

# Options for alternate radiators for LHCb-RICH system

*CERN: Mini-Workshop on gas transport parameters  
for present and future generation of experiments*

On behalf of LHCb-RICH group

S.Easo  
22-04-2021

# Outline

- Studies done by Olav Ullaland
- Start of investigations to use CO<sub>2</sub> in RICH2
- Impact of potential usage of SiPM in the future
- Exploring non-gaseous radiators
- Summary

# Investigations in the past

*From O. Ullaland*

Is there a future for  
the LHCb RICHes  
without  
perfluorocarbons?

Anthropogenic and Natural Radiative Forcing. In: Climate Change 2013: The Physical Science Basis.

*From O. Ullaland*

Table 8.A.1 | Radiative efficiencies (REs), lifetimes/adjustment times, AGWP and GWP values for 20 and 100 years, and AGTP and GTP values for 20, 50 and 100 years. Climate-carbon feedbacks are included for CO<sub>2</sub> while no climate feedbacks are included for the other components (see discussion in Sections 8.7.1.4 and 8.7.2.1, Supplementary Material and notes below the table; Supplementary Material Table 8.SM.16 gives analogous values including climate-carbon feedbacks for non-CO<sub>2</sub> emissions).

**Global Warming Potential (GWP)**

**Absolute Global Warming Potential (AGWP)**

Chemical Formula	GWP 20-year	Chemical Formula	GWP 20-year	Chemical Formula	GWP 20-year

CCl <sub>2</sub> FCClF <sub>2</sub>	6490	HCF <sub>2</sub> O (CF <sub>2</sub> CF <sub>2</sub> O) 3CF <sub>2</sub> H	9050		

Only molecules with an atmospheric lifetime longer than 20 years have been retained from this publication.

Please note:  
The Global Warming Potential is given relative to CO<sub>2</sub> which is set to be 1.  
LHCb RICH friends are indicated in **red**.

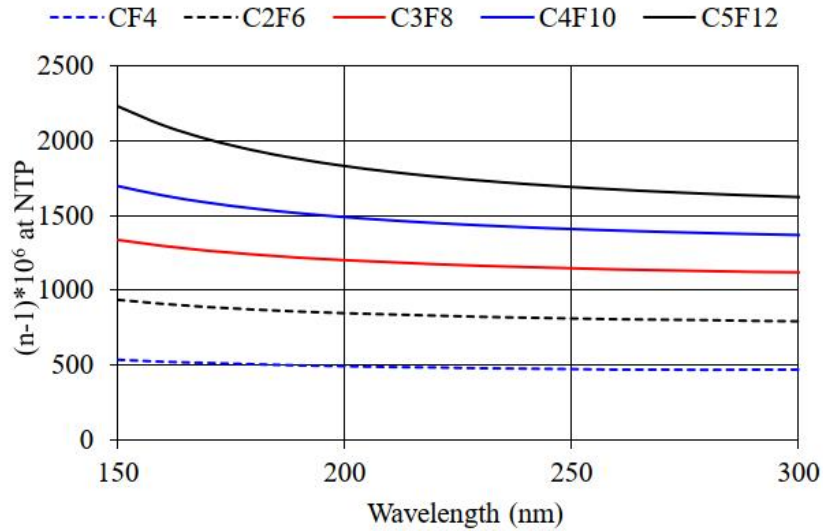

No uncertainties are given for these values in the publication. They should therefore be taken as indicative and not as absolute values.

C<sub>4</sub>F<sub>8</sub>O is also ruled out, since it has a large GWP 12000 (100-year time horizon).

# Investigations in the past

From O. Ullaland

## Fluorocarbon gases : RICH1

Assuming that we are not looking for a reduction of a few percent in the Global Warming Potential, but rather a factor of 10 (or even better 100),

then we are not too far off from a correct working point with a  $C_3H_8$  gas.

+ CH<sub>4</sub>/0.0541/89.3 + C<sub>2</sub>H<sub>6</sub>/0.0922/90.1 + C<sub>2</sub>H<sub>4</sub>/0.0527/114.6  
 × C<sub>3</sub>H<sub>8</sub>/0.1277/91.6 × C<sub>3</sub>H<sub>6</sub>/0.0795/113.4

It has some (minor) drawbacks:

$C_3H_8$

Flash point  
 Autoignition  
 temperature  
 Explosive limits

-104 °C (169 K)  
 470 °C (743 K)  
 2.37–9.5%

Propane: cooking gas

## Hydrocarbon gases : RICH1

# Investigations in the past

*From O. Ullaland*

$C_4F_{10}$  vs  $C_4H_{10}$  : RICH1

$C_4H_{10}$  :

Depending on where you want to be, you get a little higher n-1 with Isobutane.

