

Modeling the e-APD SAPHIRA/C-RED ONE camera at a low flux level

Detector Modelling Workshop 2021

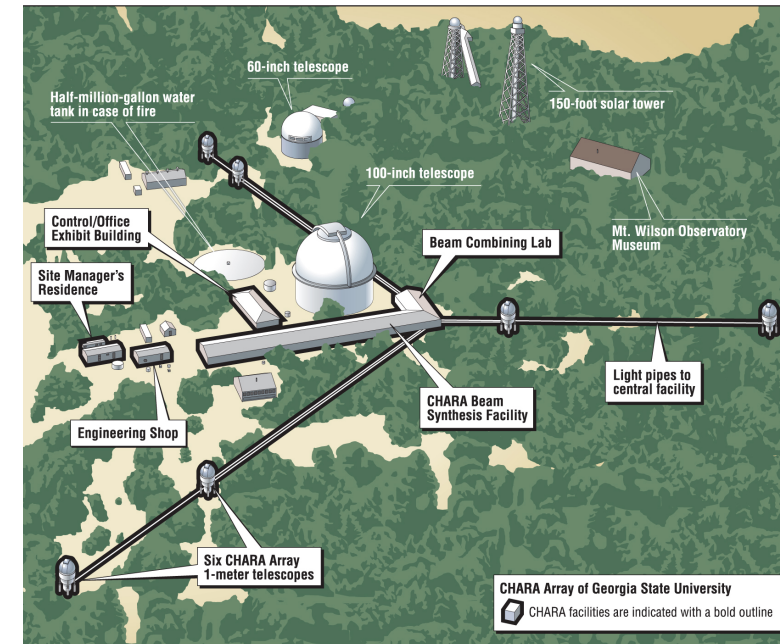

By Cyprien Lanthermann, Narsireddy Anugu, Jean-Baptiste Le Bouquin,
John Monnier, Stefan Kraus, and Karine Perraut

Application: NIR interferometry

- Better angular resolution than direct imaging but sensitivity limitations
- Atmospheric seeing
=> Time scale = 10 ms (H- and K-band)
- Needs:
 - fast (> 200 Hz)
 - sensitive (QE > 50 %)
 - low readout noise (< 1 e⁻/frame/pixel)
 - large format ($> 200 \times 200$ pixel)

=> e-APD is a breakthrough

Electron Avalanche PhotoDiode (e-APD)

Bias voltage in the multiplication region accelerate the electron
 ⇒ Collision ionization
 ⇒ Avalanche effect

Characterized by :

- Mean avalanche Gain
- Excess Noise Factor (ENF)

C-RED ONE camera

- Use a Mark13 SAPHIRA e-APD from Leonardo
- Developed by First Light Imaging (FLI)
- Installed in the MIRC-X instrument (1.1 to 1.9 μm)

Manufacturer characteristics :

- 320 x 256 pixels
- Avalanche gain up to 300
- System Gain : 0.77 ADU/e⁻
- **ENF = 1.25**
- FPS max of 3.5 kHz
- **Dark current < 200 e⁻/pixel/s**
- **Read out noise < 1 e⁻/pixel/read**

- Conclusions

Extracting temporal sequence

- Sub-window of 320 x 20 pixels, 16 reads per frame
 ⇒ Frame rate = 1900 Hz
- Extract temporal sequence of one illuminated pixel
- Subtract median value of several not illuminated pixels of the same line
 ⇒ Take off the sinusoidal parasitic signal

Histograms of count

- No clearly separated peaks => no photon counting ?
- A break between 0 photon events and the others at low flux

Comparison with Poisson distribution

- Introduction
- **Data analysis**
- Modeling
- Results
- Characterization
- Conclusions

$$F (e^-) = \langle ADU \rangle / G_{\text{man}}$$

Poisson distribution for F not consistent with histogram :

Fraction of 0-photon :

- Poisson = 10%

- Data \approx 2.5%

\Rightarrow Total gain is false

Modeling the count distribution

$$Histo(G, F, ENF, adu) =$$

$$\sum_p^{(3)} \left[\overbrace{Poisson(p, F)}^{(2)} \cdot \overbrace{M(ENF, adu/G) * M(ENF, adu/G) * \dots}^{(1) \quad p-1 \text{ convolutions}} \right] * \overbrace{BKG(adu)}^{(4)}$$

1) Distribution of p-photons events:

0 photon => Dirac in 0

1 photon => M

2 photons => M convolved by itself

...

