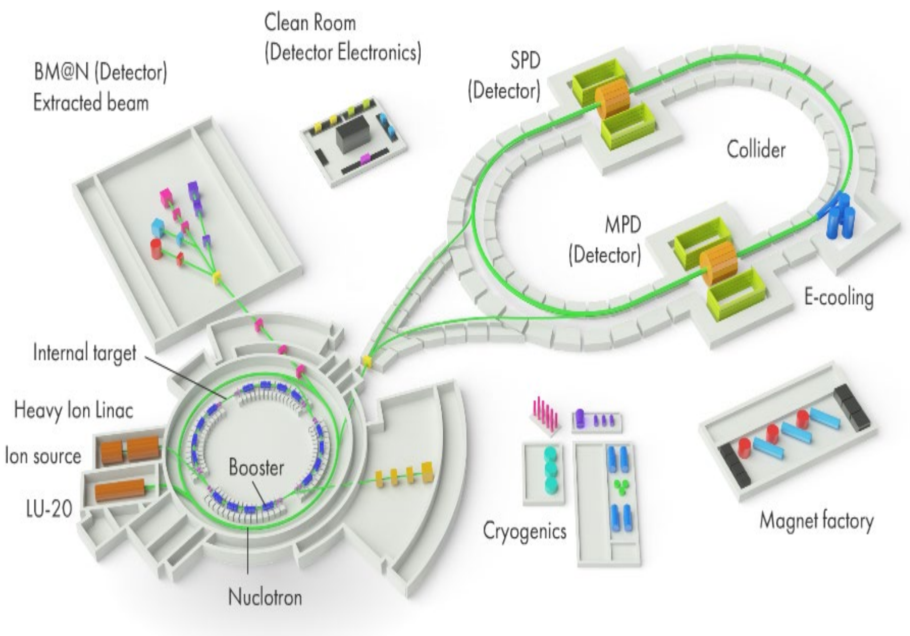
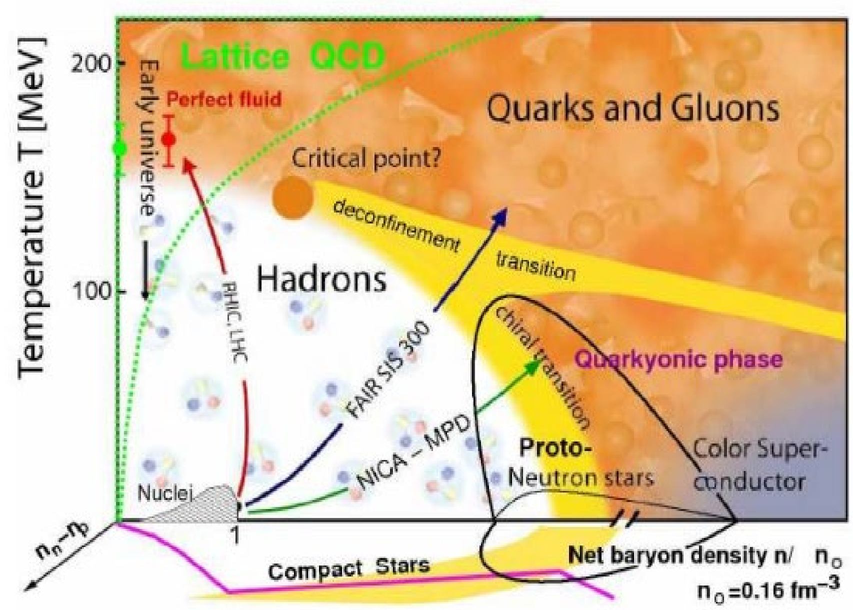
This work was supported by RFBR according to the research project № 18-02-40038

Heavy ion collisions at NICA





- A mega-science project NICA, Dubna, JINR
- Modernization of existing Nuclotron facility
- Parameters:
  - ✓ relativistic ions up to Au, $\sqrt{s_{NN}} = 4\text{-}11$ GeV
  - ✓ polarized p and d, $\sqrt{s_{NN}} = 27$ GeV (for p)
  - ✓ luminosity 10^{27} cm^{-2}s^{-1}
- Working experiment: BM@N (fixed target)
- Experiments under construction: MPD, SPD (collider)

- Study of the phase diagram in the region of high baryonic density and intermediate temperatures
- Extension of modern heavy-ion programs at RHIC and the LHC to lower energies

Resonances in heavy-ion collisions

- Wide variety of resonances in the PDG, most often/easily measured are:

$\rho(770)$	$K^*(892)^0$	$K^*(892)^+$	$\phi(1020)$	$\Sigma(1385)^\pm$	$\Lambda(1520)$	$\Xi(1530)$
$\frac{u\bar{u}+d\bar{d}}{\sqrt{2}}$	$d\bar{s}$	$u\bar{s}$	$s\bar{s}$	uus dds	uds	uss

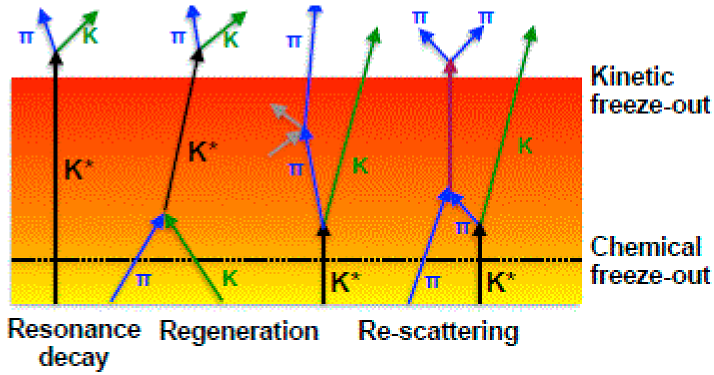
Particle	Mass (MeV/c^2)	Width (MeV/c^2)	Decay	BR (%)
ρ^0	770	150	$\pi^+\pi^-$	100
$K^{*\pm}$	892	50.3	$\pi^\pm K_s$	33.3
K^{*0}	896	47.3	π^-K^+	66.7
ϕ	1019	4.27	K^+K^-	48.9
Σ^{*+}	1383	36	$\pi^+\Lambda$	87
Σ^{*-}	1387	39.4	$\pi^-\Lambda$	87
$\Lambda(1520)$	1520	15.7	K^-p	22.5
Ξ^{*0}	1532	9.1	$\pi^+\Xi^-$	66.7

- Vacuum properties of the resonances are well defined (m, cτ, BR etc.)
- Copiously produced in heavy-ion collisions at ~ GeV energies, large branching ratios in hadronic decay channels → possible to measure
- Probe reaction dynamics and particle production mechanisms vs. system size and $\sqrt{s_{NN}}$:
  - ✓ hadron chemistry and strangeness production, ϕ with hidden strangeness is one of the key probes
  - ✓ reaction dynamics and shape of particle p_T spectra, p/K*, p/ϕ vs. p_T
  - ✓ lifetime and properties of the hadronic phase
  - ✓ spin alignment of vector mesons in rotating QGP (polarization of quarks from spin-orbital interactions)
  - ✓ flow, comparison with e^+e^- measurements, jet quenching, background for other probes etc.

Resonance yields at RHIC and LHC energies

increasing lifetime ⟶

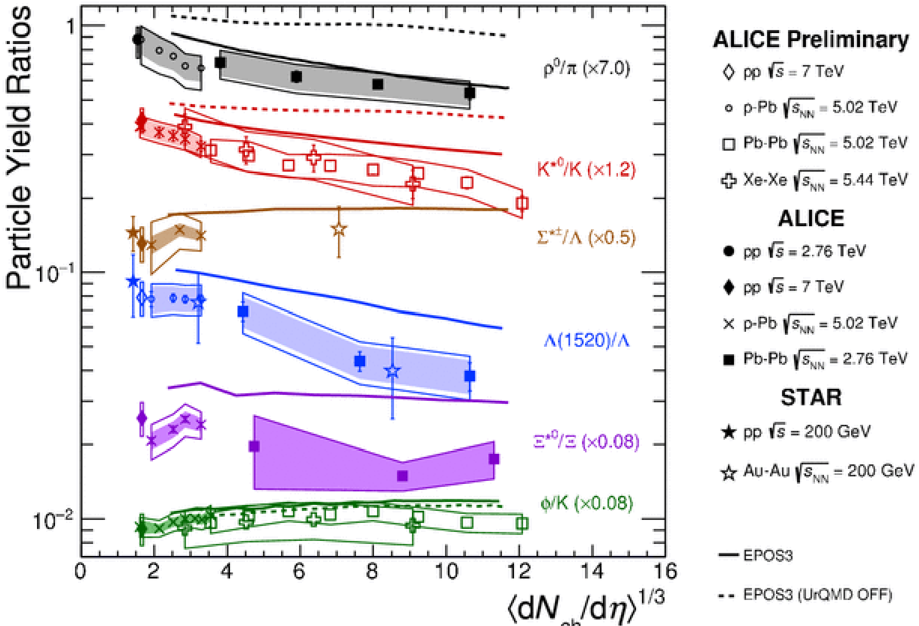
	ρ(770)	K^*(892)	Σ(1385)	Λ(1520)	Ξ(1530)	ϕ(1020)
cτ (fm/c)	1.3	4.2	5.5	12.7	21.7	46.2
$\sigma_{rescatt}$	$\sigma_\pi\sigma_\pi$	$\sigma_\pi\sigma_K$	$\sigma_\pi\sigma_\Lambda$	$\sigma_K\sigma_p$	$\sigma_\pi\sigma_\Xi$	$\sigma_K\sigma_K$



- Resonances have small lifetimes of cτ ~ 1 – 45 fm/c, part of them decays in the fireball
- Reconstructed resonance yields in heavy ion collisions are defined by:
  - resonance yields at chemical freeze-out
  - hadronic processes between chemical and kinetic freeze-outs:

    rescattering: daughter particles undergo elastic scattering or pseudo-elastic scattering through a different resonance → parent particle is not reconstructed → loss of signal

    regeneration: pseudo-elastic scattering of decay products (πK → K^{*0}, KK→ ϕ etc.) → increased yields



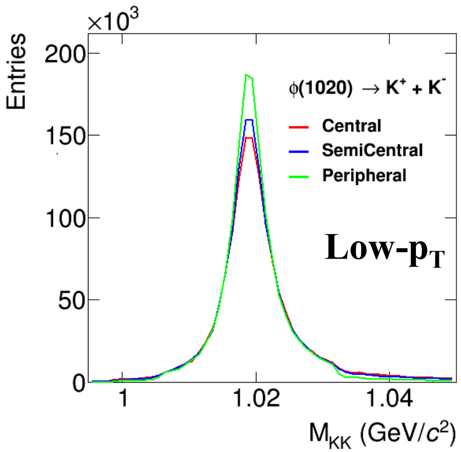
- ❖ SPS/RHIC/LHC observed multiplicity dependent suppression of ρ/π, K*/K, Λ*/Λ ratios, resonances with cτ ≤ 20 fm/c. Ratios of longer lived resonances are not affected
- ❖ Results support the existence of a hadronic phase that lives long enough to cause a significant reduction of the reconstructed yields of short lived resonances
- ❖ Hadronic phase lifetime, τ ~ 10 fm/c*
- ❖ NICA: $\langle dN_{ch}/d\eta\rangle^{1/3}$ ~ 6** → RHIC/LHC report modifications at such multiplicities

