

# Motivations of a Muon Collider for the Higgs sector

Carlo Rubbia

INFN and Gran Sasso Science Institute, L'Aquila, Italy

CERN, European Organization for Nuclear Research, Geneva, CH

# Premise

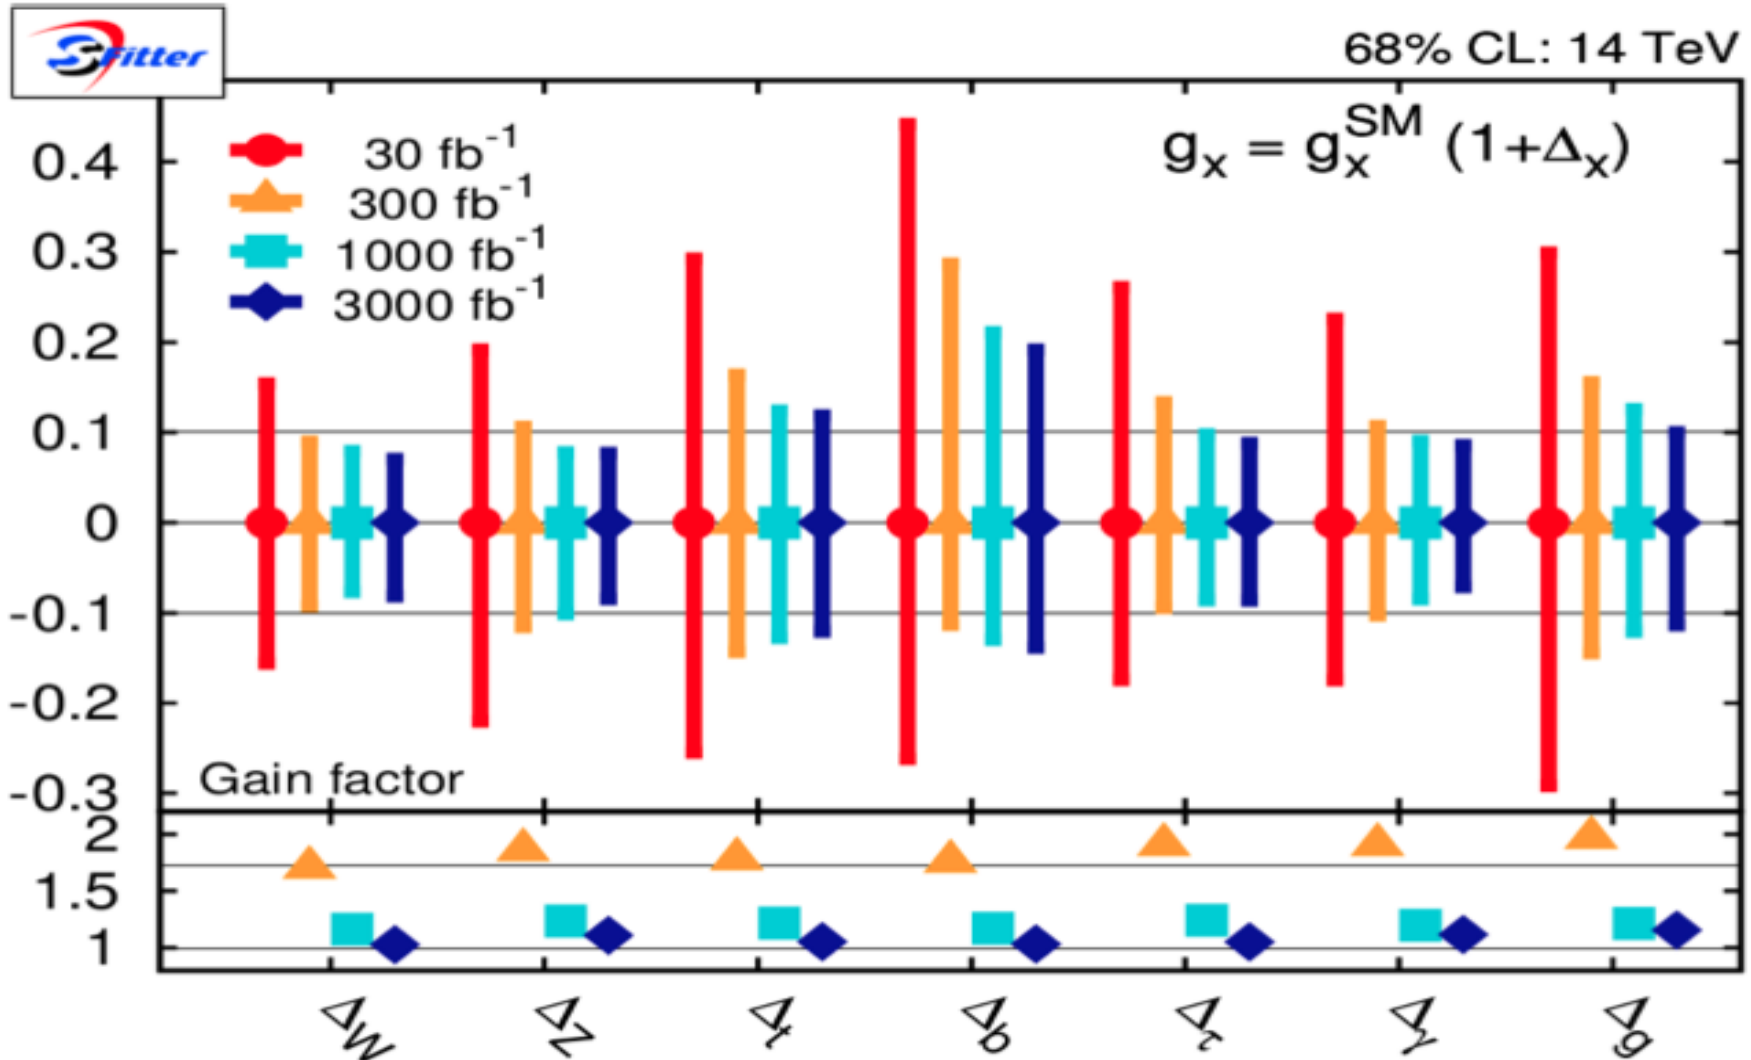

- The *Standard Model* of particle physics is a monumental description of three of the four fundamental forces in the Universe (electromagnetic, weak, and strong interactions), as well as classifying all known elementary particles.

