

Semileptonic Vector Boson Scattering at the ATLAS detector

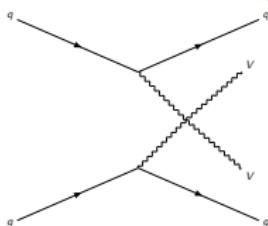

UK IoP Meeting 2021

Tobias Fitschen

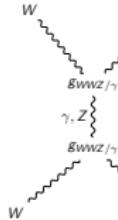

2021-04-12

Why study VBS?

Vector Boson Scattering (VBS)

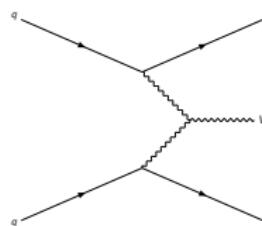

trilinear gauge coupling

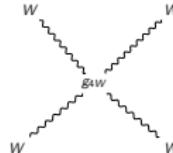

and

Vector Boson Fusion (VBF)

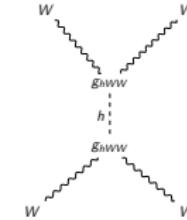

... are sensitive to:

quartic gauge coupling

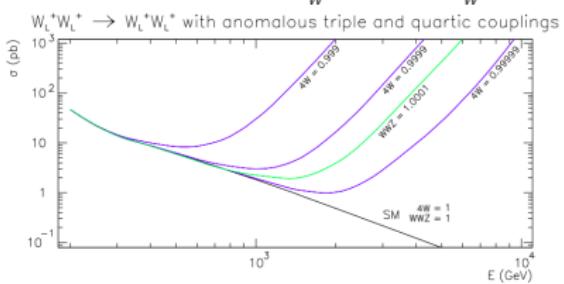

hVV coupling

Each diagram individually is divergent towards high energies

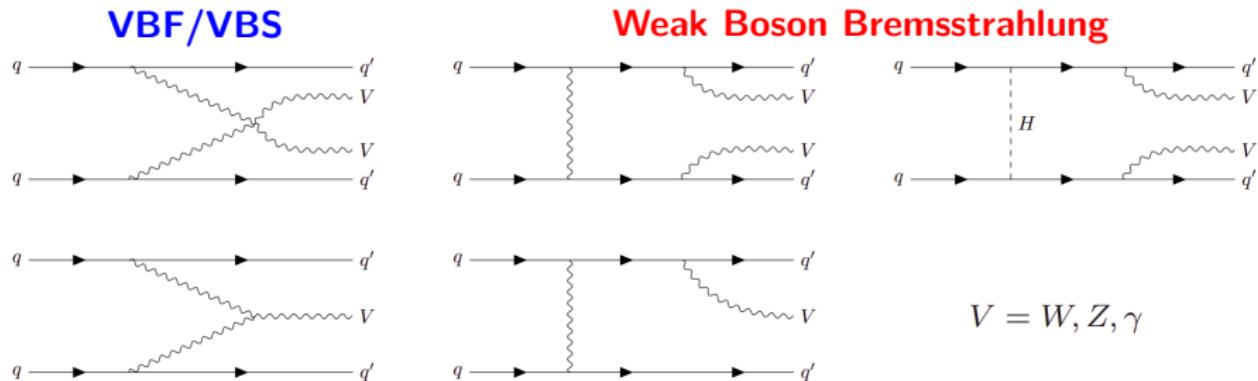

But divergences precisely cancel:

→ Highly sensitive probe for electroweak physics

There is no such thing as a VBS/VBF measurement on its own!

Gauge invariant set of Vjj / $VVjj$ diagrams at $\mathcal{O}(\alpha_W^3)$ / $\mathcal{O}(\alpha_W^4)$ tree level:

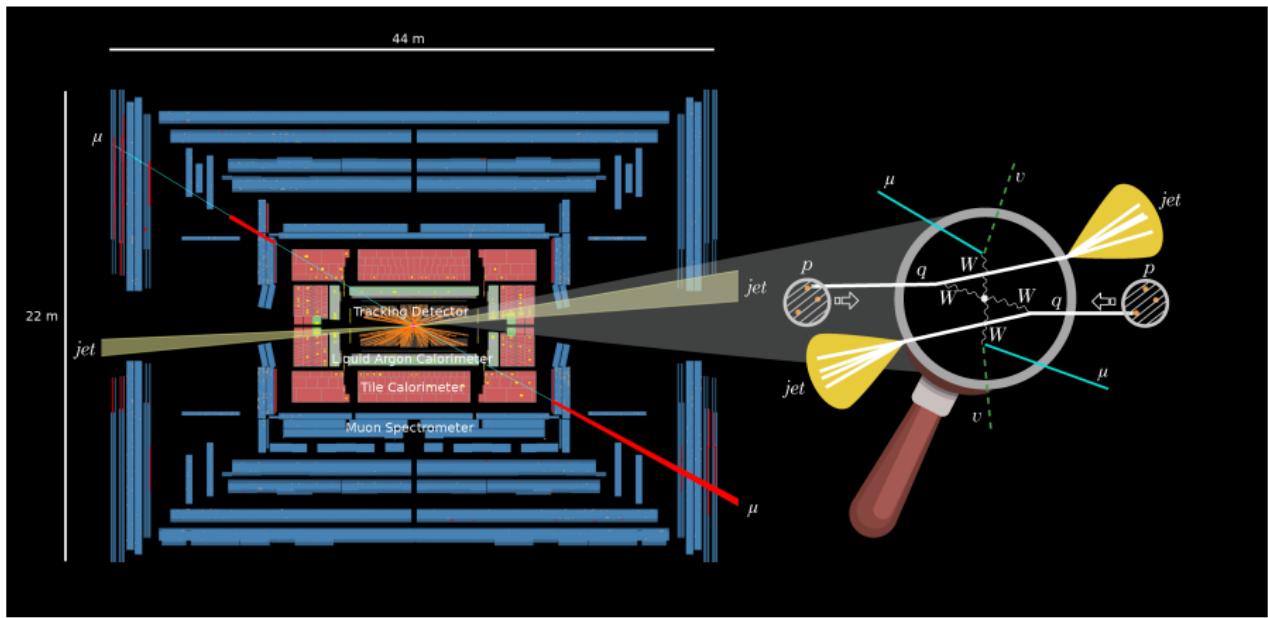

- Negative interference between VBS/VBF and weak boson bremsstrahlung
- Instead: measure **electroweak (EW) production of Vjj and $VVjj$**
- In this presentation: Semileptonic $VVjj$

The ATLAS Detector

Common experimental signature of VBS events:

- Dijet system jj with large invariant mass m_{jj}
- Different sides/hemispheres of the detector
- Large angular separation

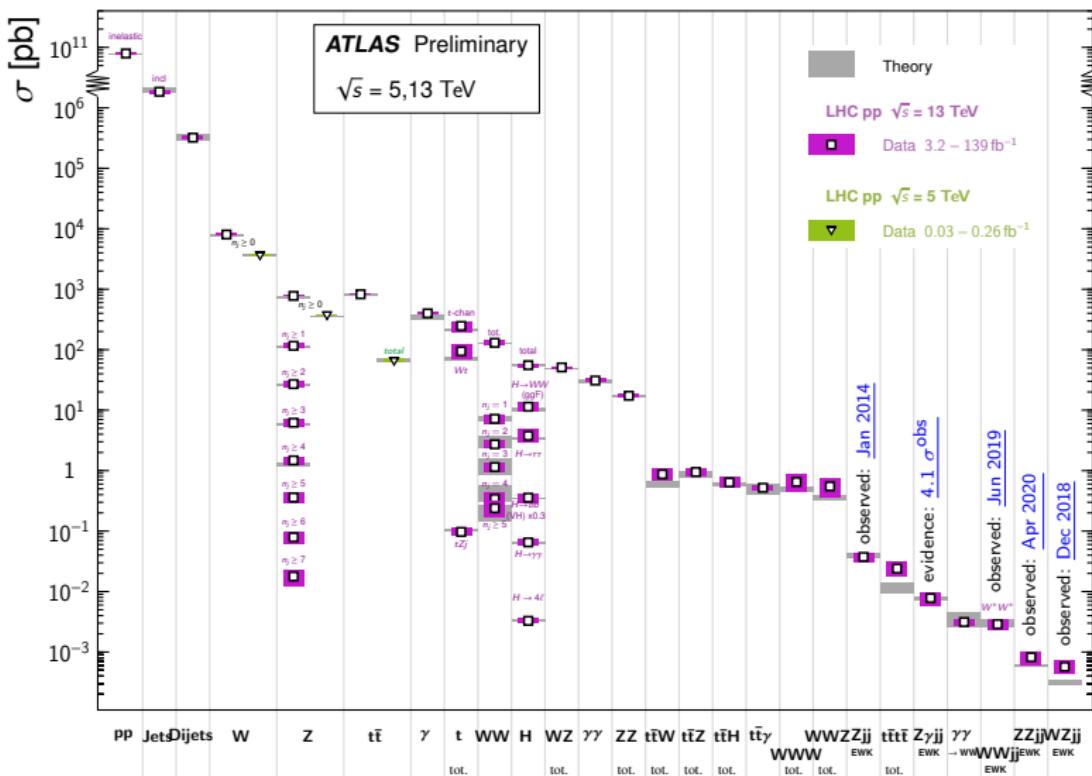

Simplified event display of a fully leptonic VBS candidate event in the ATLAS detector