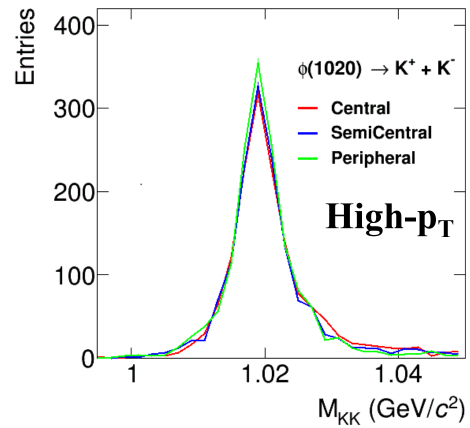
* ALICE, Phys.Lett.B 802 (2020) 135225, Phys.Rev.C 99 (2019) 024905

** PHENIX, Phys.Rev.C 93 (2016) 2, 024901

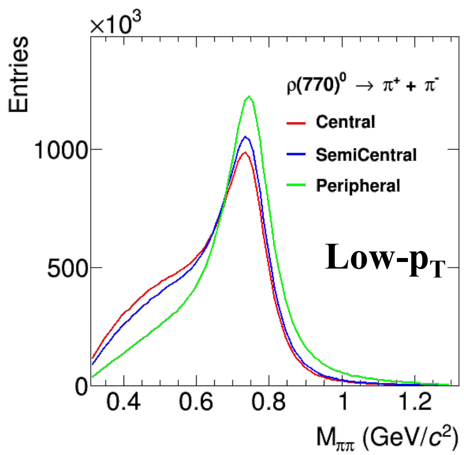
Resonances in AuAu@11, UrQMD

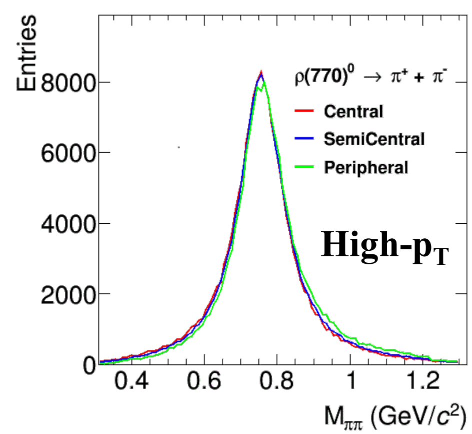
- Resonances are decayed by UrQMD, daughters participate in elastic and inelastic scattering
- Resonance are reconstructed by invariant mass method according to decay channels
- $\phi \rightarrow K^+K^-$ ($c\tau \sim 45$ fm/c): modest line shape, modifications in central AuAu@11 at low p_T





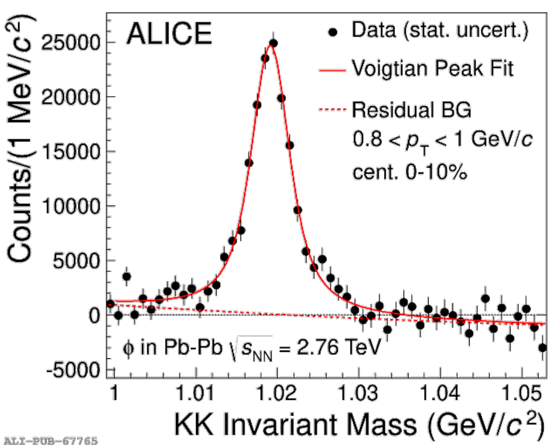
- $\rho(770)^0 \rightarrow \pi^+\pi^-$ ($c\tau \sim 1.3$ fm/c): significant line shape, modifications in central AuAu@11 at low p_T

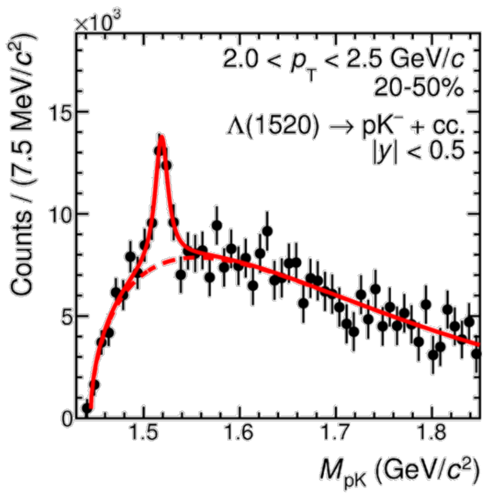


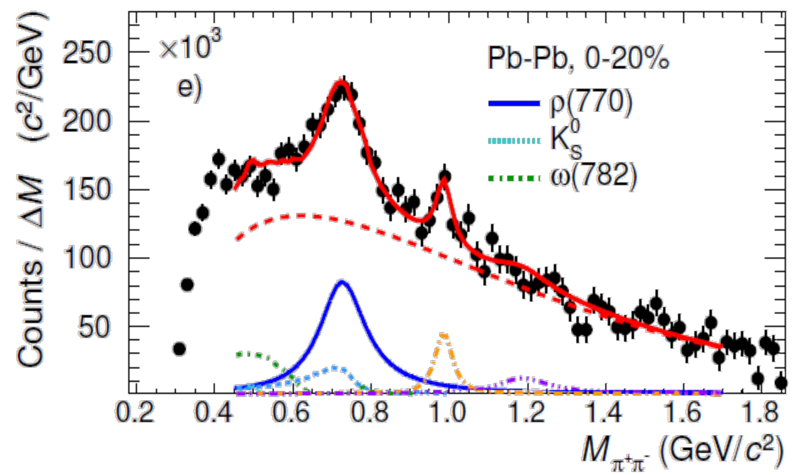


Resonance reconstruction

- Hadronic decays of resonances are studied with the invariant mass method in the experiments
- After subtraction of uncorrelated combinatorial background estimated with mixed-event pairs, like-sigh pairs, rotation pairs etc., the resonance peaks are approximated with a given peak-model (rBW + mass resolution + mass-dependent width + phase space correction + …) + background function
- Examples of invariant mass distributions and fits from ALICE for ϕ, $\Lambda(1520)$ and $\rho(770)^0$:



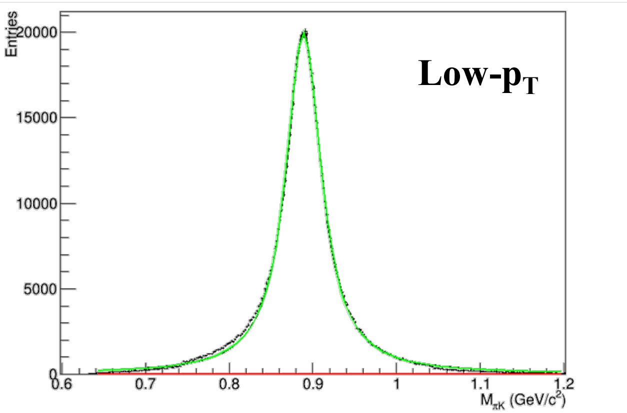


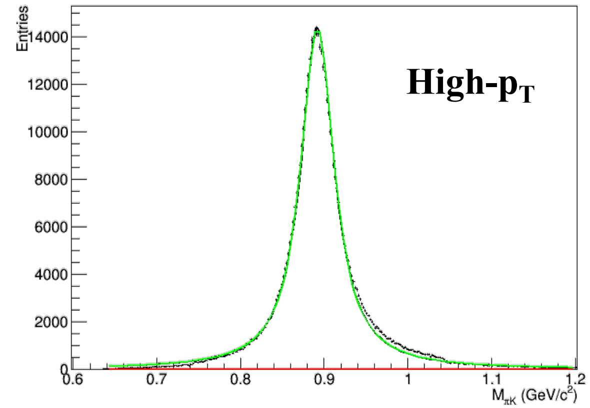


- For most of the cases, the peak models are inspired by theory and measurement in elementary e^+e^- and/or pp collisions where medium effects are not as important
- Line shape modifications will result in the change of the measured yield and masses/widths

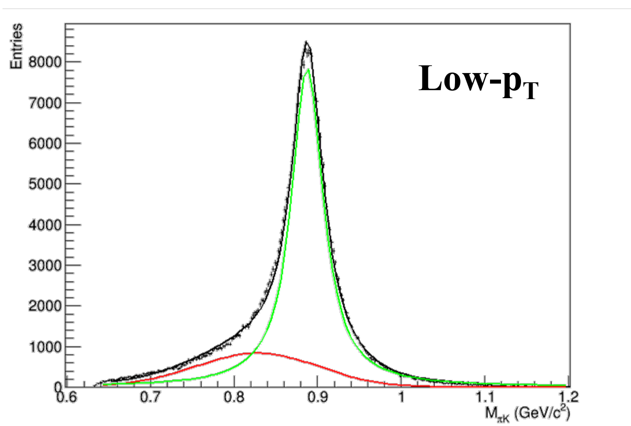
Yield and mass modifications in AuAu@11, UrQMD

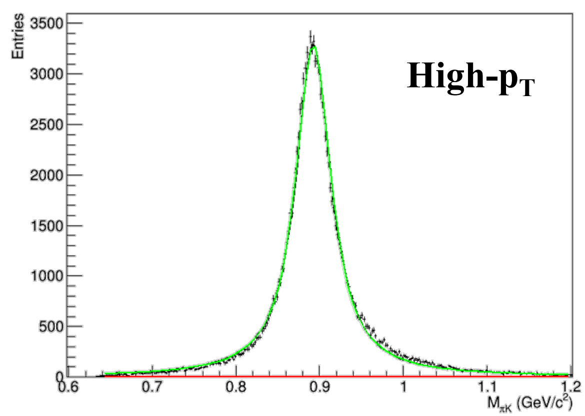
- $K^*(892)^0 \to \pi^\pm K^\pm$ ($c\tau \sim 4.2$ fm/c); combine $\pi^\pm K^\pm$ pairs from true $K^*(892)^0$ decays
- Same fitting function for $K^*(892)^0$ and background as in ALICE
- Peripheral collisions: nothing