# The Higgs sector

- The LHC is an essential future program for the Higgs physics. See for instance CERN-LPCC-2018-04 : *Higgs Physics at the HL-LHC and HE-LHC*. (femtobarn =  $10^{-39}$ , attobarn =  $10^{-42} \text{cm}^2$ )
- The integrated luminosity for the HL-LHC is  $3000 \text{ fb}^{-1} = 3 \text{ ab}^{-1}$  at 14 TeV. A subsequent HE-LHC higher energy program may follow with a dataset assumed to be  $15 \text{ ab}^{-1}$  at 27 TeV.
- However "per se", in spite of its huge progress, HL-LHC, even if followed by HE-LHC, requires also other further extensions
- While the  $Z_0$  and  $W$ 's are **vectors**, the Higgs is a **scalar (spin = 0)**, characterized by a much stronger coupling when initiated from muons rather than from electrons.
- The Higgs sector ( $H_0$ ) — no doubt — should follow the previously well-known observations of the  $Z_0$  and the  $W$ 's, where the initial search and discovery with the  $P$ - $P$ bar collider had been followed by the systematic lepton studies with LEP.

# Expected LHC gain factors as a function of the rate

For 3000 fb<sup>-1</sup>, LHC estimates are expected to improve only by a factor less than a factor 2.

# The need of a better precision

- What precision is needed in order to search for possible additional deviations from the SM, even under the assumption that there is no other additional "Higgs" state at the LHC ?
- Predicted typical LHC accuracies for "exotic" alternatives

<i>R.S. Gupta et al.</i>	$\Delta hVV$	$\Delta h\bar{t}t$	$\Delta hbb$
Mixed-in Singlet	6%	6%	6%
Composite Higgs	8%	tens of %	tens of %
Minimal Supersymmetry	< 1%	3%	10% <sup>a</sup> ,
LHC 14 TeV, 3 ab <sup>-1</sup>	8%	10%	15%

← Ultimate st.dev. at LHC

$$\frac{g_{hbb}}{g_{h_{SM}bb}} = \frac{g_{h\tau\tau}}{g_{h_{SM}\tau\tau}} \simeq 1 + 1.7\% \left( \frac{1 \text{ TeV}}{m_A} \right)^4$$

SUSY  $\tan(\beta) > 5$

$$\frac{g_{hff}}{g_{h_{SM}ff}} = \frac{g_{hVV}}{g_{h_{SM}VV}} \simeq 1 - 3\% \left( \frac{1 \text{ TeV}}{f} \right)^2$$

Composite Higgs

$$\frac{g_{hgg}}{g_{h_{SM}gg}} \simeq 1 + 2.9\% \left( \frac{1 \text{ TeV}}{m_T} \right)^2, \quad \frac{g_{h\gamma\gamma}}{g_{h_{SM}\gamma\gamma}} \simeq 1 - 0.8\% \left( \frac{1 \text{ TeV}}{m_T} \right)^2$$

Top partners

- Sensitivity to "TeV" new physics for "5 sigma" discoveries may need 1 per-cent to sub 1-per-cent  $\sigma$  accuracies on standard dev.

# New huge $e^+ e^-$ rings proposals, several times the LHC.

*LEP3, TLeP,  
FNAL site-filler +, , , ,*

*Options for circular  $e^+ e^-$ -  
Higgs factories are becoming  
popular around the world*

# Conventional e+e- Ring or Linear Collider ?

- Several e+e- projects have been described in huge new tunnels. Either (a) a relatively conventional *Collider Ring* and (b) a *Linear Collider (ILC)* are possible.
- As (a) we quote the FCC-ee from CERN of 100 km ( $3.7 \times$  LEP), in the Geneva area.
- The study comprises a 90-400 GeV e+e- machine (FCC-ee) and a 100 TeV p-p collider (FCC-hh) with also heavy ions and of e-p
- Alternative (b) of a Linear Collider (ILC) is a major new technology, Two bunches of 5 nm ( $0.005 \mu\text{m}!$ ), each with  $2 \times 10^{10}$  particles are colliding 14'000 times per second.

# The Linear Collider option

- The International Linear Collider (ILC) is a high-luminosity linear electron-positron collider based on 1.3 GHz superconducting radio-frequency (SCRF) accelerating technology
- Its energy  $\sqrt{s}$  is 200-500 GeV (extendable to 1 TeV)

*ILC, CLIC, NLC, JLC +...*

*The total footprint for 500 GeV is ~31 km. To upgrade the machine to  $E_{cms} = 1$  TeV, the linacs and the beam transport lines would be extended by another ~ 22 km up to 53 km*

