 10<sup>9</sup> eV (GeV) LHC 7 10<sup>12</sup> eV (TeV)

Large accelerators: PS ~628 m (cir.) LHC ~ 27 km (cir.)

Colliding: PS fix target exp. LHC real collider

### **Interactions laws:**

PS discovery neutral currents LHC hopefully the Higgs (+)

Why high energies? Why large accelerators? Colliding means what?

# The right instrument for a given dimension

Wavelength of probe radiation should be smaller than the object to be resolved

 $\lambda \ll \frac{h}{p} = \frac{hc}{E}$ 

Object	<mark>Size</mark>	Energy of Radiation
Atom	10⁻⁰ m	0.00001 GeV (electrons)
Nucleus	10⁻⁴ m	0.01 GeV (alphas)
Nucleon	10⁻⁵m	0.1 GeV (electrons)
Quarks	?	> 1 GeV (electrons)
Quarks	2	> 1 GeV (electrons)

Radioactive sources give energies in the range of MeV

Need accelerators for higher energies.

### The typical energy of our life is eV So, how we can reach the energy/dimension of the big bang?

# Interlude: a brief recall of energy scales

- WARNING: for purists or non-experts: Energy, Masses and Momentum have different units, which turn to be the same since c (speed of light) is considered equal to one.
  - Energy[GeV], Momentum [GeV/c], Masses [GeV/c<sup>2</sup>] (Remember golden rule, E=mc<sup>2</sup> has to be true also for units...)
- Just an as a rule of thumb: 0.511 MeV/c<sup>2</sup> (electron mass) corresponds to about 9.109 10<sup>-31</sup> kg

```
An Example about energy scales: my cellular phone battery.

Voltage: 3.7 V → 3.7 eV energy of e- from one

electrode to the other

Height: 4.5 cm

proton mass ~ I I0<sup>9</sup> eV

To accelerate an electron to an energy equivalent to a proton mass:

I GeV/3.7 eV = 270 270 270 batteries
```

270 270 270 batteries \* 0.045 m ~ 12 000 000 m

12 000 000 m ~ THE EARTH DIAMETER

Obviously one has to find a smarter way to accelerate particles to high energies instead of piling up cellular phone batteries ....

# Basically we want to bring you ...

### from nearly a bottle of hydrogen

### to a little bit before this

through the history of this science, the theory, the technological challenges and the applications

### **CERN** accelerator complex overview

### Matter constituents and interaction laws, the actors of our play

The particle drawings are simple artistic representations

We need enough energy to produce directly the different particles, at least their mass

We need enough intensity (i.e. particle interactions) to produce enough particles

# History/Energy line vs discovery

Higgs and super-symmetry ? Or something else maybe 10,000 THE ENERGY FRONTIER (GeV) (Discoveries) LHC 1000 Hadron Colliders Constituent Center-of-Mass Energy (top quark) Tevatron EP II (W<sup>±</sup>,Z bosons) SppS 100 (Ny=3) RISTAN PETRA, PEP (gluon) ISR. 10 EAR II (charm guark, τ lepton) Colliders e+e-1960 1970 1980 1990 2000 Year of First Physics 9-93 8047A608

Behind the history plot is hidden the technological development required for each step

Obs: you can notice different particle species used in the different colliders electron-positrons and hadron colliders (either p-p as Tevratron, p-p as LHC)

# Different approaches: fixed target vs collider

#### Fixed target

Storage ring/collider

 $E_{CM} = \sqrt{2(E_{beam}mc^2 + m^2c^4)} \quad << \quad E_{CM} = 2(E_{beam} + mc^2)$ 

# ISR: first proton-proton collider

# History/Energy line vs discovery

Higgs and super-symmetry ? Or something else maybe 10,000 THE ENERGY FRONTIER (GeV) (Discoveries) LHC 1000 Hadron Colliders Constituent Center-of-Mass Energy (top quark) Tevatron EP II (W<sup>±</sup>,Z bosons) SppS 100 (Ny=3) RISTAN PETRA, PEP (gluon) ISR. 10 EAR II (charm guark, τ lepton) Colliders e+e-1960 1970 1980 1990 2000 Year of First Physics 9-93 8047A608

Behind the history plot is hidden the technological development required for each step

Obs: you can notice different particle species used in the different colliders electron-positrons and hadron colliders (either p-p as Tevratron, p-p as LHC)

### The proper particle for the proper scope

Electrons (and positrons) are (so far) point like particles: no internal structure

 $(e^{-}) \rightarrow \times \leftarrow (e^{+})$ 

The energy of the collider, namely two times the energy of the beam colliding is totally transferred into the collision

Ecoll = Ebl + Eb2 = 2Eb = 200 GeV (LEP)

Pros: the energy can be precisely tuned to scan for example, a mass region. Precision measurement (LEP)

convenient to use electron because of too lower than the accelerator energy high <u>syncrotron radiation</u> (last lecture)

Protons (and antiprotons) are formed by quarks (uud) kept together by gluons

The energy of each beam is carried by the proton constituents, and it is not the entire proton which collides, but one of his constituent

#### Ecoll < 2Eb

<u>Pros:</u> with a single energy possible to scan different processes at different energies. Discovery machine (LHC)

<u>Cons</u>: above a certain energy is no more <u>Cons</u>: the energy available for the collision is

# Synergy between accelerators and particle physics

- First prove that the antiproton life time has to be comparable to the one of the protons (from CPT theorem) came from the ICE storage ring in 1978 (ICE does not exists anymore...)
  - Antiproton lifetime before ICE experiment: 1.2 10<sup>-4</sup> s
  - About 240 antiprotons stored for 85 h, the final intensity of about 80 antiprotons due to Coulomb scatting on residual gas.
    - Estimated final lifetime: about 32 h in the rest frame.