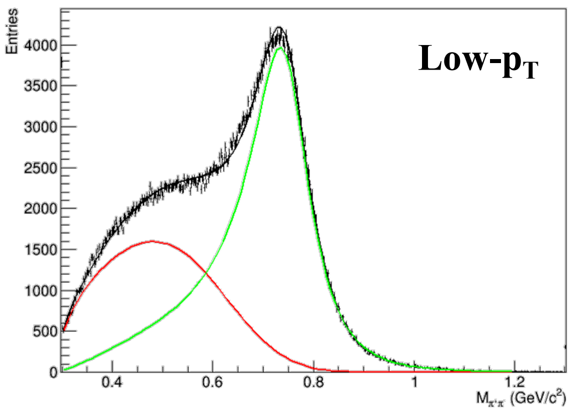
- Central collisions: small line shape modifications at low p_T; nothing at higher momentum

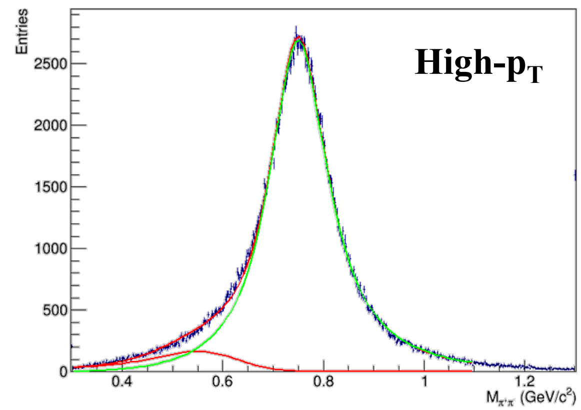




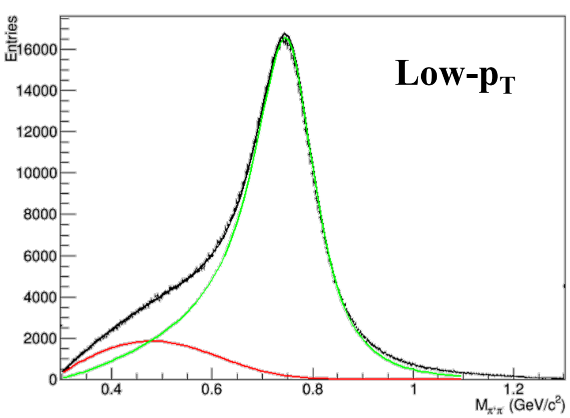
Yield and mass modifications in AuAu@11, UrQMD

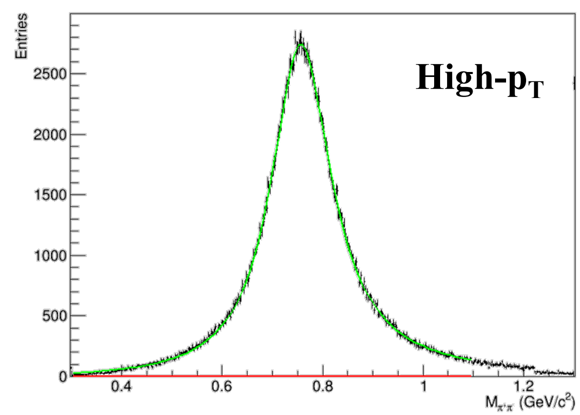
- $\rho(770)^0 \rightarrow \pi^+\pi^-$ ($c\tau \sim 1.3$ fm/c); combine $\pi^+\pi^-$ pairs from true $\rho(770)^0$ decays
- Same fitting function for $\rho(770)^0$ and background as in ALICE
- Central collisions: significant line shape modifications; excess with respect to the peak model is described with a background function





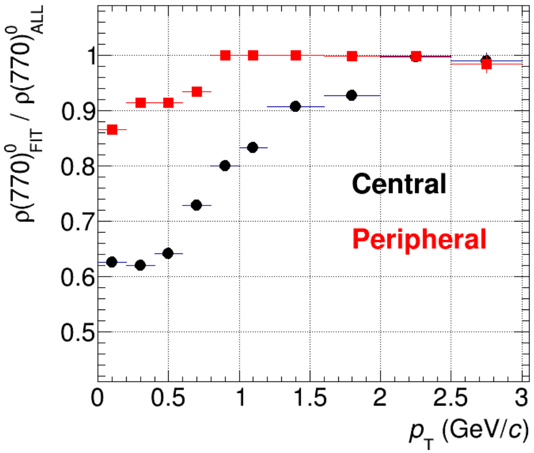
- Peripheral collisions: much smaller modifications are observed, only at low momentum



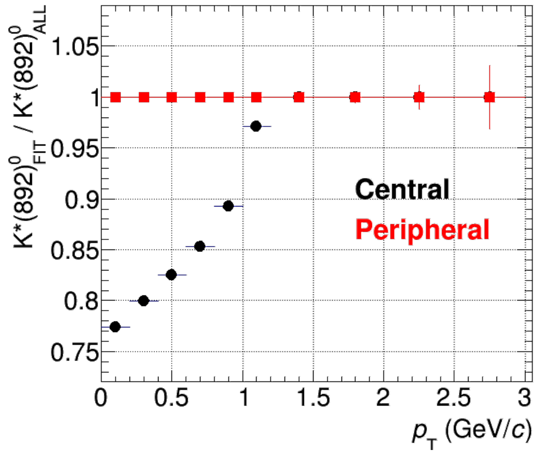


Yields of $K^*(892)^0$ and $\rho(770)^0$ in AuAu@11, UrQMD

- ❖ $\rho(770)^0 \rightarrow \pi^+\pi^-$ ($c\tau \sim 1.3$ fm/c)
  - ✓ yield is undercounted because of pion rescattering;



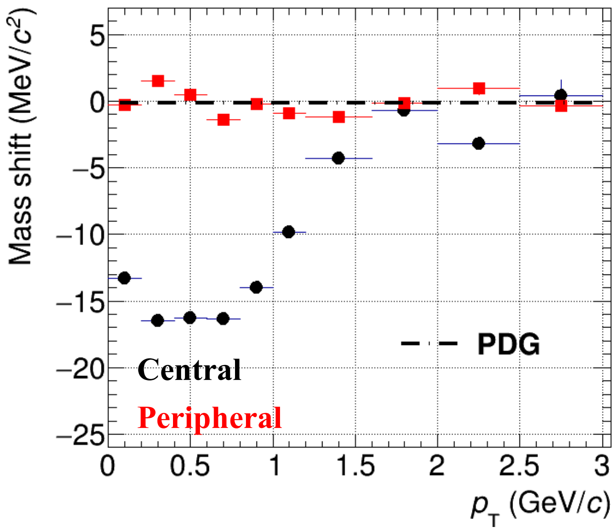
- ❖ $K^*(892)^0 \rightarrow \pi^\pm K^\pm$ ($c\tau \sim 4.3$ fm/c)
  - ✓ yield is undercounted because of pion and kaon rescattering



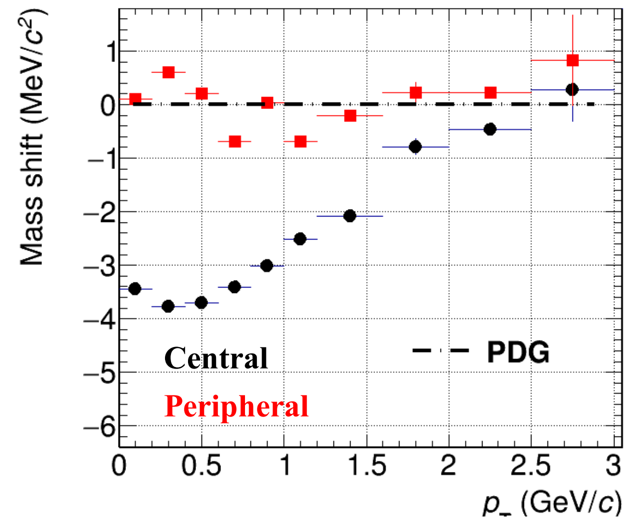
- ❖ Signal losses are larger for shorter-lived $\rho(770)^0$ → higher chance for $\rho(770)^0$ to decay and for daughters to rescatter in the medium
- ❖ Predicted signal losses are noticeable for the total (p_T-integrated) yields since bulk of the hadrons is produced at low p_T at NICA energies

Masses of $K^{*}(892)^{0}$ and $\rho(770)^{0}$ in AuAu@11, UrQMD

❖ $\rho(770)^0 \to \pi^+\pi^-$ ($c\tau \sim 1.3$ fm/c)



❖ $K^*(892)^0 \to \pi^\pm K^\pm$ ($c\tau \sim 4.3$ fm/c)

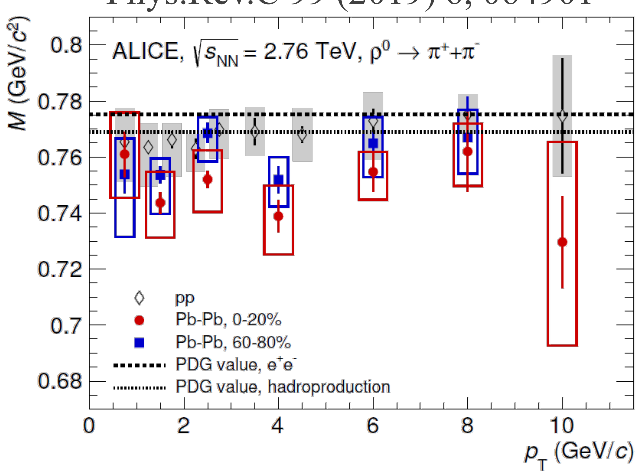


❖ In peripheral collisions, the peak models return masses and widths as measured in vacuum

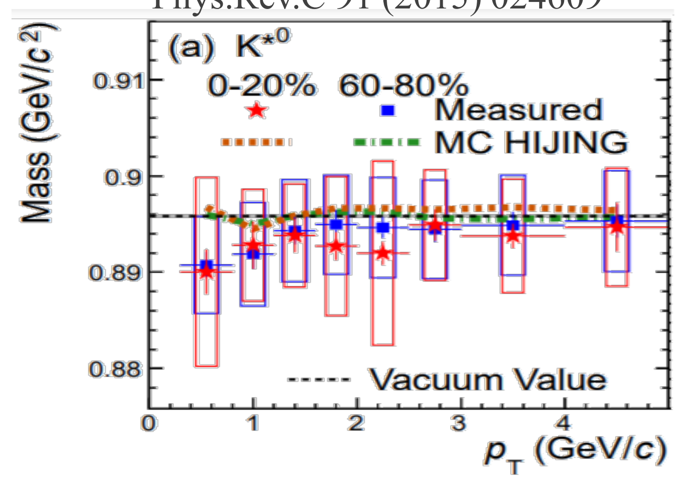
❖ In central collisions, the masses are measured smaller