# The muon collider as an optimal alternative

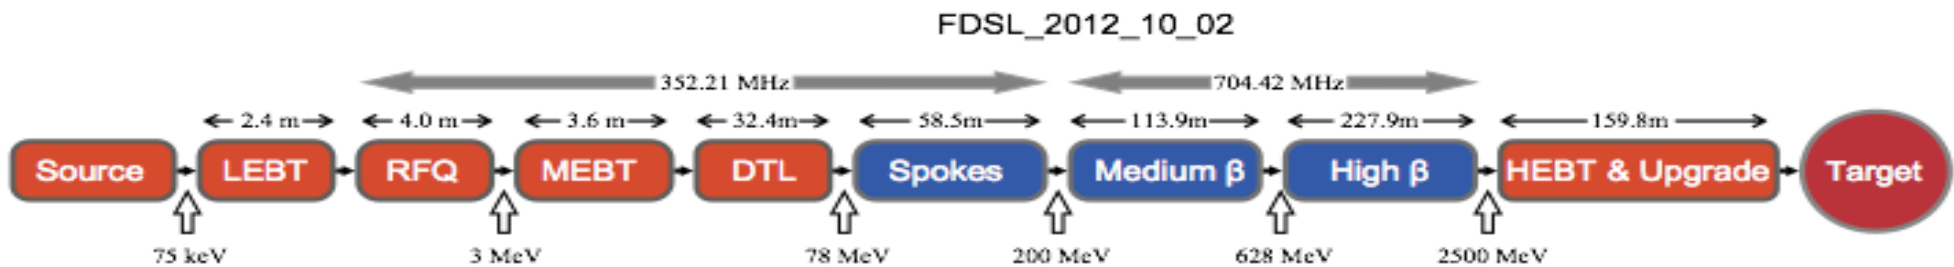

- Muons combine a "point-like" electron-like nature with a larger mass immune to radiation.
- **A  $\mu^+\mu^-$  collider** is therefore highly preferable because of its small dimension that permits the utilization of an existing site.
- However it demands substantial R&D in order to produce adequate compression in 6D phase space of the muon beams.
- To this effect an initial experimental program based on a small Cooling Ring should be first carried out.
- Based on the reasonable extension of the European accelerator programs — for instance either at ESS and/or at CERN — it would consist of two subsequent steps: an **initial Cooling Experiment** and the **subsequent Main Experiment**
- The realization of the main  $H^0$ -factory could be constructed only after the success of the initial cooling experiment has been confirmed at a lower cost.

# Early activities in the USSR and in the US

- "Ionization Cooling" was first proposed by Budker and by Skrinsky in the 60's and early 70's. However, there was little substance until Skrinsky and Parkhomchuk developed the idea.
- The initial ideas in the US were presumably due around 1980 to Cline and Neuffer. A Snowmass feasibility study has been organized in 1996 and a US collaboration with DOE organization and funding has been formed in 1997.
- As discussed already in 1994 for instance by Barletta and Sessler, muons may be produced by the two classes of processes:
  - (A) *production from protons, subsequently decaying into muons*
  - (B)  *$\mu^+\mu^-$  pairs from electro-production.*
- During the following two decades Neuffer, Palmer, Cline and many others have greatly expanded ionization cooling of process (A).
- These have been very important developments, but only very few verifying experimental tests have been performed.

# A future Muon Collider program for Europe

- Several other accelerator programs at higher energies for  $\mu^+\mu^-$  factories have been described in the US (both BNL and FNAL) and elsewhere, **but requiring substantial intensity improvements.**
- Amongst the many LHC upgrade programs which have been discussed, CERN had considered the HP-HPL, a H- beam at 5 GeV kinetic energy with 50 Hz, 4 MWatt and  $1.0 \times 10^{14}$  p/ pulse.
- However in 2010 CERN has decided on different alternatives and HP-HPL project has been cancelled. **ESS remains the main option.**
- The **European Spallation Source**, now in construction in Lund, with 5 MWatt of protons accelerated to a kinetic energy of 2 GeV at 14 Hz and  $1.1 \times 10^{15}$  p/p can be extended to provide intensity and repetition rate for the presently discussed collider program.

# Main future muon Higgs alternatives

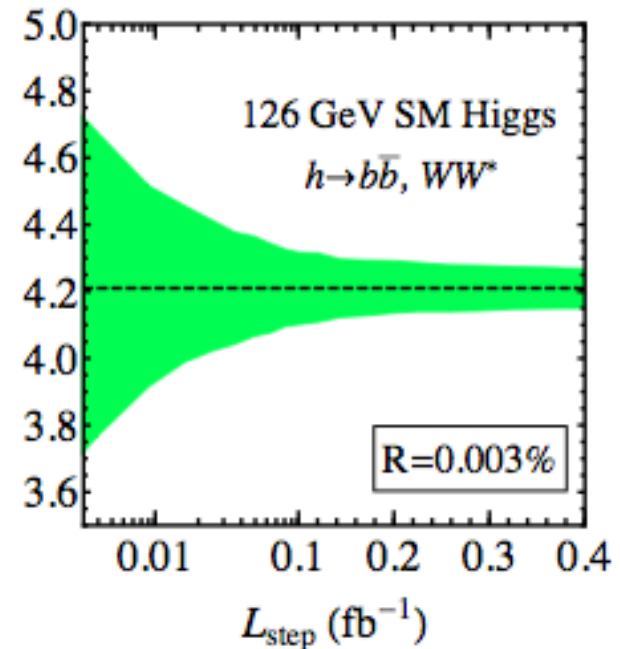

- Two adequate Higgs alternatives of a  $\mu^+ \mu^-$  collider will be discussed:
  - the s-channel resonance at the  $H_0$  mass, to study with  $\approx 40'000$  fb and  $L > 10^{32}$  all decay modes with small backgrounds;
  - A higher energy collider, eventually up to  $\sqrt{s} \approx 0.5-1$  TeV and  $L > 10^{34}$  to study all other Higgs processes of the scalar sector.
- The colliding beams ring can easily fit within existing locations:
  - For  $\sqrt{s} = 126$  GeV the ring *radius is  $\approx 50$  m* (about 1/2 of the CERN PS or 1/100 of LHC) but with the *resolution  $\approx 0.003\%$*
  - For  $\sqrt{s} = 0.5$  TeV the corresponding ring *radius is  $\approx 200$  m* (about twice the CERN PS) and the *resolution  $\approx 0.1\%$*
- Two  $\mu^+ \mu^-$  bunches of  $2 \times 10^{12}$  ppp can likely be produced by a high pulsing rate of a few GeV protons at  $\approx 5$  MWatt.

# $\sqrt{s} = 125.5 \text{ GeV}$ : the Higgs muon resonance

- Signals and backgrounds for  $H \rightarrow WW^*$ , and  $bb$  with energy resolution  $R = 0.003\%$ . with a Gaussian energy spread  $\Delta = 3.75 \text{ MeV}$  and  $0.05 \text{ fb}^{-1}/\text{step}$  and with detection efficiencies included.
- Effective pb at the  $\sqrt{s}$  resonance for two resolutions  $R$  and with the SM branching fractions =  $H \rightarrow bb$  56% and  $WW^* = 23\%$

R (%)	$\mu^+ \mu^- \rightarrow h$ $\sigma_{\text{eff}}$ (pb)	$h \rightarrow b\bar{b}$		$h \rightarrow WW^*$	
		$\sigma_{\text{Sig}}$	$\sigma_{\text{Bkg}}$	$\sigma_{\text{Sig}}$	$\sigma_{\text{Bkg}}$
0.01	16	7.6	15	3.7	0.051
0.003	38	18		5.5	

# Comparing $\mu+\mu^-$ and $e+e^-$ at the $H_0$ resonance peak

- The narrow  $H_0$  width may be quantified convoluting the Breit-Wigner resonance with a gaussian Beam Energy Spread (BES) and the Initial State Radiation (ISR) QED effects.
- The  $\mu+\mu^-$  cross sections are 71 pb for resonance profile alone and of 10 pb and 22 pb with both BES and ISR and energy resolutions  $R = 0.01\%$  and  $R = 0.003\%$ . (picobarn =  $10^{-36} \text{ cm}^2$ )
- The  $e+e^-$  cross sections are 0.15 fb for both the BES and ISR effects and  $R = 0.01\%$ .
- In these conditions ( $R = 0.01\%$ ) the  $\mu+\mu^-$  rate is  $\approx 10'000$  times the  $e+e^-$  rate.

