

Towards Neutrino oscillations without mass diagonalization nor Lagrangians

QFT - F

(on-shell methods)

- QFT = a very successful framework
- Still, there are some drawbacks:
 - Lorentz invariance forces us to work with redundant fields (gauge redundancy)
 - Fields redefinitions are sometimes needed to make the physics manifest (e.g. $\mathcal{L} = \frac{1}{2}(\partial\phi)^2 - \frac{m^2}{2}\phi^2 + \frac{2}{\Lambda}\phi(\partial\phi)^2 - \frac{m^2}{\Lambda}\phi^3 + \frac{2}{\Lambda^2}\phi^2(\partial\phi)^2 - \frac{m^2}{2\Lambda^2}\phi^4$ is a free theory!)
 - In EFTs some work is needed to find a basis of independent operators

 - Fields redefinitions are sometimes needed to make the physics manifest (e.g. $\mathcal{L} = \frac{1}{2}(\partial\phi)^2 - \frac{m^2}{2}\phi^2 + \frac{2}{\Lambda}\phi(\partial\phi)^2 - \frac{m^2}{\Lambda}\phi^3 + \frac{2}{\Lambda^2}\phi^2(\partial\phi)^2 - \frac{m^2}{2\Lambda^2}\phi^4$ is a free theory!)
 - In EFTs some work is needed to find a basis of independent operators

Can we bypass these drawbacks? YES!

- In the 1960's QFT and EFT techniques put a stop to the S-matrix program
compute directly amplitudes from first principles
- In the 2010's we saw a resurgence of the S-matrix program

Idea

- Back to the basics: quantum particle = irrep of the Poincaré group
- The irreps of Poincaré are induced by the LITTLE GROUP (LG) irreps
 - For massive particles (in $d = 4$) \longrightarrow SO(3)
 - For massless particles (in $d = 4$) \longrightarrow U(1) (ignoring continuous-spin)
- Amplitude $\mathcal{A} = \langle f | T | i \rangle$ inherits the LG transformations:

$$\mathcal{A} \rightarrow \prod_{a=i,f} D_a \mathcal{A}$$

- **Whole point:** determine \mathcal{A} solely from its transformation under the LG
- There is no notion of quantum field nor Lagrangian!

Technical parenthesis:

- LG transformations are complicated functions of momenta (not easy to work with)
- HOWEVER: they become simple using the $SO(1,3) \leftrightarrow SL(2,\mathbb{C})$ correspondence \Rightarrow use **spinor variables**!

Massless particles

- 3-points amplitudes COMPLETELY FIXED by helicity
- Important results:
 - GR and YM as the unique consistent theories of massless self-interacting spin-2 and spin-1 particles
 - Anomaly condition recovered without worrying about the path integral measure
 - higher points amplitudes can be determined recursively from lower-point amplitudes (using polology)
 - (High energy) QCD phenomenology simplified!

Massive particles

- LG a bit more complicated, amplitudes a bit more complicated
- Important results: Yang theorem, massive particles with $s > 2$ cannot be elementary
- The Higgs mechanism can be recovered completely bottom-up
- The result is automatically valid at ALL ORDERS in a $1/\Lambda$ expansion!
(because we obtain “kinematic structures” with the right transformations under the LG)

What has been done for the SM

- The SM on-shell amplitude has been written a couple of years ago, but the couplings were put “by hand”
- BUT...we know that not all couplings are equivalent in the SM: some involve unitary matrices, and these constitute a prediction of the theory

OUR QUESTION 1

The SM predicts UNITARY CKM and PMNS

can we obtain this result without mass
diagonalization?

Start with the 3-point amplitude

$$\mathcal{A} = \underbrace{\frac{y_L^{ij}}{M} \langle \mathbf{1}_i \mathbf{3} \rangle \langle \mathbf{2}_j \mathbf{3} \rangle}_{\boxed{\bar{e}_R \sigma^{\mu\nu} \nu_L W_{\mu\nu}^-}} + \underbrace{\frac{g_L^{ij}}{m_W} \langle \mathbf{1}_i \mathbf{3} \rangle [\mathbf{2}_j \mathbf{3}]}_{\boxed{\text{SM}}} + \underbrace{\frac{g_R^{ij}}{m_W} [\mathbf{1}_i \mathbf{3}] \langle \mathbf{2}_j \mathbf{3} \rangle}_{\boxed{\bar{e}_R \gamma^\mu \nu_R W_\mu^-}} + \underbrace{\frac{y_R^{ij}}{M} [\mathbf{1}_i \mathbf{3}] [\mathbf{2}_j \mathbf{3}]}_{\boxed{\bar{e}_L \sigma^{\mu\nu} \nu_R W_{\mu\nu}^-}}$$

UV origin depend on the Majorana/Dirac ν nature
(at $d = 6$ for Dirac , at $d = 7$ for Majorana)