❖ Similar mass “modifications” have been reported @ RHIC and the LHC, large uncertainties:

Phys.Rev.C 99 (2019) 6, 064901

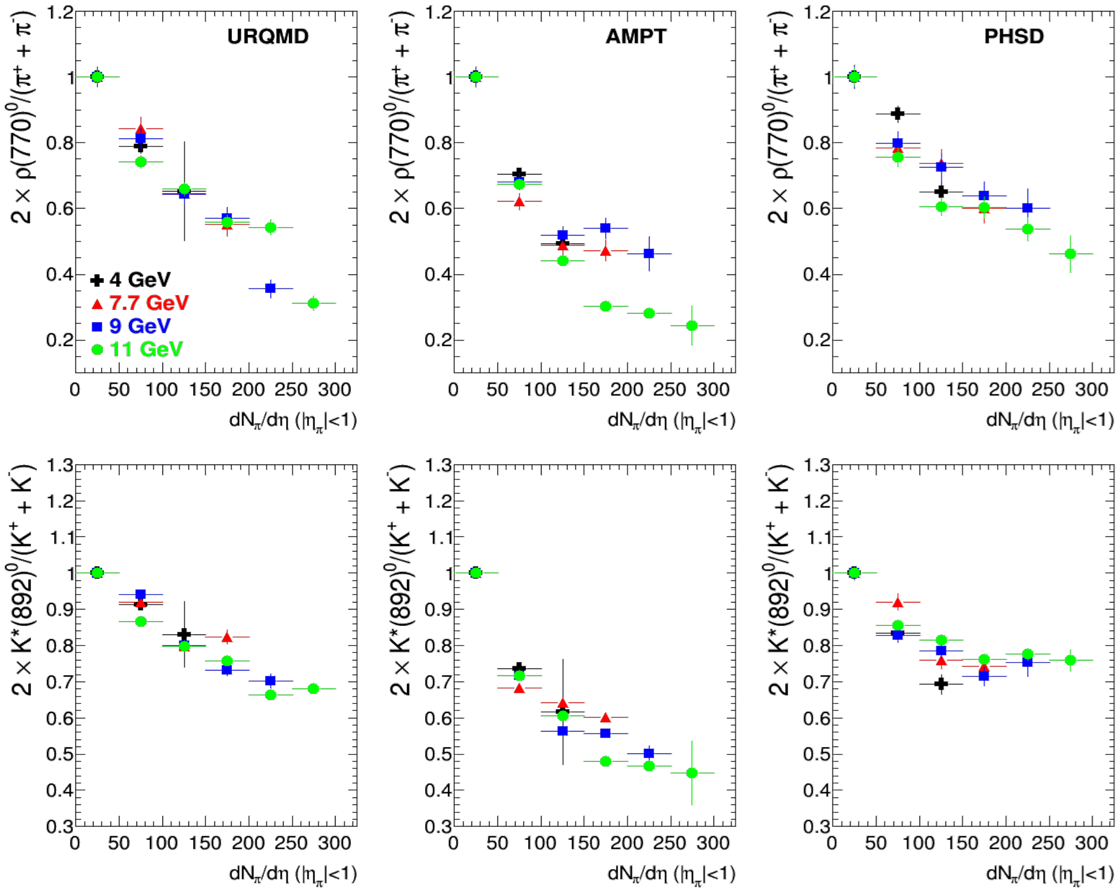


Phys.Rev.C 91 (2015) 024609



Particle ratios in AuAu@4-11, UrQMD, AMPT, PHSD

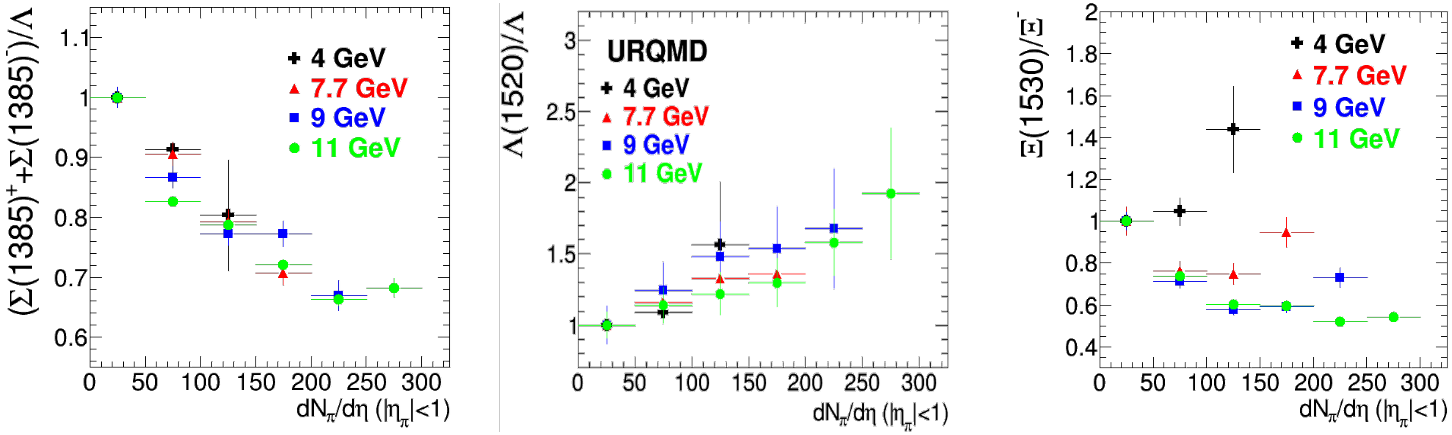
- ❖ Models with hadronic cascades (UrQMD, PHSD, AMPT)
- ❖ Ratios for two shortest-lived resonances (ϕ, $K^*(892)$) are shown normalized to most peripheral collisions

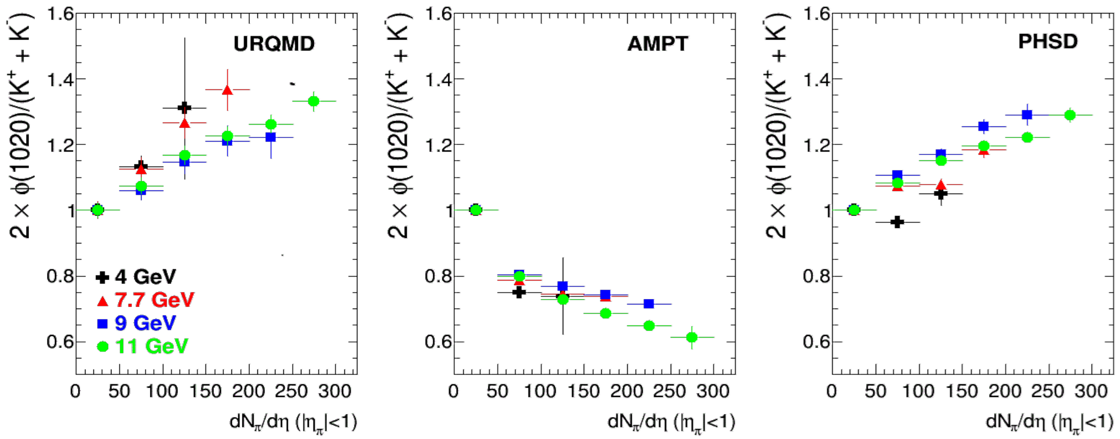


- ➢ Models predict suppression of ρ/π and K^*/K ratios in Au+Au@4-11, resonances with small $c\tau$
- ➢ Suppression depends on the final state multiplicity rather than on collision energy
- ➢ Yield losses occur at low momentum as has been demonstrated before

Particle ratios in AuAu@4-11, UrQMD, AMPT, PHSD

- ❖ Models with hadronic cascades (UrQMD, PHSD, AMPT)
- ❖ Ratios for longer-lived resonances (Σ(1385), Λ(1520), Ξ(1530) and ϕ)

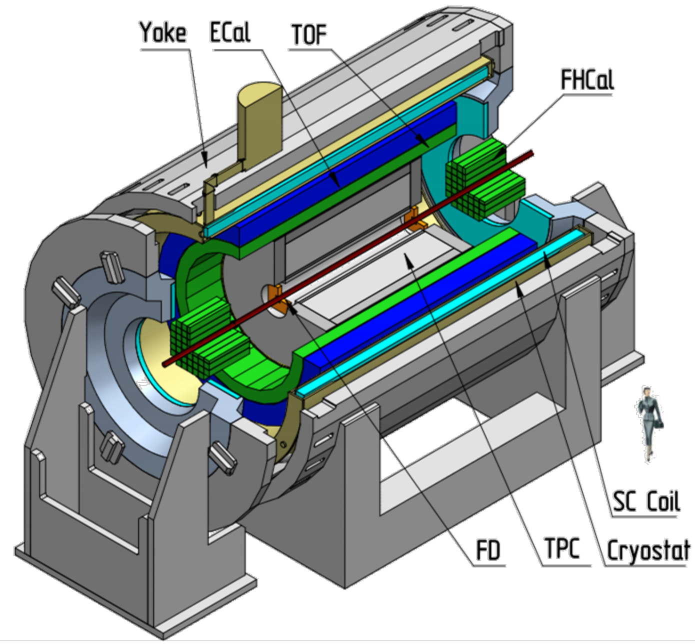




- ❖ Event generators predict yield modifications qualitatively similar to those obtained at RHIC/LHC:
  - → lifetime and density of the hadronic phase are high enough
  - → modification of particle properties in the hadronic phase should be taken into account when model predictions for different observables are compared to data
  - → study of short-lived resonances is a unique tool to tune simulations of the hadronic phase

MPD experiment, Stage-1

- Stage-1: **TPC, TOF, FFD, FHCAL и ECAL**
- Startup in 2023, BiBi@9.2



- Simulate BiBi@9.2 collisions with UrQMD
- Propagate particles through the MPD, 'mpdroot':
  - ✓ Geant (v.3 or v.4) for particle transport
  - ✓ realistic simulation of subsystem response (raw signals)
  - ✓ track/signal reconstruction and pattern recognition

- Basic event and track selections:
  - ✓ event selection: $|Z_{vrtx}| < 50$ cm
  - ✓ track selection:
    - number of TPC hits > 24
    - $|\eta| < 1.0$
    - |DCA to PV| < 3σ for primary tracks
    - V0 topology cuts for weakly decaying secondaries
    - $p_T > 100$ MeV/c
    - TPC-TOF combined π/K/p PID
  - ✓ combinatorial background:
    - event mixing ($|\Delta_{Zvrtx}| < 2$ cm, $|\Delta_{Mult}| < 20$, $N_{ev} = 10$)