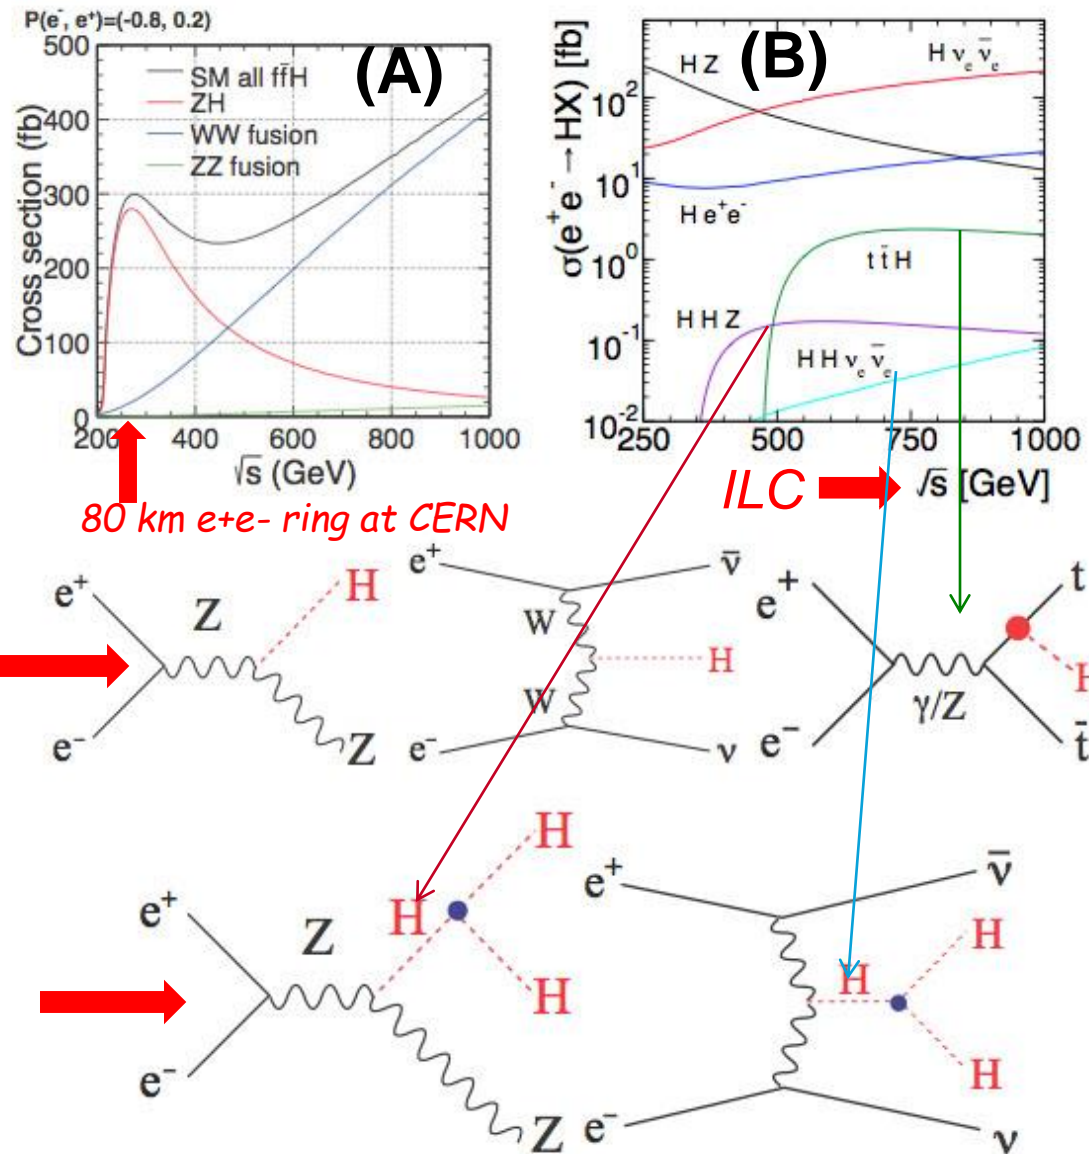

Huge BES and ISR corrects

# Studies at the Ho peak are not entirely sufficient:

We need in addition :

- (A) Production cross sections of WW, ZZ, ZH fusion from  $e^+e^-$  as a function of  $\sqrt{s}$
- (B) Production cross sections from  $e^+e^-$  or  $\mu^+\mu^- \rightarrow H + X$  as a function of the  $\sqrt{s}$  energy
  - The Higgs-strahlung diagram (Left), the W-boson fusion process (Middle) and the top-quark association (Right).
  - Double Higgs boson diagrams via off-shell Higgs-strahlung (Left) and W-boson fusion (Right) processes.

*Lepton energies up to  $\approx 0.5 - 1$  TeV are necessary*

# The realization of an Initial Cooling Experiment

- Physics requirements and the studies already undertaken with muon cooling suggest that a next step, prior to but adequate for a specific physics programme *could be the practical realization of an appropriate cooling ring demonstrator.*
- Indicatively this corresponds to the realization of an unconventional *tiny ring of 20 to 40 meters circumference* in order to achieve the theoretically expected longitudinal and transverse emittances of asymptotically cooled muons.
- The injection of muons from pion decays could be coming from some existing accelerator at a reasonable intensity.
- The goal is to prove experimentally the full 3D cooling.
- The other facilities, namely (1) the pion/muon production, (2) the final, high intensity cooling system (3) the subsequent muon acceleration and (4) the accumulation in a storage ring could be constructed later and only after the success of the initial cooling experiment has been confirmed at a lower cost.