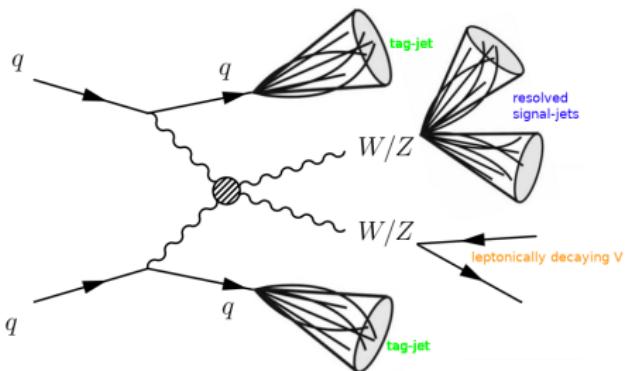

VBS/VBF at ATLAS

Standard Model Production Cross Section Measurements

Status: March 2021

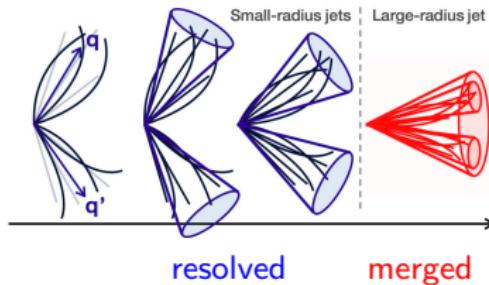

Semileptonic VBS

Final State:

- **2 tagging jets:**
Forward
Opposite Hemispheres
- **1 boson decays hadronically:**
 $2 R = 0.4$ signal jets (**resolved**)
or $1 R = 1.0$ signal jet (**merged**)

Analysis Goals:

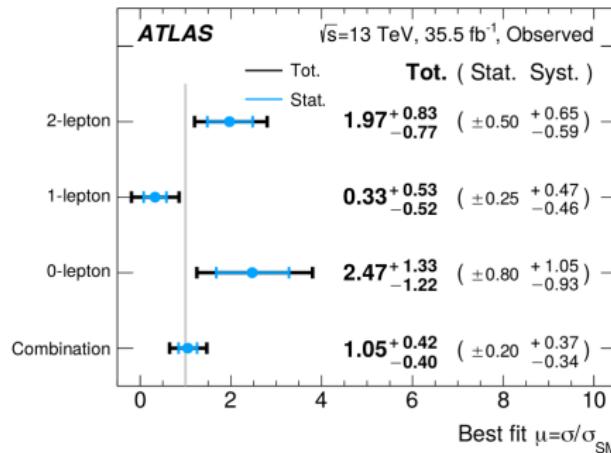

- Measure EW $VVjj$
- Cross-section in fiducial region
 - Differential if possible
- EFT interpretation
 - Search for aQGC
 - Sensitivity in high p_T needed

- **1 boson decays leptonically:**
0-lepton: $Z \rightarrow \nu\nu$
1-lepton: $W \rightarrow \ell\nu$
2-lepton: $Z \rightarrow \ell\ell$

Previous Analysis

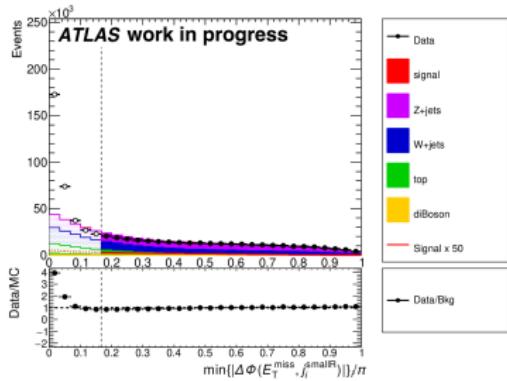

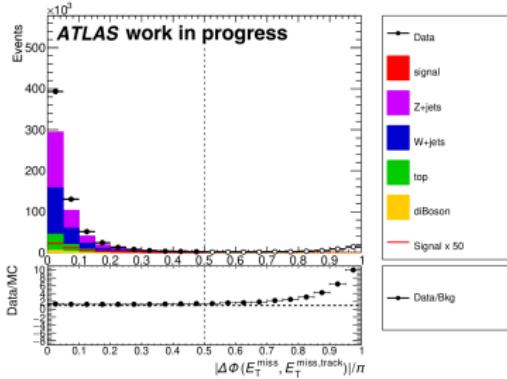

August 2019: Previous Analysis with 35.5 fb^{-1} : [Phys. Rev. D 100, 032007](#)

- Simultaneous max-likelihood fit on BDT outputs in all SRs and CRs
- Cross-section measurement in fiducial region

- Signal strength: $\mu_{\text{EWVvjj}}^{\text{obs}} = 1.05 \pm 0.20(\text{stat})^{+0.37}_{-0.34}(\text{syst})$
- Significance: $n_{\sigma}^{\text{obs}} = 2.7$, $n_{\sigma}^{\text{exp}} = 2.5$

0-Lepton Event Selection

Pileup reduction:

- Pileup affects tracker and calorimeters differently
 - Exclude events with small $E_T^{\text{miss,track}}$ magnitude
 - And with $E_T^{\text{miss,track}}$ in different direction in Φ than E_T^{miss}

QCD multijet rejection:

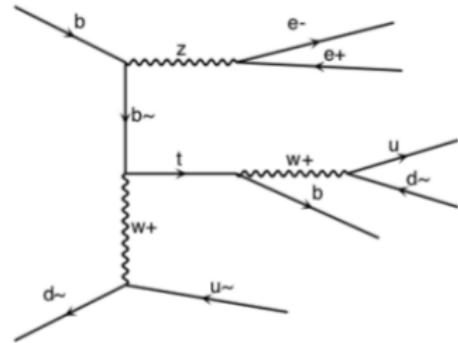

- No reliable Monte Carlo for QCD background available
- Must be reduced in data
- QCD events typically only pass E_T^{miss} selection if single mismeasured jet j contributes significantly to E_T^{miss}
 - Small distance $\Delta\Phi$ of j to E_T^{miss}

Signal composition

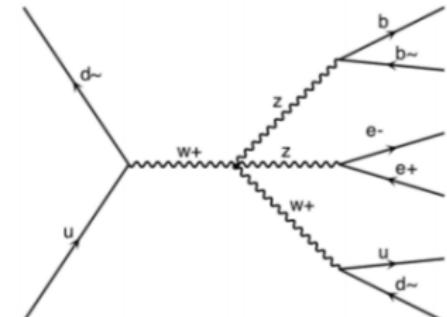

Two approaches for MVA final discriminant:

- **Baseline:** Full selection (tag jets & signal jets), multi variate analysis on high level variables
- **RNN approach:** Only signal-, no tag-jet selection, rely on recurrent neural network (RNN) with four-vecor input from all jets to distinguish VBS from non-VBS

Top processes

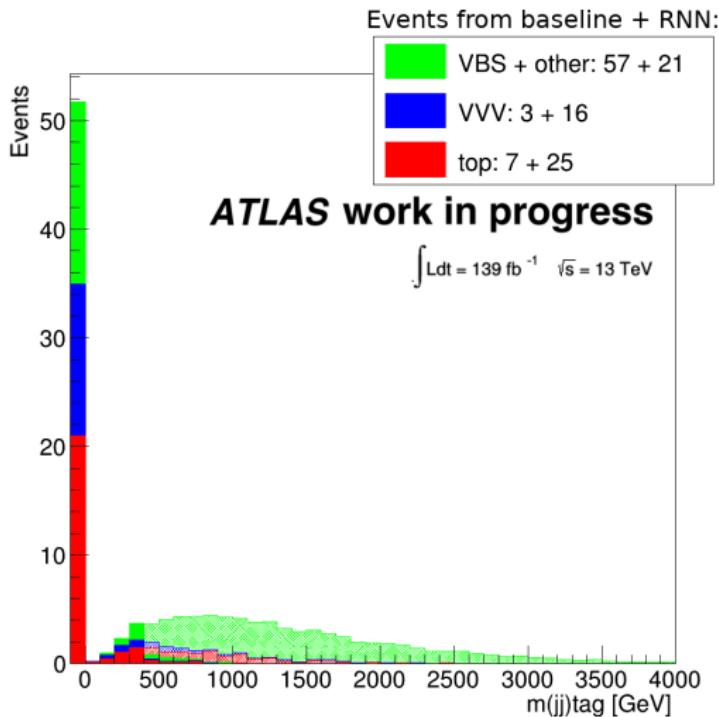

Triboson processes

Signal composition:

- Have to separate VBS processes from non-VBS EW VVjj
- Top and triboson processes large part of Monte Carlo signal sample
- Study contributions in baseline and RNN approach

Signal composition (in merged SR):

- **Hatched:** Baseline selection
 - **Filled:** Additional events from RNN approach (dropping tag-jet selection)
 - **Underflow bin:** No two tagging jets reconstructed
- Most events added by RNN approach do not have reconstructed tag-jets

Summary & Outlook

Semileptonic Vector Boson Scattering at the ATLAS detector

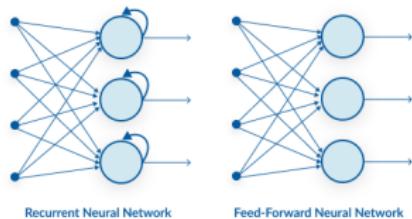

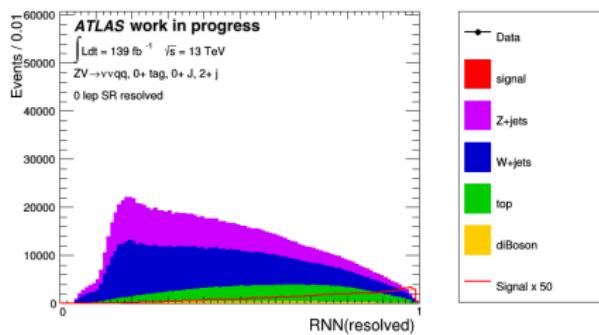

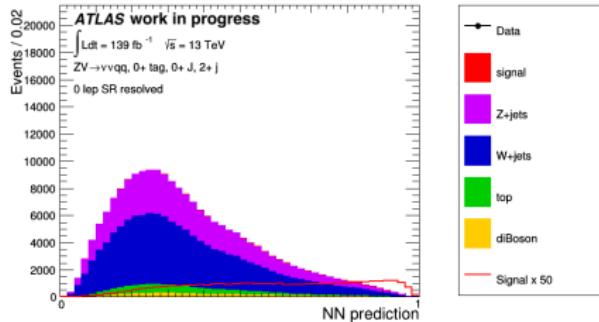

Summary:

- Previous analysis significance: $n_{\sigma}^{\text{obs}} = 2.7$ at 35.5 fb^{-1}
- **New study with 139 fb^{-1} in progress:**
 - Cross section measurement of semileptonic EWK VVjj in fiducial region
 - aQGC study with EFT approach in progress
 - Studies on signal composition (VBS/ non-VBS contributions)
- **Two approaches for MVA final discriminant:**
 - **Baseline:** full selection (tag jets & signal jets) and then BDT or NN
 - **RNN approach:** only signal-, no tag jet selection, then RNN
 - Novel RNN approach must be verified against baseline

Goal:

- Obtain 5 sigma observation of the VBS process in semileptonic final state

Additional Material

Baseline selection MVA:

- Simple feed-forward NN
- Using high-level input variables
- Tag-jet selection for VBS-like events
- But some VBS-like events lost by this

No-tag selection RNN:

- Dropping selection on j^{tag}
 - Full jet four-vectors as inputs in addition to high level variables
 - Recurrent architecture (RNN) allows variable input length
- Here: Each event has a different number of jets
- Rely on RNN to learn VBS-specific jet configuration

Fiducial Selection:

Object definition:

- ℓ^{good} : μ/e^{truth} with $p_T > 20 \text{ GeV}$ and $|\eta| < 2.5$
- ℓ^{veto} : μ/e^{truth} with $p_T > 7 \text{ GeV}$ and $|\eta| < 2.5$
- R=.4 jets $j: j^{\text{truth}}$ with $(p_T > 20 \text{ GeV} \text{ and } |\eta| < 2.5) \text{ or } (p_T > 30 \text{ GeV} \text{ and } |\eta| < 4.5)$ and $\Delta R(\ell^{\text{good}}) > 0.2$
- R=1. jets $J: J^{\text{truth}}$ with $p_T > 200 \text{ GeV}$ and $|\eta| < 2$
- b-labeled jet $j_b: j$ with 'HadronConeExclTruthLabelID' = 5
- tag jets: highest-mass (jj) system from all j with $\text{eta}(j_1) * \text{eta}(j_2) < 0$ and not b-labeled
- resolved sig jets $(jj)^{\text{sig}}$: two leading $p_T j$ excluding jj^{tag}
- merged sig jet J^{sig} : leading- $p_T J$ with $\Delta R(j^{\text{tag}}) > 1.4$

Channel selections:

- 0-lepton:
 - $E_T > 200 \text{ GeV}$
 - $= 0 \ell^{\text{veto}}$
 - 0 or 2 b-tagged j^{sig} , no other
- 1-lepton:
 - $E_T > 80 \text{ GeV}$
 - $= 1 \ell^{\text{good}}$
 - $p_T(\ell^{\text{good}}) > 27 \text{ GeV}$
 - no b-labeled jets
- 2-lepton:
 - $= 2 \ell^{\text{good}}$
 - $p_T(\ell^{\text{good}}_{\text{lead}}) > 28 \text{ GeV}$
 - $p_T(\ell^{\text{good}}_{\text{sub-lead}}) > 20 \text{ GeV}$
 - 0 or 2 b-labeled j^{sig} , no other

Regime Definitions:

- merged: J^{sig} has $64 < m < 106 \text{ GeV}$
- resolved: $(jj)^{\text{sig}}$ has $64 < m < 106 \text{ GeV}$ and $p_T(J^{\text{sig}}_{\text{lead}}) > 40 \text{ GeV}$

Selection order (VBSFidType):

VBSFidType	channel	regime
0	0-lepton	merged
1	0-lepton	resolved
2	1-lepton	merged
3	1-lepton	resolved
4	2-lepton	merged
5	2-lepton	resolved

Tag jet selection (passFidMjjTag):

- p_T of both $j^{\text{tag}} > 30 \text{ GeV}$
- $m(jj)^{\text{tag}} > 400 \text{ GeV}$

Number of signal events after various extra selections to reduce non-VBS signal:

baseline selection:

selection	merged HP SR				merged LP SR				resolved SR			
	events	% fid.	% t	% V	events	% fid.	% t	% V	events	% fid.	% t	% V
nominal	68	43	10	4	114	40	12	5	1339	23	28	5

nominal+bVetoExcl+bVetoSig+topMass	77	34	7	13	125	32	8	14	894	24	13	11

Extra cuts:

- **topMass:** $m_t > 200 \text{ GeV}$ where m_t : mass of $(jj)^{\text{sig}} + \text{additional jet (triplet closest to SM top mass)}$
- **bVetoExcl:** no $R = .4$ jet (excl. sig jets) b-tagged
- **bVetoSig:** == 0 or 2 signal jets b-tagged