TPC: $|\Delta\varphi| < 2\pi$, $|\eta| \leq 1.6$

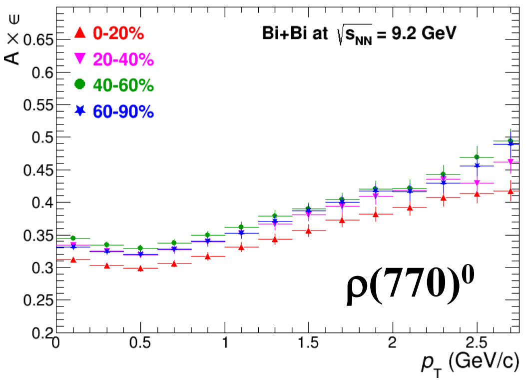
TOF, EMC: $|\Delta\varphi| < 2\pi$, $|\eta| \leq 1.4$

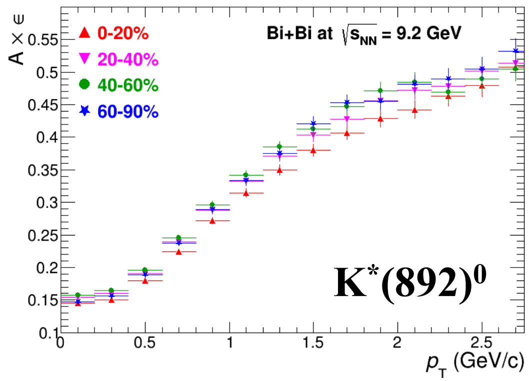
FFD: $|\Delta\varphi| < 2\pi$, $2.9 < |\eta| < 3.3$

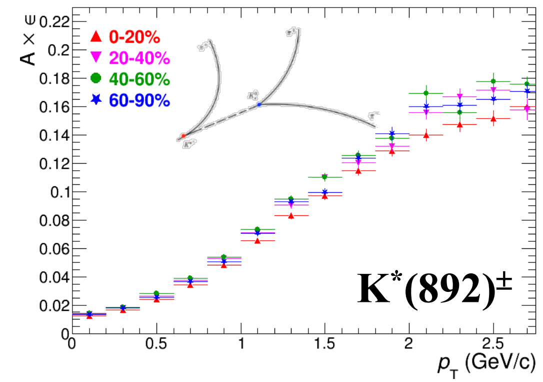
FHCAL: $|\Delta\varphi| < 2\pi$, $2 < |\eta| < 5$

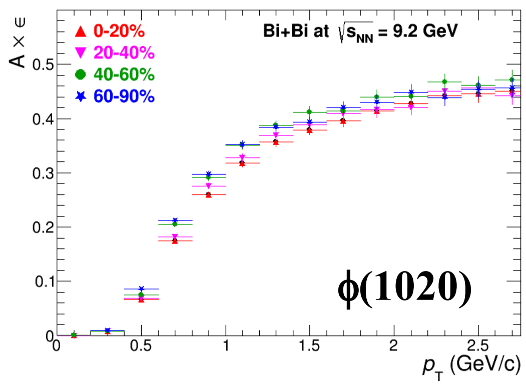
Reconstruction efficiencies, BiBi@9.2

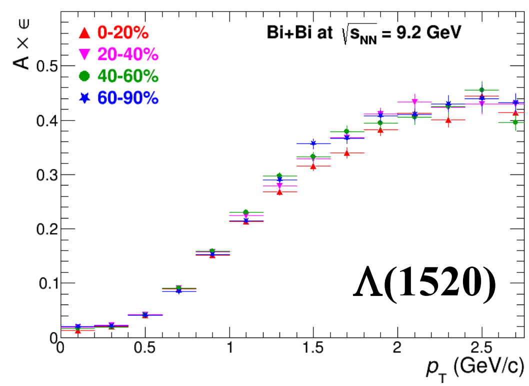
❖ Typical reconstruction efficiencies (A x ∊) at different centralities, |y| < 1

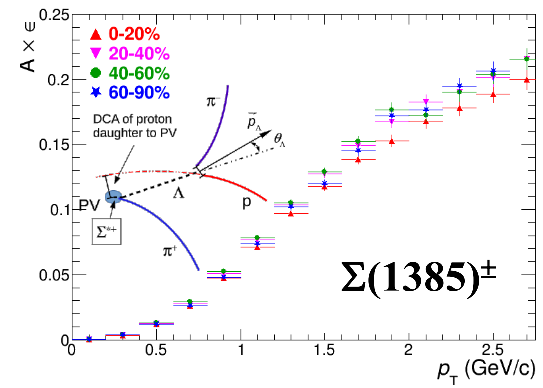


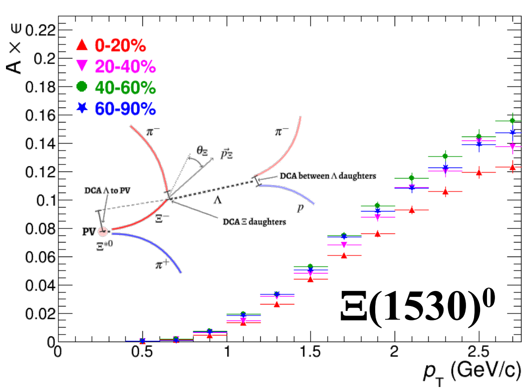












❖ Reasonable efficiencies in the wide p_T range, |y| < 1

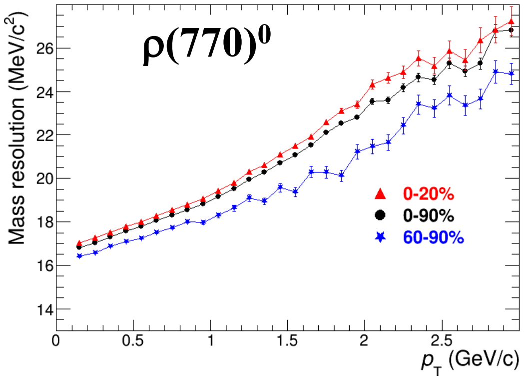
❖ Efficiencies are noticeably lower for multi-stage decays with weakly decaying daughters (Ξ, Λ, K_s^0)

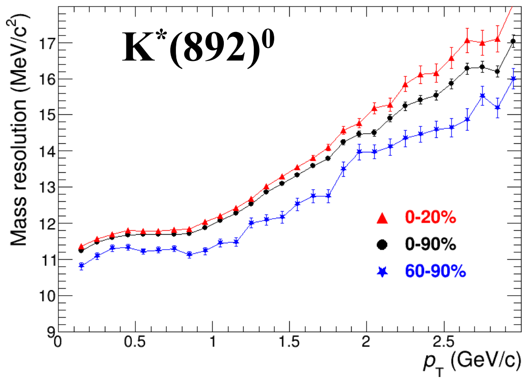
❖ Measurements are possible from zero momentum

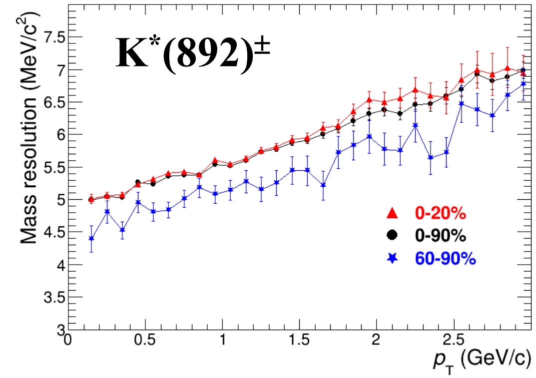
❖ Modest multiplicity dependence

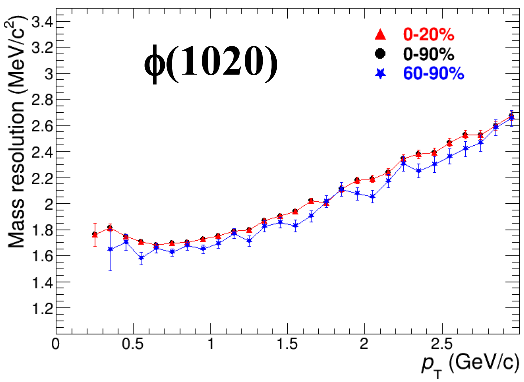
Mass resolution, BiBi@9.2

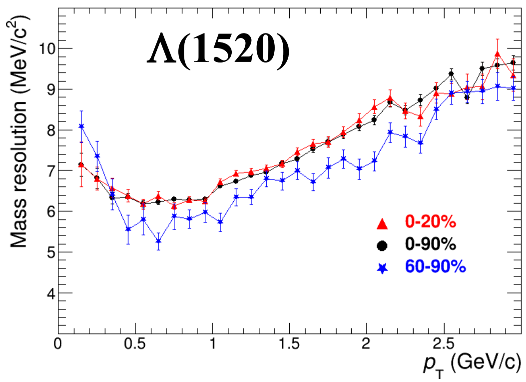
Detector mass resolution ($m_{reconstructed} - m_{generated}$) in central, minbias and peripheral BiBi, $|y| < 1$