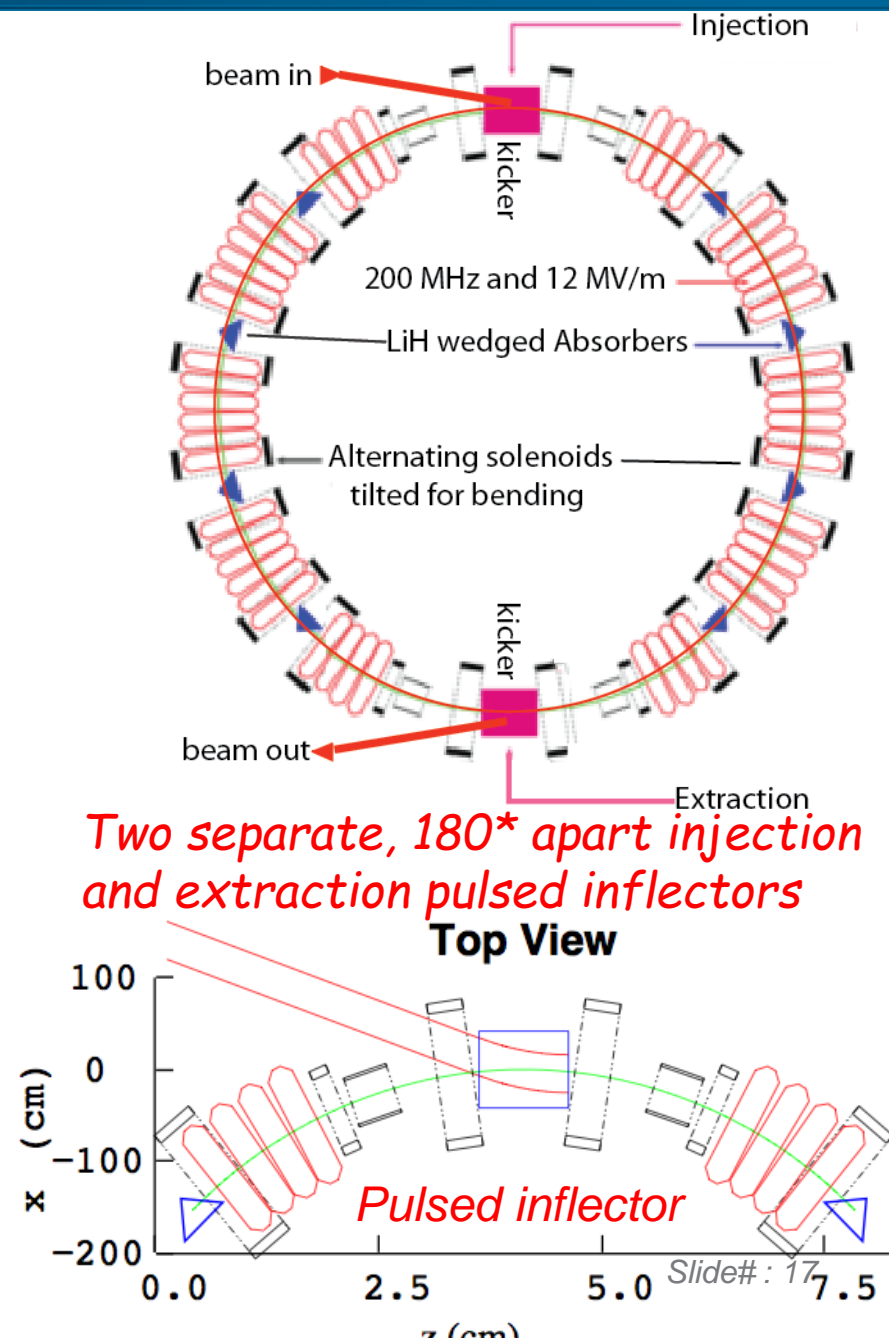

# RFOFO Ionization Cooling

- The design is based on solenoids tilted in order to ensure also bending. The LiH absorbers are wedge shaped to ensure longitudinal cooling.

Circumference	33	m
Total number of cells	12

# A solenoid-dipole ring cooler for a muon collider

- Another exemplificative cooling ring is the one of Garren et al. (NIM, A 654 (2011) 40-44).
- Injection/extraction kickers are used in a straight section; a superconducting flux pipe is used for the injected beam.

Parameters of the four-sided and achromatic ring cooler.

Momentum (MeV/c)	220
Superperiods	4
Number of dipoles	32
Number of straight solenoids	16
Number of arc solenoids	16
Arc length (m)	6
Straight section length (m)	5
Dipole length and field	0.2 m, 0.72,045 T
Dipole bend and edge angles (deg.)	11.25, 2.8,125
Arc solenoid length and field	0.25 m, 3.38,290 T
Straight section solenoid length and field	0.25 m, 2.91,555 T
Superperiod length and xytunes	11 m, 1.75
Circumference (m)	44

