【105】 Directly imaged non-standing spin-waves in rectangular microstrips under uniform excitation

Tuesday, August 31, 2021 2:30 PM (15 minutes)

In this contribution we present direct imaging of spin-wave dynamics in $\text{Ni}_{80}\text{Fe}_{20}$ rectangular microstrips ($5 \times 1 \times 0.03 \mu\text{m}^3$) under uniform excitation. Both a single strip and two strips of the same size oriented perpendicular to each other are investigated. For FMR and time-resolved STXM measurements a static magnetic field is applied in plane, aligned parallel or perpendicular to the longer side of the strips. The measurements confirm that quasi-uniform and spin-wave excitations can be observed in these geometries. Increasing the static magnetic field allows to observe the spin-waves at resonance fields and their superposition off resonance. A non-standing character of spin waves under uniform excitation is reported. Financial support by FWF (P.Nr.:I-3050).