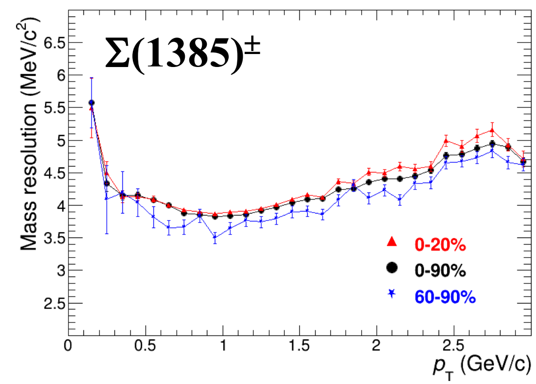


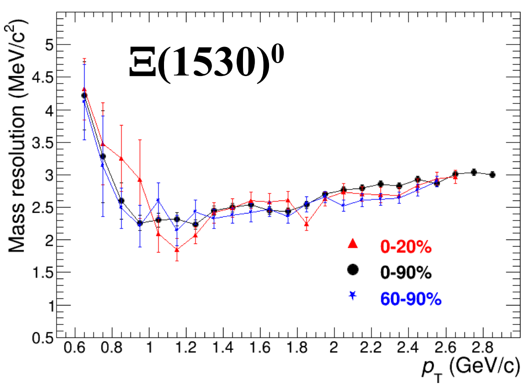










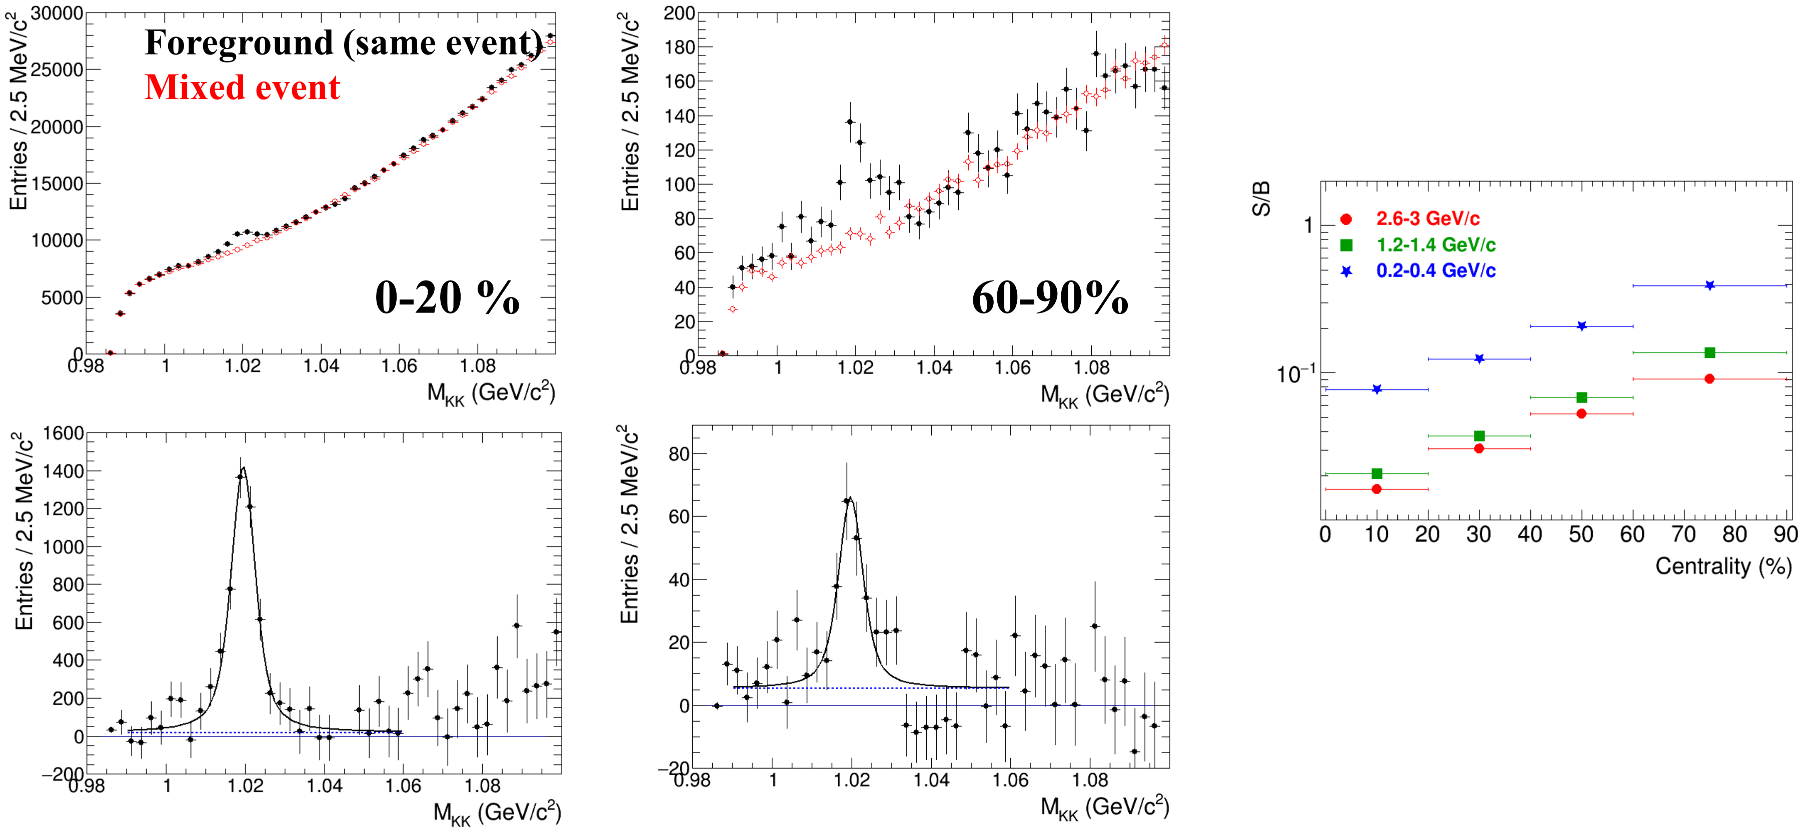


- Mass resolution is good enough to preserve the capability for the line shape analysis
- Modest multiplicity dependence

ϕ(1020), reconstructed peaks

❖ UrQMD v.3.4: BiBi@9.2 (5M events)

❖ Full chain simulation and reconstruction, p_T = 0.2-0.4 GeV/c, |y| < 1



❖ Mixed-event combinatorial background is scaled to foreground at high mass and subtracted

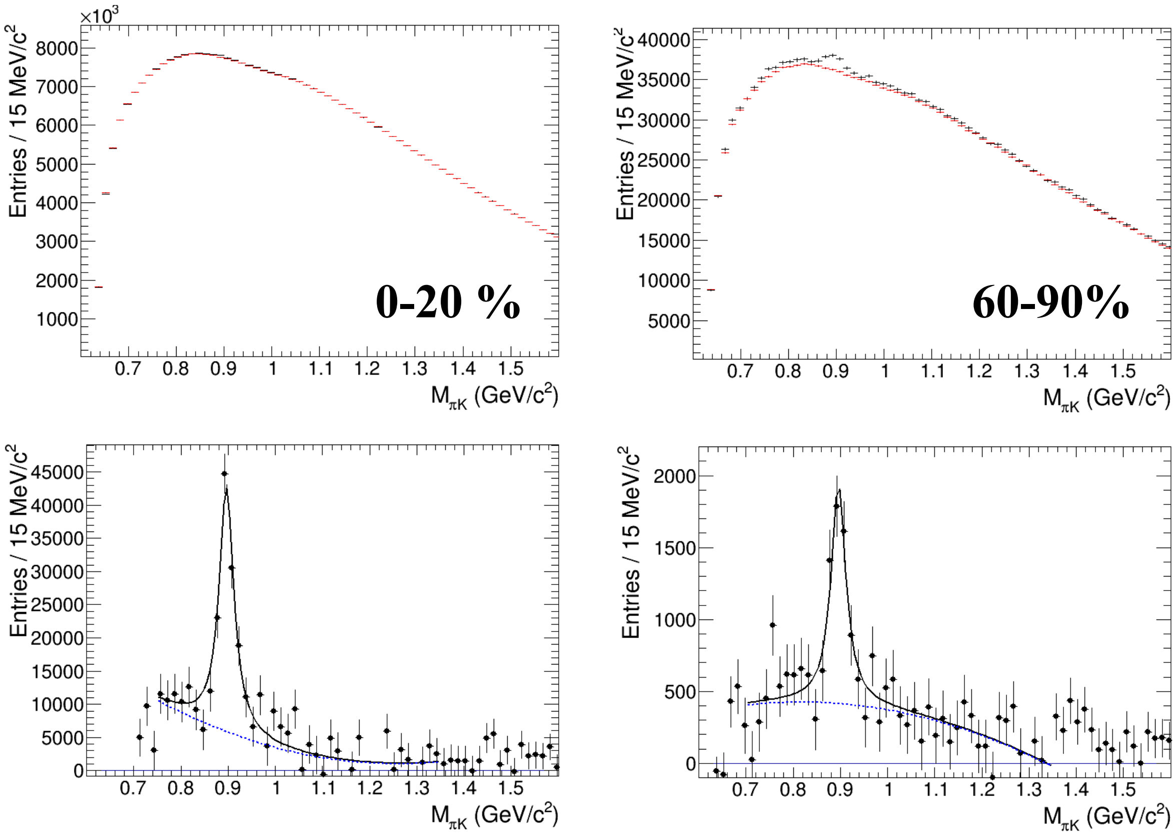
❖ Distributions are fit to Voigtian function + polynomial

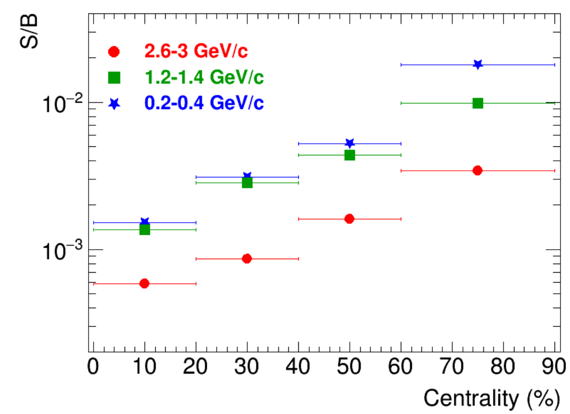
❖ Signal can be reconstructed at p_T > 0.2 GeV/c, high-p_T reach is limited by available statistics

❖ S/B ratios deteriorates in more central collisions at higher momenta

$K^*(892)^0$, reconstructed peaks

- UrQMD v.3.4: BiBi@9.2 (5M events)
- Full chain simulation and reconstruction, p_T = 1.2-1.4 GeV/c, |y| < 1