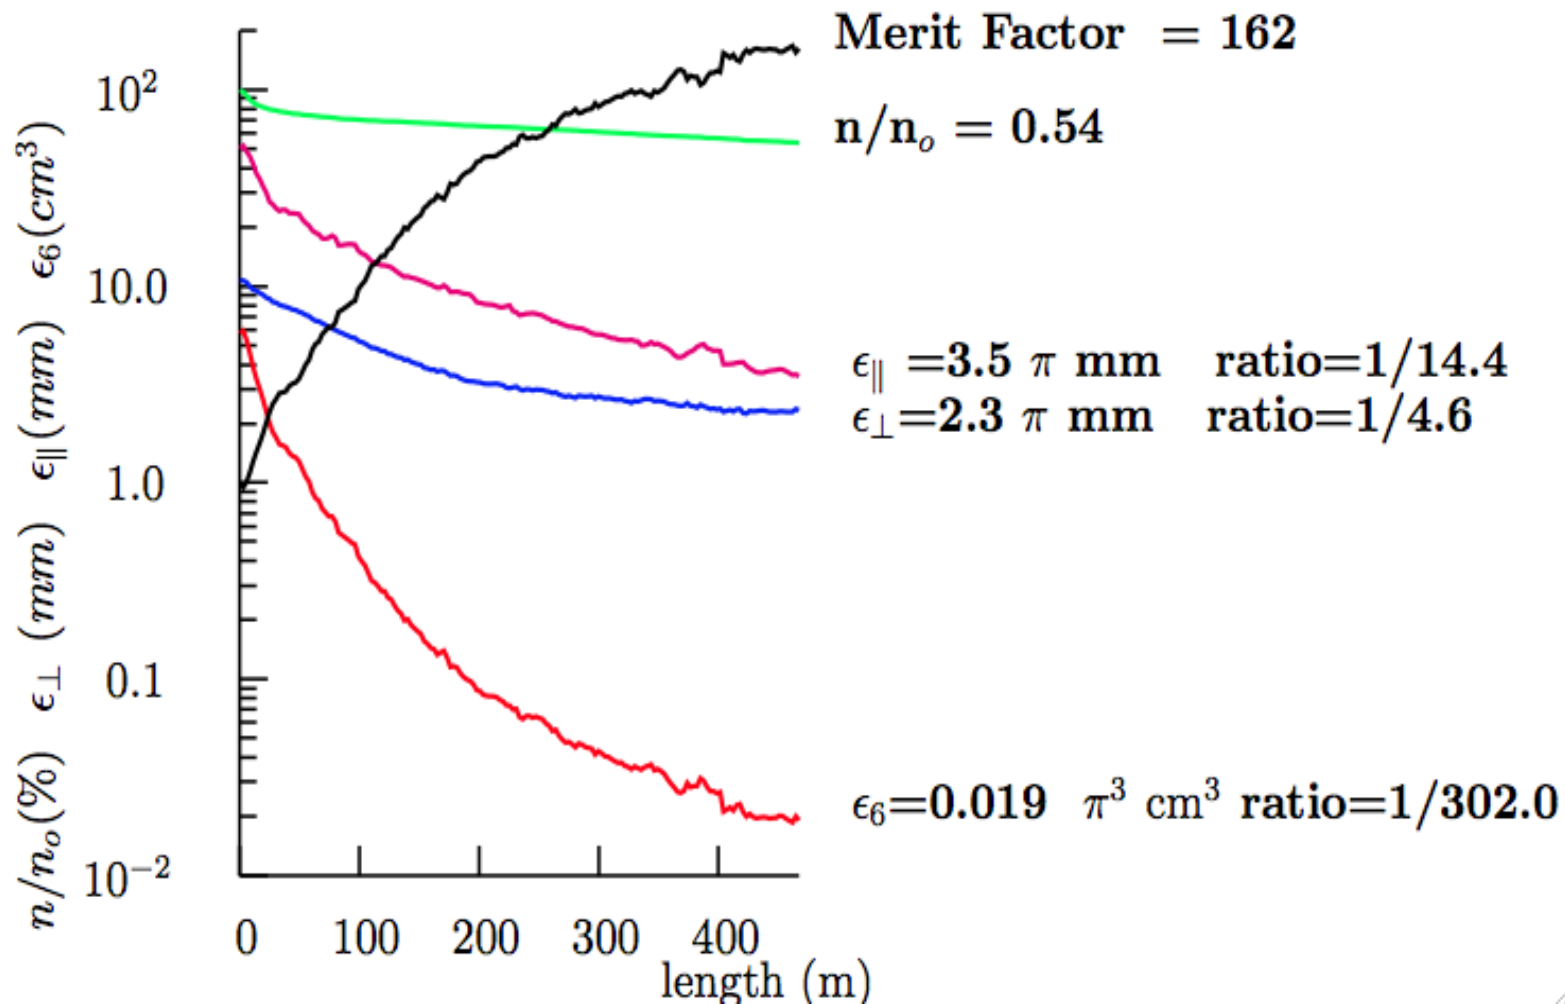

# Properties of a “RFQFO” Cooling Ring

- The muon emittances of the RFQFO ring after the first linear rotation may be  $e_{v,H} = 20 (\pi)$  mm rad and  $e_L = 30 (\pi)$  mm rad with a r.m.s. energy spread is about 10 %.
- After cooling, the ultimate normalized hydrogen driven equilibrium emittances at 250 MeV/c are expected to be  $e_{v,H} = 0.4 (\pi)$  mm rad and  $e_L = 1.0 (\pi)$  mm rad.
- This corresponds to the huge 6D compression factor of  $50 \times 50 \times 30 = 75'000$ , i.e. a Merit Factor  $M = (Initial\ 6D)/(final\ 6D) \times transmission$  of the order of  $15'000 = 75'000/5$  with a total number of muons due to decay losses of a factor 5.
- In an estimated “RFQFO” Cooling Ring, a merit factor of 162 had been observed after 16 turns of the ring.
- Doubling the number of turns of the RFQFO cooling ring will ensure the required compression to attain the required equilibrium of emittances after the first linear rotation .

# A remarkable merit factor

- Predicted merit factor of a "RFOFO" Cooling Ring after 16 turns and a muon survival of 54% (Palmer et al.)

# The Main Program

- **Three successive steps** are required in order to bring the cooling process at very low energies, after capture and bunching + rotation.

1. Linear transverse cooling of both signs and small  $\Delta p$  increase.
2. Ring cooling in 6D with B brings the  $\mu+$  and  $\mu-$  to a reasonable size Merging and cooling to single bunches.
3. Parametric Resonance Cooling (PIC), where the elliptical motion in  $x-x'$  phase space has become hyperbolic.

## Step 2.- The 6-D cooling

- The linear initial muon processing facilitates the further subsequent injection in a cooling ring.
- Secondary protons are removed by an absorber and two cooling rings separate the charges. A wedge absorber is placed such that high momenta pass through more material than low momenta, so that all three dimensions can be cooled.
- The initial several bunches of each sign can be initially cooled and later, at an intermediate stage, bunch rotated and each accumulated in one bunch which is extracted at the end of the cooling process.
- The wedge has a central thickness of 28 cm, a total wedge opening angle of  $100^\circ$  and is rotated  $30^\circ$  from the vertical to match the maximum of the dispersion.

