FASE ν

Conclusions

- The 2015 reference design for LBNF/DUNE was a NuMI-like movable target (segmented rectangular graphite fins with water cooling \approx 1m long) and 2 modified NuMI horns 6.6m apart
- In Sep 2017 LBNF adopted a focusing design with 3 horns optimized using a *genetic algorithm* with the physics parameter to be measured (CPV sensitivity) used to gauge fitness.
- Target geometry is optimized at the same time, as well as proton beam energy with realistic Main Injector power profile (1.03 MW at 60 GeV to 1.2 MW at 120 GeV).
- Limits on horn current, diameter and length are imposed based on experience with T2K and NuMI horn manufacturing
- Limits on horn separation imposed based on size of target chase.

Conclusions

The main sources of flux modeling uncertainties are:

- **Hadron production uncertainties:** driven by uncertainties in the hadron interaction models used to estimate hadron distributions exiting the target (prior to focusing) as well as secondary and tertiary interactions of hadrons with beamline material. **Fully evaluated for LBNF/DUNE using the ppx package developed for MINER ν A.**
- **Focusing uncertainties:** Dominated by horn material, geometry and magnetic field modeling as well as target geometry and density. Alignment of the neutrino beamline elements can also have large impact on ν flux. Includes proton counting uncertainties. **These uncertainties are assessed by simulating individual effects in Geant 4 and combining.**
- **Other beamline uncertainties:** Primarily uncertainties on the distribution of passive material in the beamline: for e.g. impact of Nitrogen in the target chase, decay pipe window thickness...etc. **Experience with NuMI indicates these are subdominant**

Conclusions

From A. Blondel et. al. NIM A 451 (2000) 102-122

	Conventional	Neutrino factory
Parents	π^+, K^+ or π^-, K^-	μ^- or μ^+
ν_μ beam	ν_μ	$\nu_\mu : \bar{\nu}_e = 1:1$
Background	$\sim 2\%$ of $\bar{\nu}_\mu$, $\sim 1\%$ of ν_e	none
$\bar{\nu}_\mu$ beam	$\bar{\nu}_\mu$	$\bar{\nu}_\mu : \nu_e = 1:1$
Background	$\sim 6\%$ of ν_μ , $\sim 0.5\%$ of $\bar{\nu}_e$	none
$\Delta E/E$ of neutrino energy	$\pm 10\%$	$< 1\%$
$\Delta R/R$ of neutrino radius	$\pm 10\%$	$< 1\%$
Neutrino flux uncertainty	$\pm 10\%$	$< 1\%$
ν_μ/cm^2 per year at 732 km	3×10^7 for 4.5×10^{19} 400 GeV/c p.o.t.	3×10^9 for 10^{21} injected 50 GeV/c μ

Neutrino factories technologically challenging - but best chance for probing $\nu_e \rightarrow \nu_\mu$ appearance Muon storage rings currently only viable for short baseline.

Conclusions

ν Exercise: At the SNS a pi^+ will decay at rest to a mu^+ and a ν_μ . This is a two body decay which leads to a monochromatic beam of ν_μ . What is the energy of the ν_μ ? Derive the two body formula for mass M decaying to $m_1 + m_2$ in the rest frame of M :

$$E_2 = \frac{M^2 + m_2^2 - m_1^2}{2M} \quad (1)$$

Conclusions

Neutrinos from colliding beams

Prompt neutrinos

- In pp collision at the LHC, various hadrons are produced.
- A number of neutrinos are produced from subsequent decay of the secondary hadrons.

$$\text{e.g.) } \pi, K, D, B \dots \rightarrow \nu + X$$

- Neutrinos generated from the decay of charmed/bottom hadrons are called prompt neutrinos.

Possible sites for detection

Ref:1903.06564 (CMS note)
1901.04468 (FASER)

- Near CMS interaction point (IP)
 - 25 m from IP (quadruplet region)
 - 90 & 120 m from IP (UJ53 & UJ57)
 - 240 m from IP (PR53 and PR57)
- Near ATLAS IP
 - 480 m from IP (TI18 and **TI12**)

Forward Neutrinos from the LHC

Making Neutrino Beams - I

Mary Bishai
Brookhaven National Laboratory

The ForwARD Search ExpeRiment (FASER ν) is an emulsion detector added to FASER an approved experiment dedicated to searching for light, extremely weakly interacting particles at the LHC located 480 m from the ATLAS interaction point. Calculations of forward neutrino fluxes at the LHC from [arXiv 2105.08270](https://arxiv.org/abs/2105.08270):

Conclusions

- **High energy and high power proton accelerators can be used to generate neutrino beams of all 3 flavors ν_e, ν_μ, ν_τ with energies from 10's of MeV to multi-TeV**
- **High purity ν_μ GeV-scale neutrino beams from pion decay-in-flight are used by short and long-baseline experiments to study $\nu_\mu \rightarrow \nu_e$ oscillations**
- **Neutrino beams from pion decay-at-rest with energies of 10's MeV are used for measurements of coherent neutrino-nucleus scattering as well as searches for non-standard oscillations**
- **Neutrino beams from muon decay-at-rest produce equal numbers of ν_μ and ν_e and can be used to study $\nu_e \rightarrow \nu_\mu$ oscillations**
- **Far forward experiments at the LHC can study multi-TeV neutrino interactions and produce ν_τ beams**