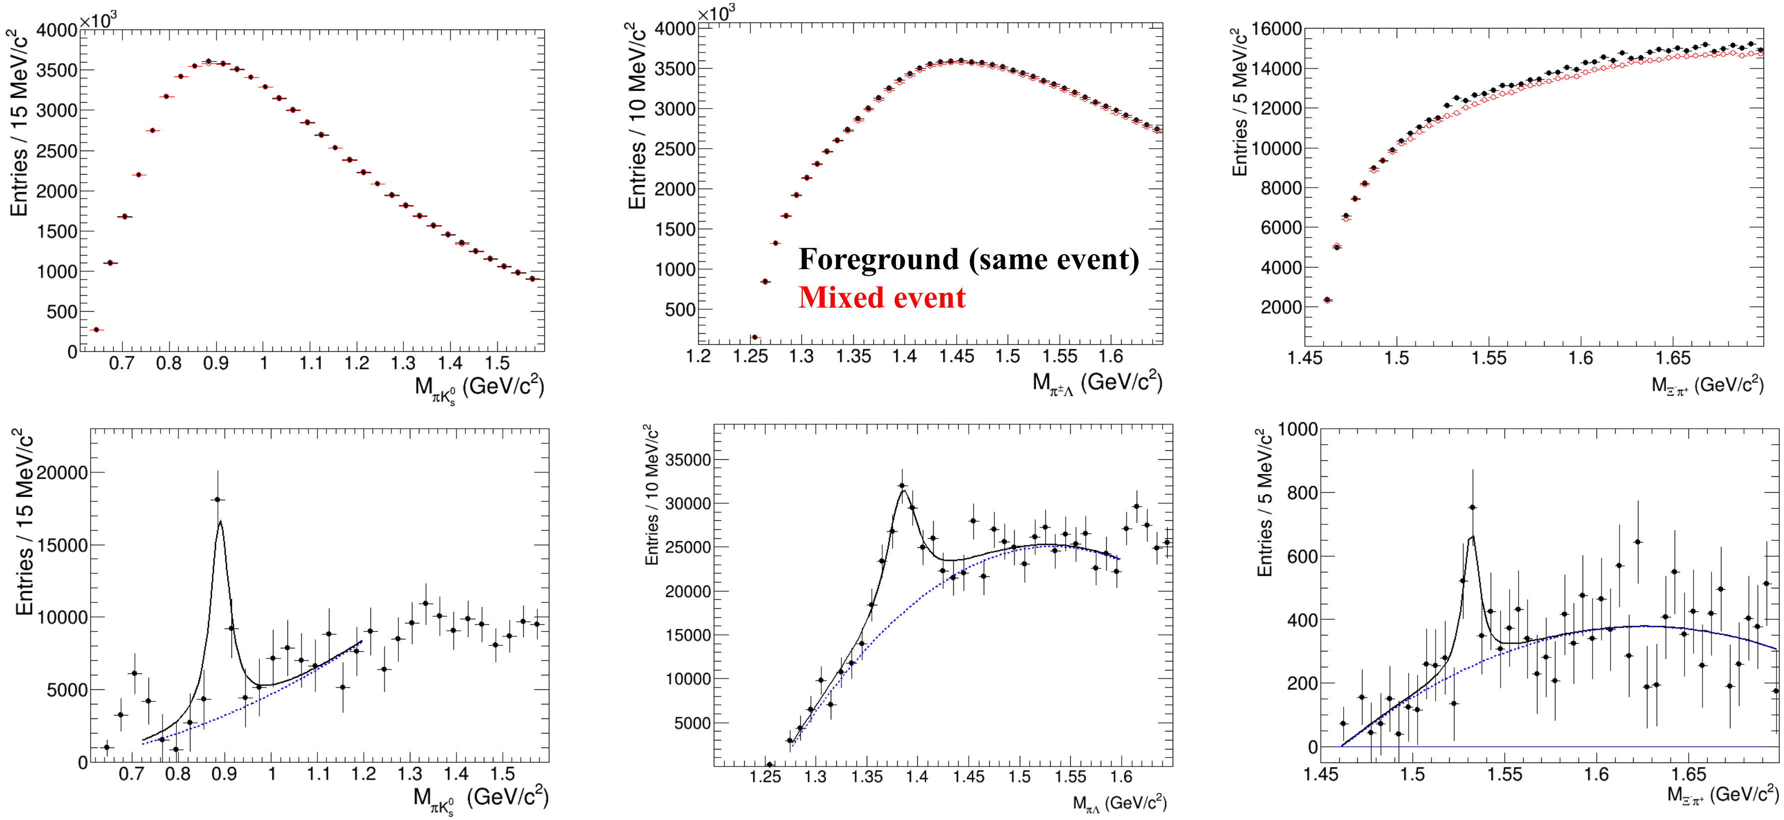


- Mixed-event combinatorial background is scaled to foreground at high mass and subtracted
- Distributions are fit to Voigtian function + polynomial
- Signal can be reconstructed at p_T > 0.2 GeV/c, high-p_T reach is limited by available statistics
- S/B ratios deteriorates in more central collisions at higher momenta

K*(892)$^{\pm}$, Σ(1385)$^{\pm}$, Ξ(1530)^0, reconstructed peaks

❖ UrQMD v.3.4: BiBi@9.2 (5M events), full chain simulation and reconstruction, |y| < 1

K$^{*\pm}$, 0.2-0.4 GeV/c **Σ(1385)$^{\pm}$, 0-0.5 GeV/c** **Ξ(1530)^0, 0.5-1 GeV/c**



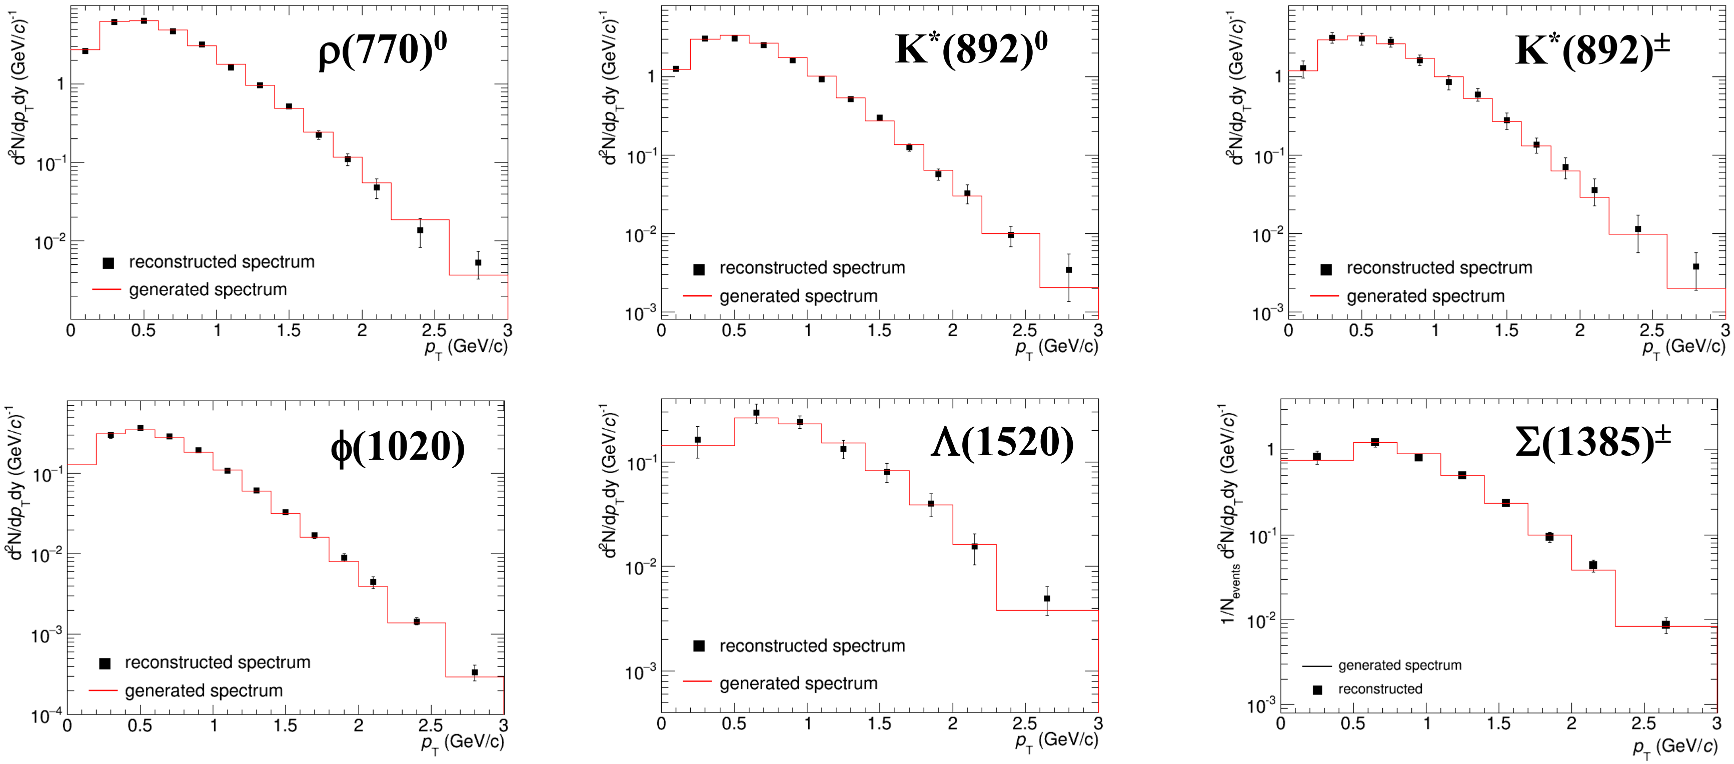
❖ Can reconstruct signals for multistage decays of K*(892)$^{\pm}$ → $K_S^0\pi^{\pm}$ ($K_S^0 \to \pi^+\pi^-$), Σ(1385)$^{\pm}$ → $\pi^{\pm}\Lambda$ ($\Lambda\to p\pi$) and Ξ(1530)^0→ $\pi^+\Xi^-$ ($\Xi^- \to \Lambda\pi^-$, ($\Lambda\to p\ \pi^-$))

❖ Distributions are fit to Voigtian function + polynomial

❖ Signal can be reconstructed starting from p_T > 0 GeV/c, high-p_T reach is limited by available statistics

Production spectra and MC closure test

- UrQMD v.3.4: BiBi@9.2 (5M events)
- Full chain simulation and reconstruction, p_T ranges are limited by the possibility to extract signals, $|y| < 1$



- Reconstructed spectra match the generated ones within uncertainties
- First measurements for resonances will be possible with accumulation of ~ 10^7 Bi+Bi@9.2 events
- Measurements are possible starting from ~ zero momentum → sample most of the yield, sensitive to possible modifications
- Measurements of $\Xi(1530)^0$ are very statistics hungry

Conclusions and outlook

- ❖ Measurement of resonances contribute to the MPD physical program
  - ✓ hadronic phase properties, strangeness production, hadronization mechanisms and collectivity, hadrochemistry, spin alignment etc …

✓ First measurements for resonances will be possible with ~10^7 sampled BiBi@9.2 → possibility for year-1 measurements

✓ Measurements are possible starting from very low momenta (for most of the cases from zero momenta) with decent mass resolution → high sensitivity to different physics phenomena most prominent at low p_T

✓ More detailed and multiplicity-dependent studies would require × 10 - 50 larger statistics, especially for multi-stage decays of $K^*(892)^{\pm}$, $\Sigma(1385)^{\pm}$ and $\Xi(1520)^0$