# Step 3.- PIC, the Parametric Resonance Cooling

- Ionization cooling: adding a **second parametric resonance ring** is expected to lead to a beam with much smaller transverse sizes.
- A linear magnetic transport channel has been designed by Ya.S. Derbenev et al. where a **half integer resonance** is induced such that the normal elliptical motion of particles in  $x-x'$  phase space becomes **hyperbolic**, with particles moving to smaller  $x$  and larger  $x'$  at the channel focal points.
- Thin absorbers and RF placed at the focal points of the channel then cool the angular divergence by the usual ionization cooling.

*LEFT ordinary oscillations  
RIGHT hyperbolic motion  
induced by perturbations  
near an (one half integer)  
resonance of the betatron  
frequency.*

# Details of PIC

- Without damping, the beam dynamics is not stable because the beam envelope grows with every period. Energy absorbers at the focal points stabilize the beam through the ionization cooling.
- The longitudinal emittance is maintained constant (with RF) by tapering the absorbers and placing them at points of appropriate dispersion, vertical  $\beta$  and two horizontal  $\beta \times \sigma$ .
- Cooling factors (ratio of initial to final 6D emittance) with and without the PIC vs number of cells: **about 10x gain**

# Bunch acceleration to 62.5 GeV

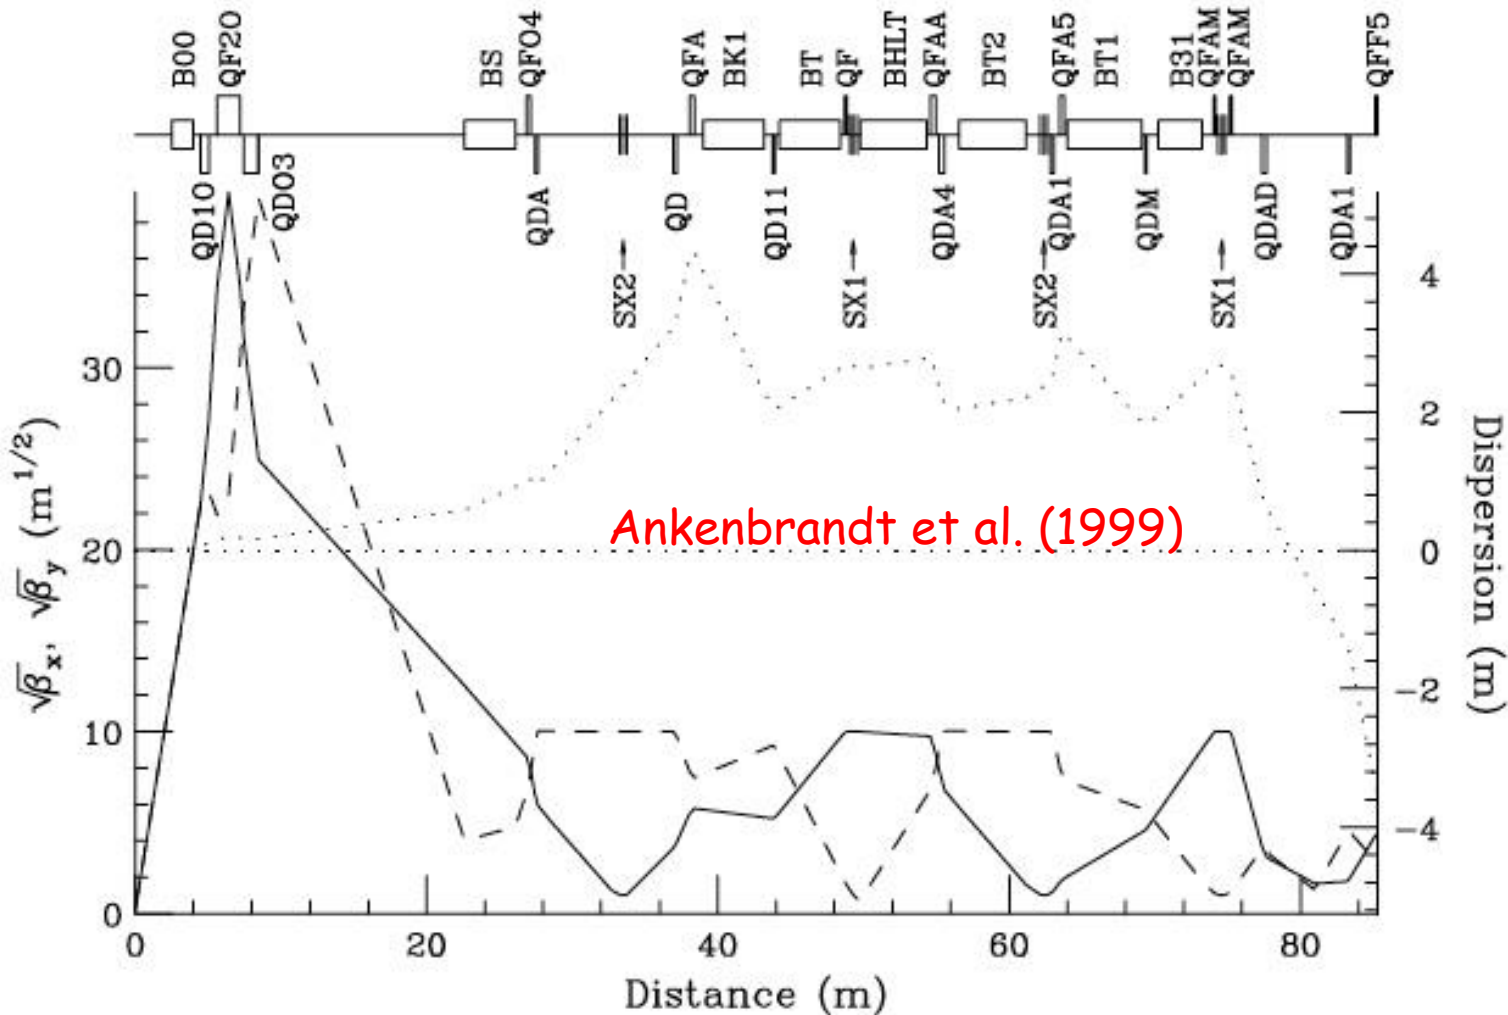

- Next, in order to realize a Higgs Factory at the known energy of 126 GeV, an acceleration system is progressively rising the energy of captured muons to  $m_{H_0}/2$
- Adiabatic longitudinal Liouvillian acceleration to  $p_f = 62.5 \text{ GeV}/c$ .
- Both  $\mu^+$  and  $\mu^-$  are accelerated sequentially in the same LINAC with opposite polarity RF buckets
- Two recirculating LINAC and 25 MeV/m with f.i. 5 GeV energy/step with 4 bi-directional passages to 63 GeV ( $\approx 200 \text{ m}$ )
- A similar layout for the second phase with  $\sqrt{s} \approx 0.5 \text{ TeV}$  will require twice the passages and recirculating lengths (400 m)

