

CARBON NANOMATERIALS APPLICATION FOR ISOL-METHOD OF HEAVY ION FUSION REACTION PRODUCTS

Saturday, 25 September 2021 14:50 (25 minutes)

The experiment directed to the study of a new carbon nanomaterials application was performed on the U-400M heavy ion beam at MASHA facility, FLNR, JINR. In the present speech a new technical improvements will be discussed such as usage of thin carbon nanotubes paper (thickness 6.4 mg/cm²) and graphene (thickness 1.1 mg/cm²) in the hot solid catcher block unit. The main goal of the experiment was to determine radiation resistance of these materials for ISOL method. Previous experimental researches performed with polygraphene structure, which represents a thermally expanded graphite hot catcher, showed an incompatibility with high intensity beams [1]. Measurements via new carbon nanomaterials showed also decreasing of the separation time for mercury in reaction $^{144}\text{Sm}(^{40}\text{Ar}, \text{xn})^{184}\text{-xHg}$. Thus, it became possible to gain statistics and to analyze 6n-evaporation channel decays (^{178}Hg) with the $T_{1/2}=0.266$ s at the focal plane of data acquisition system. Early separation time measurements performed by beam interruption method [2] showed average separation time for mercury 1.8 ± 0.3 s. The improvements of ISOL method application allow synthesizing new products at the beam intensities up to 0.5 pA and even more for the Super Heavy Element factory perspective in FLNR, JINR. Consequently, the experiment with carbon nanotubes paper demonstrated perspectives for the fusion reaction products separation at MASHA facility due to its radiation resistance and shorter response time.