Start with the 3-point amplitude

$$\mathcal{A} = \underbrace{\frac{y_L^{ij}}{M} \langle \mathbf{1}_i \mathbf{3} \rangle \langle \mathbf{2}_j \mathbf{3} \rangle}_{\boxed{\bar{e}_R \sigma^{\mu\nu} \nu_L W_{\mu\nu}^-}} + \underbrace{\frac{g_L^{ij}}{m_W} \langle \mathbf{1}_i \mathbf{3} \rangle [\mathbf{2}_j \mathbf{3}]}_{\boxed{\text{SM}}} + \underbrace{\frac{g_R^{ij}}{m_W} [\mathbf{1}_i \mathbf{3}] \langle \mathbf{2}_j \mathbf{3} \rangle}_{\boxed{\bar{e}_R \gamma^\mu \nu_R W_\mu^-}} + \underbrace{\frac{y_R^{ij}}{M} [\mathbf{1}_i \mathbf{3}] [\mathbf{2}_j \mathbf{3}]}_{\boxed{\bar{e}_L \sigma^{\mu\nu} \nu_R W_{\mu\nu}^-}}$$

taking the massless limits we can match to the massless amplitude

+

in the massless limit we are free to redefine the states using flavor transformations

$$|\nu_i(\mathbf{p}, h)\rangle \rightarrow (U_\nu^*)_{ji} |\nu_j(\mathbf{p}, h)\rangle, \quad |\bar{e}_i(\mathbf{p}, h)\rangle \rightarrow (U_e)_{ji} |\bar{e}_j(\mathbf{p}, h)\rangle$$

Start with the 3-point amplitude

$$\mathcal{A} = \underbrace{\frac{y_L^{ij}}{M} \langle \mathbf{1}_i \mathbf{3} \rangle \langle \mathbf{2}_j \mathbf{3} \rangle}_{\boxed{\bar{e}_R \sigma^{\mu\nu} \nu_L W_{\mu\nu}^-}} + \underbrace{\frac{g_L^{ij}}{m_W} \langle \mathbf{1}_i \mathbf{3} \rangle [\mathbf{2}_j \mathbf{3}]}_{\boxed{\text{SM}}} + \underbrace{\frac{g_R^{ij}}{m_W} [\mathbf{1}_i \mathbf{3}] \langle \mathbf{2}_j \mathbf{3} \rangle}_{\boxed{\bar{e}_R \gamma^\mu \nu_R W_\mu^-}} + \underbrace{\frac{y_R^{ij}}{M} [\mathbf{1}_i \mathbf{3}] [\mathbf{2}_j \mathbf{3}]}_{\boxed{\bar{e}_L \sigma^{\mu\nu} \nu_R W_{\mu\nu}^-}}$$

$$\begin{aligned} \frac{g_L}{m_W} &\longrightarrow \frac{U_\nu^\dagger g_L}{m_W} \longrightarrow \frac{U_\nu^\dagger g_L U_e}{m_W} \longrightarrow U_\nu^\dagger g_L U_e = g \mathbf{1} \\ &\Downarrow \\ &\boxed{g_L = g U_{PMNS}} \end{aligned}$$

exactly the same reasoning can be applied to quarks to obtain the CKM matrix

OUR QUESTION 2

What happens with neutrino
oscillations?

A (very) simplified picture of neutrino oscillations

$$\mathcal{A} = \mathcal{A}_L \frac{1}{s - m_\nu^2} \mathcal{A}_R + \mathcal{A}_{contact}$$

dominated by almost on-shell neutrinos! *

$$\mathcal{A} = \mathcal{A}_L \frac{1}{s - m_\nu^2} \mathcal{A}_R = \mathcal{A}_{SM} + \mathcal{A}_{int} + \mathcal{A}_{NP}$$

**complicated kinematic structures,
but an exact result at all orders in the EFT**

$$\mathcal{A}_{SM} = \frac{g^2}{m_W^2} U^T \frac{1}{s - m_\nu^2} U^* \times (\text{kinematic structure})$$

* Provided the W is off-shell and the amplitude is part of a larger amplitude
(not considered for simplicity)

Possible extensions

On the neutrino side

- Extend the deduction to $\mathcal{A}(qq\ell\ell)$ (alternative all-order formulation of non-standard interactions)
- Extend the deduction at $\mathcal{A}(\pi\ell\nu)$: how do we match to quarks?
- Neutrino oscillations in matter: how to treat them in this formalism?

More in general

- Phenomenological analysis of the all-order amplitudes with the SM particle content (on-shell generalization of the SMEFT fit...at all orders!)
- More conceptual/technical: how to take the high energy limit of an amplitude that in QFT is generated by the Higgs vev? Soft limit?
- ...

Backup

Massless particles

- 3-points amplitudes COMPLETELY FIXED by helicity:

$$\mathcal{A}(h_1, h_2, h_3) = g \langle 12 \rangle^{h_3 - h_1 - h_2} \langle 13 \rangle^{h_2 - h_1 - h_3} \langle 23 \rangle^{h_1 - h_2 - h_3}$$

$$\sum_i h_i < 0$$

$$\mathcal{A}(h_1, h_2, h_3) = g [12]^{h_1 + h_2 - h_3} [13]^{h_1 + h_3 - h_2} [23]^{h_2 + h_3 - h_1}$$

$$\sum_i h_i > 0$$

The Higgs mechanism bottom-up

Example: $\mathcal{A}(\psi\psi^c Z) \sim (g_L - g_R) \frac{m_\psi}{m_Z} \langle 12 \rangle$ well behaved as $m_\psi \rightarrow 0$ only if

- $g_L = g_R$ (vector-like fermion)
- $m_\psi \rightarrow 0$ as $m_Z \rightarrow 0$ (chiral fermion mass has the same origin as the vector mass)