*D. Neuffer, 2013*

# Muons collide in a storage ring of $R \approx 60$ m

- Lattice structure at the crossing point, including local chromaticity corrections with  $\beta_x = \beta_y = \beta^* = 5$  cm.

# Comments on the cooling process

- A conventional muon cooling ring should present no unexpected behaviour and good agreement between calculations and experiment is expected both transversely and longitudinally
- The novel Parametric Resonance Cooling (PIC) involving instead the balance between a strong resonance growth and ionization cooling may involve significant and unexpected conditions which are hard to predict. Reported predictions are for  $\approx 10^{10}$  p/bunch
- Therefore the experimental demonstration of the cooling must be concentrated on such a resonant behaviour
- On the other hand, the success of the novel Parametric Resonance Cooling may be a premise for an optimal luminosity, since the expected Higgs rate is proportional to the inverse of the transverse emittance
- PIC may expect up to one order of magnitude transverse emittance decrement

# Luminosity

- The luminosity is given by a formula where: 
$$L = f \frac{N^+ N^-}{4 p e_{rms} b}$$
  - $N^+ = N^- = 2.5 \times 10^{12} \mu/\text{pulse}$
  - $f$  is the number of effective luminosity crossings:  $43 \times 555 = 23'865/s$
  - $\varepsilon_{rms} = \varepsilon_N / 589.5 = 0.36 \times 10^{-4} \text{ rad cm}$ , with  $H_2$
  - $\beta^* = 5 \text{ cm}$  is beta at crossing in both dimensions
- Luminosity is  $L = 5 \times 10^{31} \text{ cm}^{-2} \text{ s}^{-1}$  at each collision crossing
- The cross section at the maximum folded with a  $\Delta E = 3.4 \text{ MeV}$  is  $1.0 \times 10^{-35} \text{ cm}^2$ . Hence the Ho event rate is  $1.2 \times 10^4$  events for  $10^7 \text{ s/y}$ . In 10 y and two crossings: 1/4 million Ho events (without PIC)
- With a successful novel Parametric Resonance Cooling (PIC),  $\varepsilon_{rms}$  is reduced by a factor 10 with  $1.2 \times 10^5$  events/year/i.p.

# Estimated performance for the H<sup>0</sup>-factory (ESS)

- Two asymptotically cooled  $\mu$  bunches of opposite signs collide in two low-beta interaction points with  $\beta^* = 5$  cm and a free length of about 10 m, where the two detectors are located.
- **With PIC cooling** a peak collider a luminosity of  $4 \times 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$  is achieved
  - The bunch transverse rms size is 0.05 mm and the  $\mu$ - $\mu$  tune shift is 0.086.
  - The SM Higgs rate is  $\approx 10^5$  ev/year ( $10^7$  s) in each of the detectors.
  - An arrangement with at least two detector positions is recommended.

Proton kinetic energy	2.0	GeV

**Without PIC**  
 **$1.2 \times 10^4$  ev/year**

# Conclusions

- All the described activities may fit within the existing ESS site or eventually at CERN or elsewhere (China).
  - *proton accumulator and compressor rings* with a radius of **35 m**, transforming from 14 to 42 bunch/s;
  - A  $\pi - \mu$  *linear decay channel* with both muon signs of about **100 m** length converting muons to 250 MeV/c and  $\Delta p/p$  at  $\pm 10\%$ ;
  - a pair of robust  $\mu^+$  and  $\mu^-$  *ionization-cooling rings* each with  $\approx$  **6 m** radius, compressing to two narrow bunches, eventually followed by two additional PIC cooling rings;
  - a fast *re-circulating LINAC acceleration* system of about **few hundred m** to bring muons to both required collision energies;
  - a *collider ring at 7 Tesla and*  $\approx$  **50 m** radius for  $\sqrt{s} = 126$  GeV (1) and  $\approx$  **200 m** for  $\sqrt{s} = 0.5$  TeV (2) with two two narrow muon bunches and two interaction points where detectors are located with  $\approx 2 \times 10^{12}$  muons/pulse of each sign.

**12'000 Higgs/y @  $10^7$  s/y without PIC**

# Muon related backgrounds

- A major problem is caused by muon decays, namely electrons from  $\mu$  decay inside the detector with  $\approx 2 \times 10^3$  e/meter/ns, however collimated within an average angle of  $10^{-3}$  rad.
- A superb collimation is required with the help of absorbers in front of the detector's straight sections. *This is an open problem*

*Drozhdin, Mokhov et al.*

# The Higgs muon collider

## ● Advantages

- Large cross sections  $\sigma(\mu^+\mu^- \rightarrow h) = 41 \text{ pb}$  in  $s$ -channel resonance and  $\mu^+\mu^- \rightarrow ZH$  of  $0.2 \text{ pb}$  at  $\sqrt{s} = 500 \text{ GeV}$ .
- Small size footprint: it may fit within an existing site
- No synchrotron radiation and beamstrahlung problems
- Precise measurements of line shape and decay widths
- Exquisite measurements of all channels and tests of SM
- The cost of the facility, provided cooling will be successful, is likely to be less than 1/10 of one of the LHC

## ● Challenges.

- A low cost demonstration of muon cooling must be done first
- Muon 2D and 3D cooling needs to be fully demonstrated
- Need ultimately very small c.o.m energy spread (0.003%)
- Backgrounds from constant muon decay
- Significant R&D required towards end-to-end design