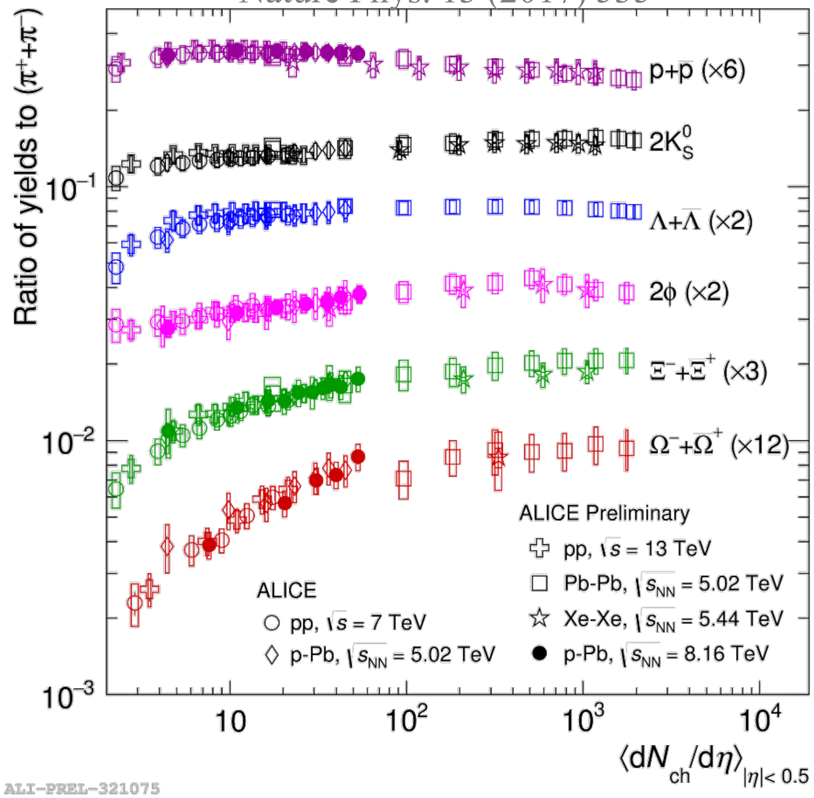
Strangeness production: pp, p-A and A-A

Nature Phys. 13 (2017) 535



|S| = 0

|S| = 1

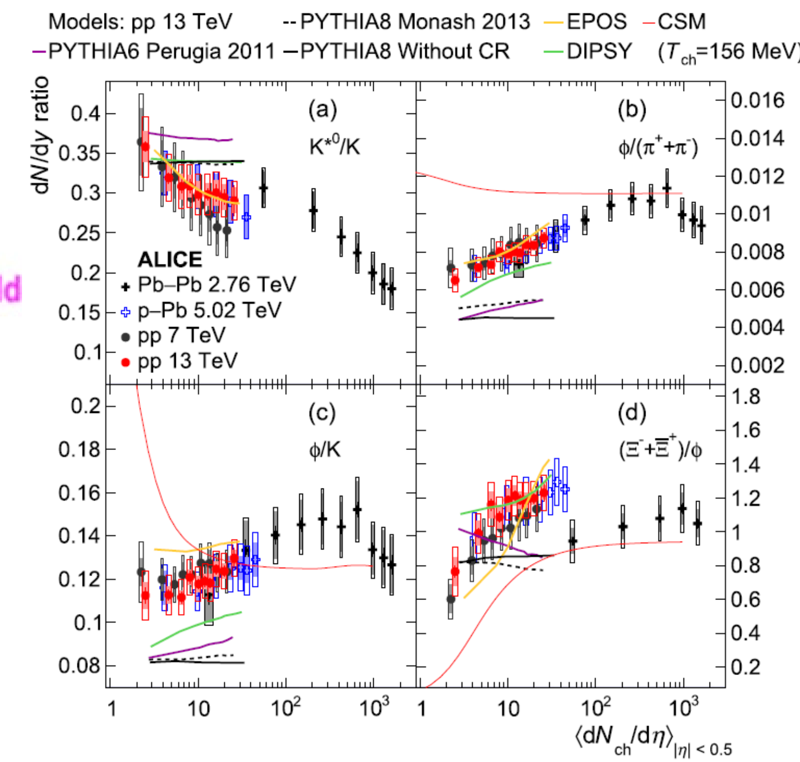
|S| = 1

|S| = 0 (hidd

|S| = 2

|S| = 3

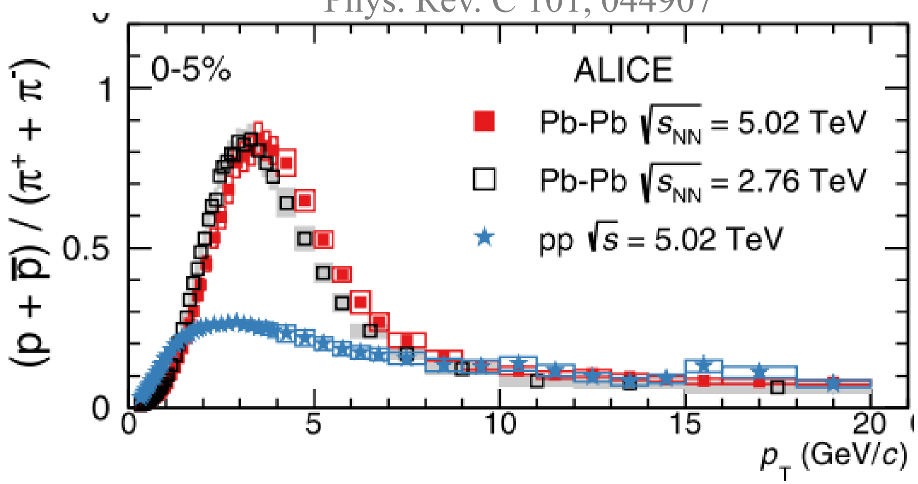
Phys. Lett. B807 135501(2020)



- Smooth evolution vs. multiplicity in pp, p-Pb, Xe-Xe, Pb-Pb collisions at $\sqrt{s_{NN}}$ = 0.2-13 TeV
- Strangeness enhancement increases with strangeness content and particle multiplicity
- Origin of the strangeness enhancement in small/large systems is still under debate
- ϕ with hidden strangeness is a key probe to study strangeness enhancement
  - ✓ ϕ/π increases with multiplicity in pp/p-Pb → not expected for canonical suppression
  - ✓ ϕ/π saturates in Pb-Pb and is consistent with thermal model predictions, effective strangeness ~ 1-2
- ϕ is not expected to be modified in the hadronic phase at NICA energies and will serve as one of the key observables in the strange sector → need resonance measurements !!!

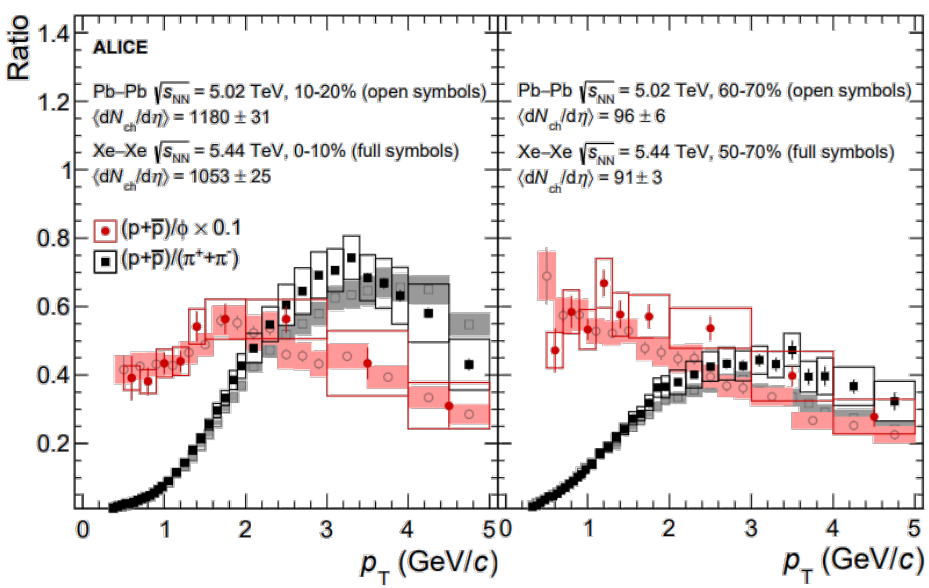
Enhanced baryon-to-meson ratios in A-A

Phys. Rev. C 101, 044907



- Enhanced baryon-to-meson ratios (p/π, Λ/K) in central heavy-ion collisions at intermediate p_T observed @ RHIC and the LHC → quark coalescence + flowing medium
- The bulk effect, not present in jets

arXiv:2101.03100

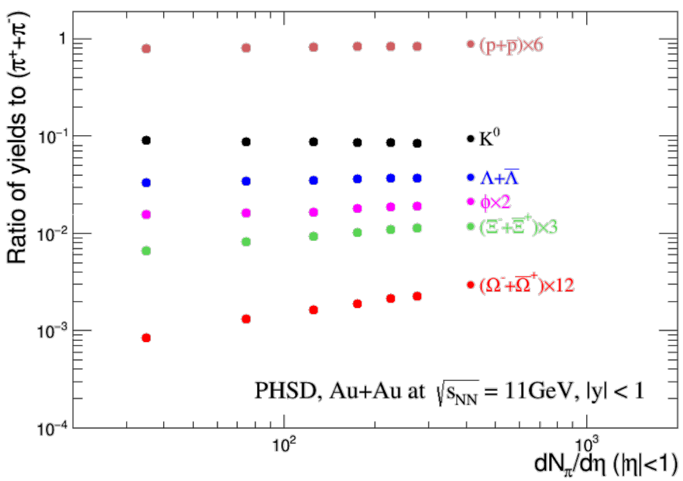


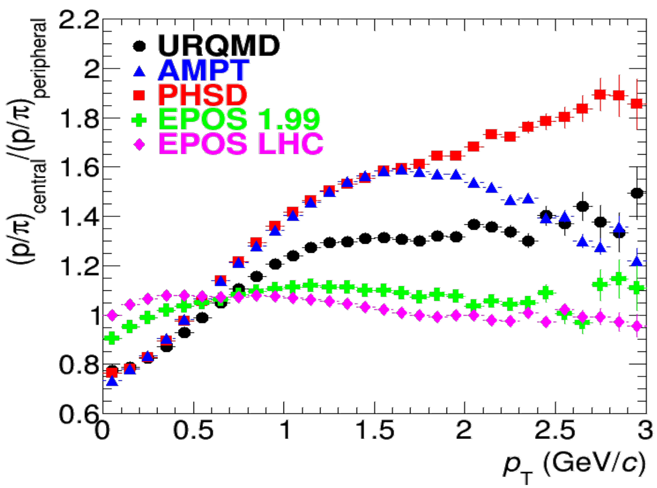
- p/ϕ ratio is almost constant vs. p_T at intermediate momenta in Pb-Pb and Xe-Xe collisions → spectral shapes are driven by particle masses:
  - ✓ consistent with hydrodynamics
  - ✓ recombination models are not ruled-out (V. Greco et al, PRC 92 054904 (2015))

Model predictions for resonances at NICA

❖ UrQMD, PHSD, AMPT, EPOS … AuAu@11

❖ General predictions:
  - ✓ models predict enhanced production of particles with strangeness
  - ✓ baryon/meson (B/M) ratios evolve with centrality/multiplicity and collision energy





❖ Eventually, model predictions (integrated yields, <p_T>, particle ratios etc.) should be compared to data to differentiate different model assumptions