2) Weighting with the corresponding rate of the Poisson distribution, for a given F

3) Addition of the different p-photons distributions

4) Convolution of the result by the Background histogram

Model of gain distribution M

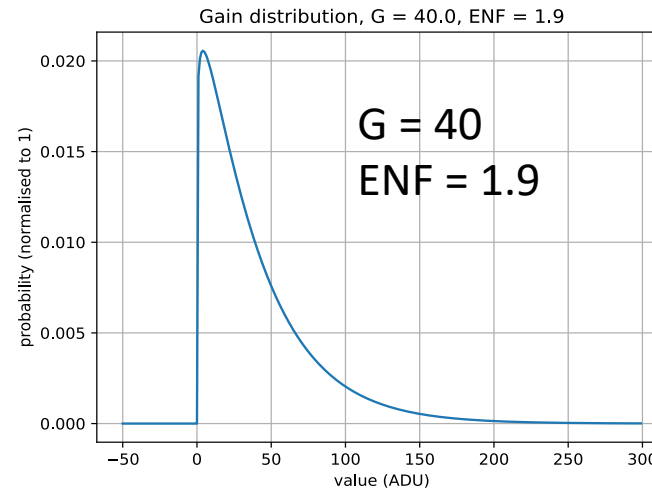

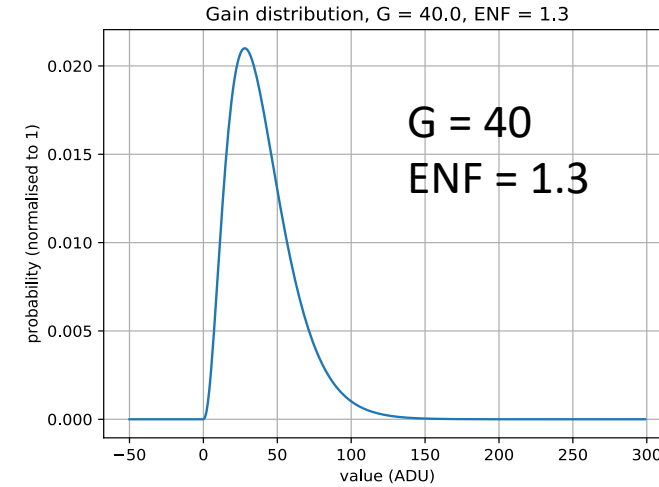

- Introduction
- Data analysis
- **Modeling**
- Results
- Characterization
- Conclusions