Fractions:

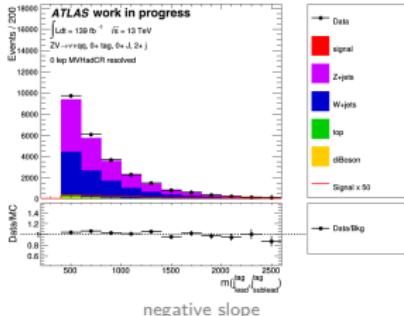

- **% fid:** Fraction of events passing fiducial selection (resolved + merged combined)
- **% t:** Fraction of events that have a top in the diagram (truth info)

Reweighting

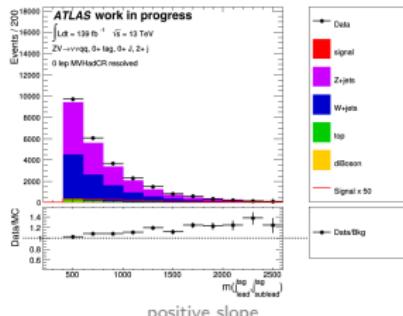

$m(jj)^{\text{tag}}$ reweighting in 0-lepton:

- Well-known mismodeling in Sherpa W/Z+jets samples
- Common issue among VBS/VBF analyses
- $m(jj)^{\text{tag}}$ reweighting derived in 1-lepton/2-lepton (W/Z) CR too strong for 0-lepton
- Independently deriving W and Z reweightings in 0-lepton CR reduces slope substantially

no reweighting

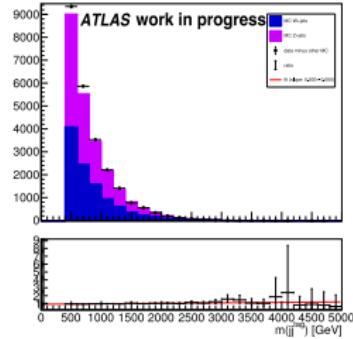

reweighting from 1/2-lep

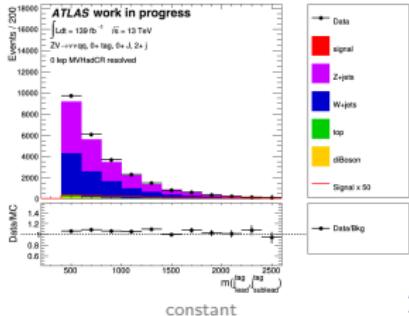

Procedure:

Fit ratio of W/Z+jets to data - all other MC

reweighting from 0-lep

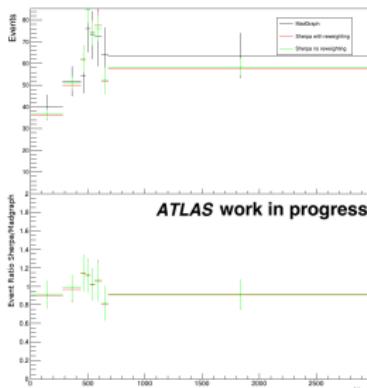

Shape systematics (0-lepton):

- Shape systs. from ratio of shape in Sherpa (nominal) and MadGraph (syst)
- Normalized to MadGraph
- Rebinned (from right to left: merge bins with < 50 events)
- Two options: With and without $m(jj)$ reweighting in Sherpa

W+jets:

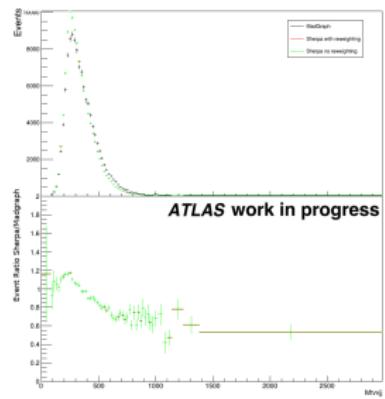

merged HP SR

merged LP SR

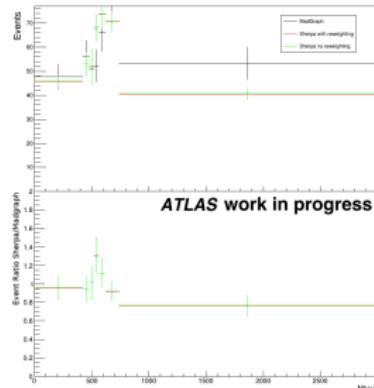

resolved SR

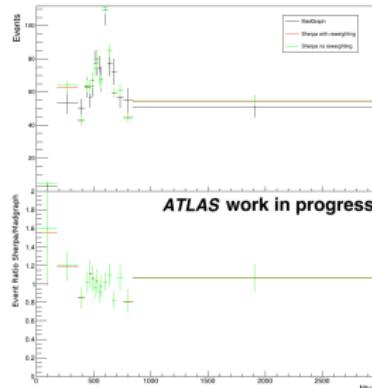

Shape systematics (0-lepton): Z+jets:

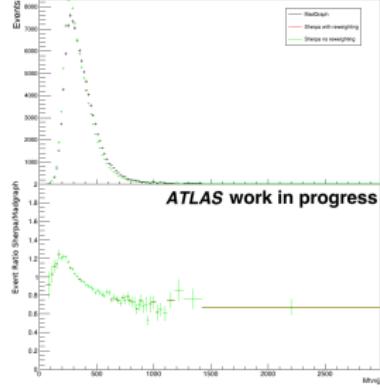

merged HP SR

merged LP SR

resolved SR

VBS MC with aQGC EFT according to [Eboli Model](#):

- 3 scalar (FS), 10 tensor (FT), and 8 mixed (FM) operators
- [MadGraph implementation](#)
- Simulate $pp \rightarrow VVjj$, use MadSpin for V decays
- Adding simulated EFT contrib. to SM template

Object Definition: Jets

Small-R-jets j :

- EMPFlow
- AntiKt with $R = 0.4$
- $p_T(j) > 20 \text{ GeV}$

Large-R-jets J :

- LCTopo
- AntiKt with $R = 1.0$
- $p_T(J) > 200 \text{ GeV}$
- Trimmed with $f_{\text{cut}} = 5.0$,
 $R_{\text{sub}} = 0.2$ (Kt-reclustering)

Track-jets j^{track} :

- From PV0-Tracks
- AntiKt with $R = 0.2$

Tagging Jets $(jj)^{\text{tag}}$:

- dijet small-R-jet system jj with:
- $\Delta\eta(jj) < 0$
- $\max(m_{jj})$

Signal jets $(jj)^{\text{sig}}$:

- dijet small-R-jet system jj with:
- $\min(|m_{W/Z} - m_{jj}|)$
- selected after tagging jets

Signal fat jet J^{sig} :

- leading p_T large-R-jet J
- with $\Delta R(J, j^{\text{tag}}) > 1.4$

B-tagging:

- MV2c10 algorithm
- $\epsilon = 70\%$ working point (in $t\bar{t}$)

Object Reconstruction:

- e: isolated clusters in EMcal matched to ID tracks
 - $E_T > 7 \text{ GeV}$
 - $|\eta| < 2.47$
 - {loose,medium,tight} id to separate from hadrons
- μ : combined fit from MS and ID
 - $p_T > 7 \text{ GeV}$
 - $|\eta| < 2.5$
 - {loose,medium,tight} id from #hits in ID and $|\frac{q}{p_{MS}} - \frac{q}{p_{ID}}|$
- $I(e,\mu)$ isolation:
 - from $\sum p_T$ of tracks in p_T -dep. cone around I
- jets: EMPFlow($R=0.4$)+LCTopo($R=1.0$)
- b-tagging for j at 70% (in $t\bar{t}$), rejection factor: 380(L), 12(C)
- $j(R=0.4)$:
 - $p_T > 20 \text{ GeV}$ at $|\eta| < 2.5$, $p_T > 30 \text{ GeV}$ at $2.5 < |\eta| < 4.5$
 - vertex tagger PU supr. for j with $p_T < 60 \text{ GeV}$ and $|\eta| < 2.5$
- $J(R=1.0)$:
 - $p_T > 200 \text{ GeV}$, $|\eta| < 2.0$
- $j^{\text{track}}(R=0.2)$ ($\#j^{\text{track}}$ used as BDT input):
 - $p_T > 20 \text{ GeV}$, $|\eta| < 2.5$
- E_T^{miss} : neg. vectorial sum of $p_T(e, \mu, j)$
- p_T^{miss} : neg. vectorial sum of all good ID tracks assoc. to PV

Overlap Removal:

- j removed if $\Delta R(j, e) < 0.2$
- e removed if $0.2 < \Delta R(j, e) < 0.4$
- j removed if $\Delta R(j, \mu) < 0.2$ and (j has < 3 tracks or small $\Delta E, p(j, \mu)$)
- μ removed if $0.2 < \Delta R(j, \mu) < 0.4$
- J removed if $\Delta R(J, e) < 1.0$
- no overlap removal between J , j , and j^{track}

W/Z tagging (in J):

- p_T dependent requirement on $D_2^{(\beta=1)}$
- must be in p_T dependent window around m_{boson}
- working points of 50% and 80%

Electroweak Zjj (VBS):

- Leptonic decay: $\rightarrow \ell^+ \ell^- jj$ ($\ell = e, \mu$)
- 8 TeV [paper](#) (20.3 fb^{-1}):
5 σ observation
- First 13 TeV [paper](#) (3 fb^{-1}):
Fiducial cross-section
- Current 13 TeV [paper](#) (139 fb^{-1}):

Differential x-sec measurement:

- With respect to 4 observables: $m(jj)$, $|\Delta y(jj)|$, $\Delta\Phi(jj)$, $p_T(\ell\ell)$
- Short term goal: Gives handle on which MC Generator models VBS/VBF most reliably
- Long term goal: Provides input for MC generator improvement

Search for anomalous weak-boson self-interactions:

- EFT approach
- Limits on 4 dim. 6 operators producing anomalous WWZ interactions

Electroweak ZZjj (VBS):

- 13 TeV [paper](#) (139 fb^{-1}):

Final states: $\rightarrow lllljj$ and $ll\nu\nu jj$

Combined: 5.5σ

One of the smallest cross-sections
measured in ATLAS!