 This experiment also opened the era of the p-p collider which required storage time of about 24 h.

See Phys. Lett. 78B, I pag. 174, you will find 2 nobel prices in the author list

# How an accelerator works ?

**F**<sub>B</sub>

# How to get protons: duoplasmatron source

### How to get antiprotons

# Cockroft-Walton. Old CERN proton pre-injector

### CERN: 750 kV, used until 1993

Bits an pieces are in the garden outside the Microcosm

# Main limitation

Main limitation: electric discharge due to too high Voltage. Maximum limit: 1 MV

Limit set by Paschen law: the breaking Voltage between two parallel electrodes depends only on the pressure of the gas between the electrodes and their distance

Low pressure: gas not too dense, long mean average path of High pressure: dense electrons gas, large Voltage needed for gas

ionisation

# Van De Graaf electrostatic generator (1928)

MIT Museum all rights reserved

# Tandem

Current applications:

- a) Low energy injector for lons Still in use at Brookeven (US) as injector for Cu and Au ions
- b) Compact system for "other uses" Dating of samples at Louvre.

Application of Lou

<u> http://</u>

# Wideroe linac: the first linear accelerating structure

Obs: the drift tube length has to increase because particles are not yet relativistic. To an energy increase corresponds a speed increase, and the particle has to travel more in the shielded region to be in phase with the accelerating field.

Main limitation: after a certain energy, the length of the drift tube is too long. The RF frequency has increase to some 10 MHz, need to enclose the structure in a resonator to avoid field losses.

# Alvarez drift tube linac

**Linac** composed by **drift tubes** interleaved by **acceleration gaps** as Wideroe linac, but field generated in a **resonant cavity**. The frequency of the field can go up to 200 MHz.

Currently we have two Linacs at CERN with Alvaretz structure, for protons and ions.

Inner structure of Linac I (Alvarez type). The drift tubes are supported on stems, through which the current for the quadrupole magnets (located inside the tubes) and the cooling water are supplied. Linac I accelerated

protons to 50 MeV.

See lecture for linear collider

# Cyclotron

Particle source located in a vertical B field near the center of the ring

Electrical (E) RF field generated between two gaps with a fixed frequency

Particles spiral while accelerated by E field every time they go through the gap

$$Ep = \frac{1}{2} \frac{e^2}{m_0} BR_{max}^2$$

#### Max energy for protons: 20 MeV

Main limitations:
I) not working for relativistic particles, either high energy or electrons
2) B field at large radius not vertical

Invented by Lawrence, got the Noble prize in 1939

# The first cyclotron and the Berkeley one

# Betatron (invented by Wideroe in 1923)

### **Betatron**

#### Betatron used for xray generation

#### Betatron from wikipedia

# Synchrotron (1952, 3 GeV, BNL)

New concept of circular accelerator. The magnetic field of the bending magnet varies with time. As particles accelerate, the B field is increased proportionally. The frequency of the RF cavity, used to accelerate the particles has also to change. Particle rigidity:  $B\rho =$ eB = B(t) magnetic field from the Deflection electrodes bending magnets . p = p(t) particle momentum varies C-type gap to outside Internal by the <u>RF cavity</u> target and Inflector extraction electric charge e Analysing **RF** station magnet constant radius of curvature ρ Electrostatic injector New magnetic elements for injection and extraction. Weak focusing machine: no quadrupoles yet Bending strength limited by used technology to max  $\sim I T$  for room temperature conductors, Strong focusing machine, using quadrupoles, were

proposed in 1952

### The last generation of synchrotrons: strong focusing machine

Dipoles are interleaved with quadrupoles to focus the beam. Quadrupoles act on charged particles as lens for light. By alternating focusing and defocusing lens (Alternating Grandient quadrupoles) the beam dimension is kept small (even few mum<sup>2</sup>).

# A synchrotron in a view: LEIR (Low Energy Ion Ring)

# More in tomorrow lecture ...

# The story of accelerator vs energy

Early days only fixed target: easier conception of the accelerator, lower energy, simpler experimental setup

Interlude: a brief recall of energy scales and kinematic relationships  $m = \sqrt{E^2 - p^2} \qquad \beta = \frac{v}{c} \qquad \gamma = \frac{1}{\sqrt{1 - \beta^2}}$ 

- WARNING: for purists or non-experts: Energy, Masses and Momentum have different units, which turn to be the same since c (speed of light) is considered equal to one.
  - Energy [GeV], Momentum [GeV/c], Masses [GeV/c<sup>2</sup>] (Remember golden rule, E=mc<sup>2</sup> has to be true also for units...)
- Just an as a rule of thumb: 0.511 MeV/c<sup>2</sup> (electron mass) corresponds to about 9.109 10<sup>-31</sup> kg

WARNING: the letters  $\beta \gamma$  will be used later with a different meaning, as TWISS or OPTICS parameters which have nothing to do with relativistic kinematics.

# Why particle accelerators ?

- Why accelerators: need to produce under <u>controlled conditions</u> HIGH INTENSITY, at a CHOSEN ENERGY particle beams of GIVEN PARTICLE SPECIES to do an EXPERIMENT
- An experiment consists of studying the results of colliding particles either onto a fixed target or with another particle beam.

#### The cosmo is already doing collisions with different mechanisms:

while I am speaking about 66 10<sup>9</sup> particles/cm<sup>2</sup>/s are traversing your body, with this spectrum before being filtered by the atmosphere.

The universe is able to accelerate particles up to 10<sup>6</sup> MeV protons (See cosmology lectures)