$C_4H_{10}$ :

- Isobutane : GWP = 3.3
- Used as a refrigerant

Risk of explosion

But you might still find that the CERN Safety Commission is blocking your goal.

# Investigations in the past

## Gases without Carbon

*From O. Ullaland*

These gases would require a pressurized container which is somewhat sub-optimal. (for RICH1 )

$$(n-1) \propto \frac{P}{T}$$

*For RICH2, it would be a very low pressure container, which is also not a good idea.*

# Investigations in the past

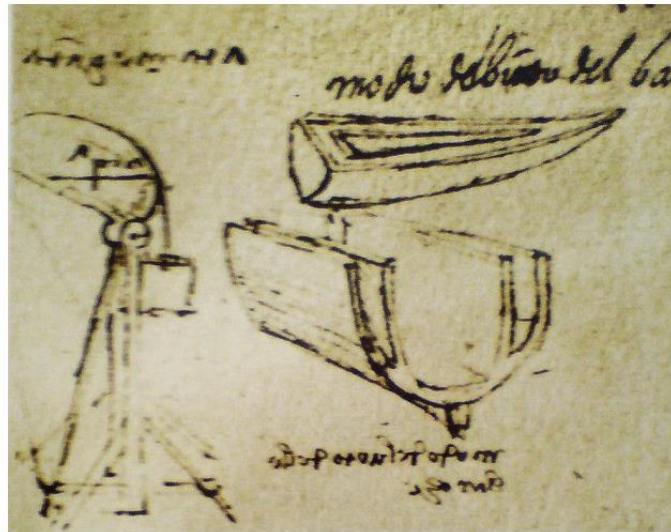

*From O. Ullaland*

A workable solution, with Isobutane, would require a new RICH 1 vessel.  
It must, I think, be a double hull structure.  
It must be designed with simplicity/gas tightness /safety in mind.

On second thought  
- perhaps not.

If you do all that, and in addition manufacture the required new gas system, you have a perfectly safe and leak-tight detector which could work perfectly well with  $C_4F_{10}$  (or similar) without any spillage to the environment.

Inventions and ideas:  
Leonardo da Vinci conceived of the *Double Hull* concept

Perhaps, after all, seen the other volumes, one could let the RICHes work with the gases they have successfully used to work with.

- In the future, the gas tightness of the enclosures will be further improved.
- In such a system, the gas loss is negligible; it may happen only during gas purification.

# Exploring usage of CO<sub>2</sub> in RICH2

RICH2: RUN3

Preliminary

Nominal single photon resolution (in mrad)	MaPMT; CF <sub>4</sub>	MaPMT: CO <sub>2</sub>
Chromatic	0.34	0.53
Overall	0.50	0.66
Yield	34	33

- CO<sub>2</sub> expected to have a worse chromatic error contribution than CF<sub>4</sub>
- Simulation studies expected to be performed to evaluate the effect, from CO<sub>2</sub>.

# Usage of SiPM in the future

- SiPM can reduce the chromatic error and increase the yield. This is expected for LS4.
- We hope that the gains obtained from using SiPMs are not lost with a change of the gas radiator.
- For single photon detection, dark counts are to be kept at the level of 100 kHz/mm<sup>2</sup>
- This requires SiPM to be operated near -100 °C.  
One needs to ensure that radiator gas does not liquefy when using SiPM.  
(The gas radiator is separated from SiPM region by a thin quartz window)

# Non-gaseous radiators in the future

## Aerogel:

- It is planned to test improved versions of aerogel.
- However with  $n \sim 1.03$ , this is for the momentum range below 10 GeV/c.
- This may also require modification of the optics.

## Novel materials:

- R & D starting in designing thin radiators made of photonic crystals (or meta-materials) , with desired  $n$ .
- There are many challenges involved in producing such materials with low chromatic error and high yield.

*Ref: Nature Physics 14, 816-821 (2018).*

# SUMMARY

- Many options for replacing the current radiators with eco-friendly gases were investigated by Olav Ullaland.
- One of those options is to have a pressurized, leak tight container to use isobutane for RICH1.
- His general conclusion was to keep the current gases, unless a fantastic new option comes up in the future.
- In the future we plan to further improve the gas tightness of the gas enclosures.
- Usage of CO<sub>2</sub> in RICH2 is being investigated
- We plan to continue the search for eco-friendly gases which can be used as radiators in the RICH detectors. Any information related to this topic is quite welcome.
- In the future, new photon detectors like SiPM can reduce the chromatic error.
- In parallel , usage of non-gaseous radiators are also being explored