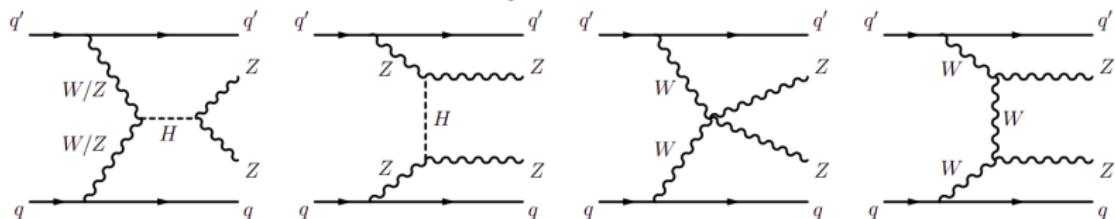

significance of EW Zjj:

	Significance Obs. (Exp.)
$lllljj$	$5.5 (3.9) \sigma$
$ll\nu\nu jj$	$1.2 (1.8) \sigma$
Combined	$5.5 (4.3) \sigma$

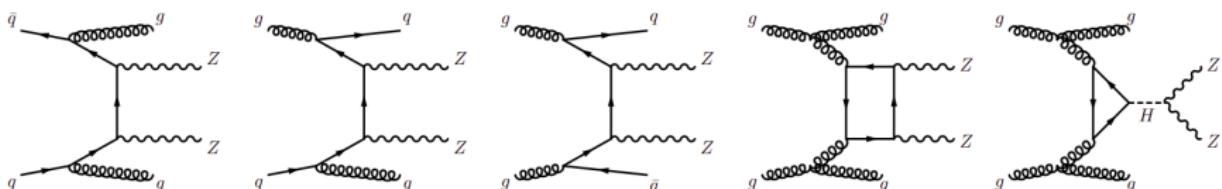

measured cross-section:

$$\sigma_{\text{EW}}^{\text{ZZjj}} = 0.82 \pm 0.21 \text{ fb}$$

EW production:

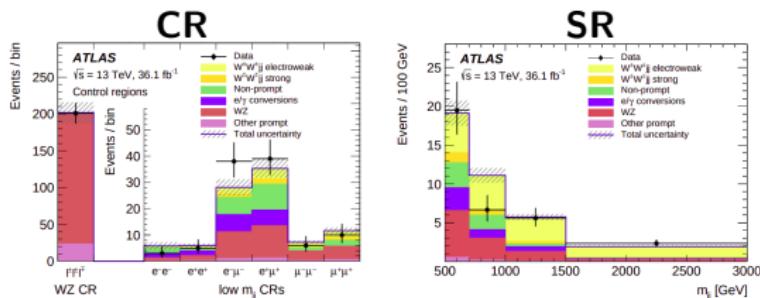

strong production:

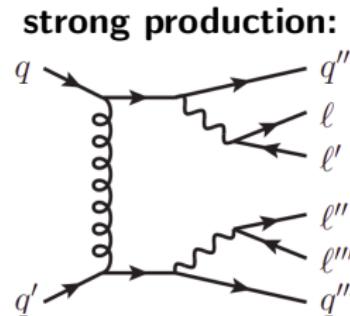

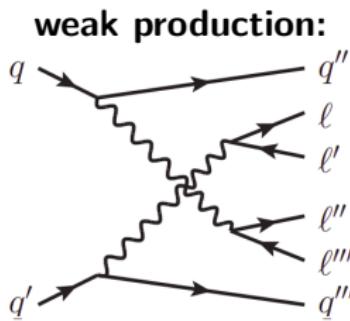

EW WWjj same sign (VBS):

- $W^\pm W^\pm jj$ has largest ratio of EW/QCD cross-section among VBS diboson
- Strong production not the dominant background
- 8 TeV [paper](#) (20.3 fb^{-1}):
Evidence: 4.5σ
- 13 TeV [paper](#) (36.1 fb^{-1}):
observation: 6.5σ
fid. cross-section: $\sigma_{\text{EW}}^{W^\pm W^\pm jj} = 2.89 \text{ fb}$

- 6 channels: $e^\pm e^\pm$, $\mu^\pm \mu^\pm$, $e^\pm \mu^\pm$
 \Rightarrow 6 SRs ($\times 4$ bins) + 6 m_{jj} CRs + WZ CR

Non-prompt leptons bkg:

- ℓ from heavy-flavour hadrons
- Jets misidentified as e