Gain distribution (M) :
Defines mean gain (G)
and ENF

$$G = \langle M \rangle$$

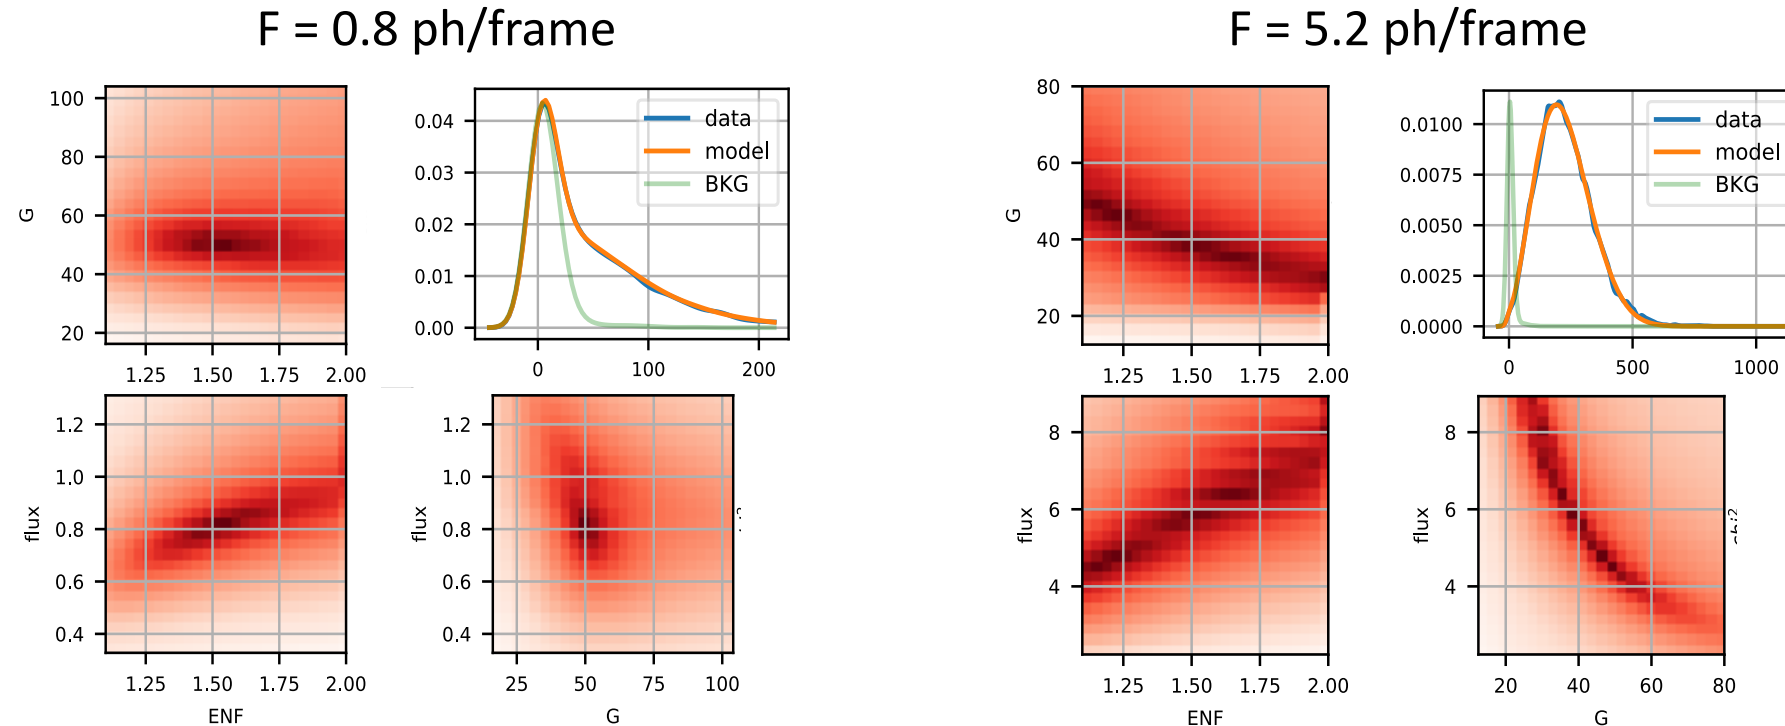

$$ENF = \frac{\langle M^2 \rangle}{\langle M \rangle^2}$$

Gamma distribution

Fitting method

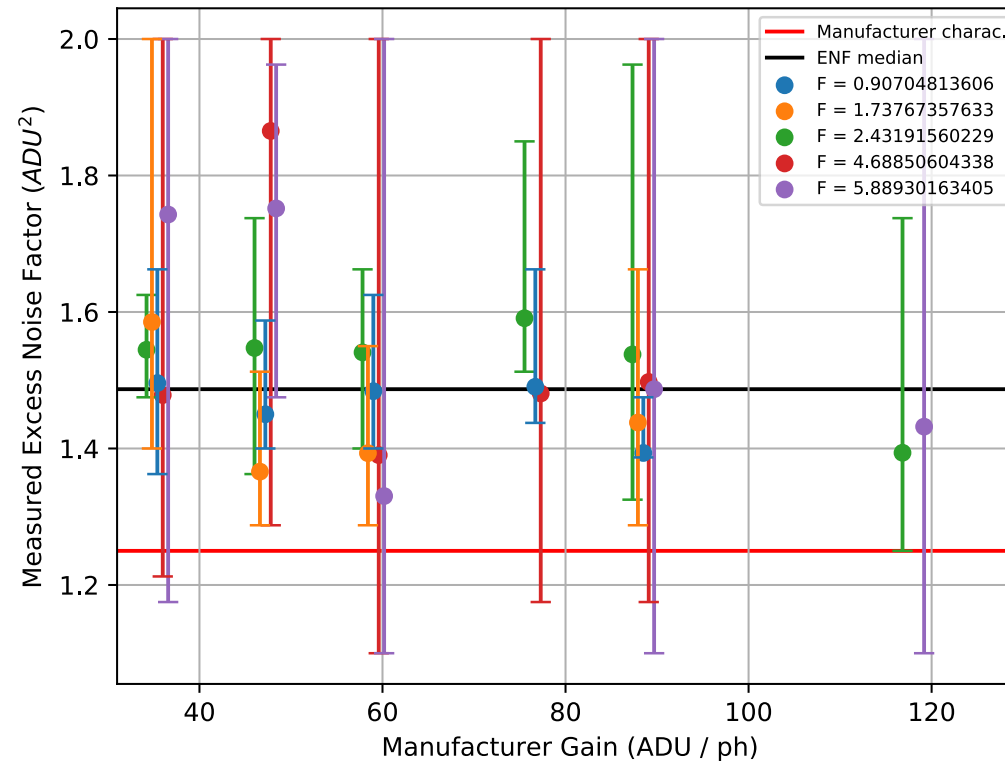

- Introduction
- Data analysis
- **Modeling**
- Results
- Characterization
- Conclusions

- Exploration of the parameter space to perform χ^2 maps
- Best-fit model convincingly reproduces data histogram at all fluxes and gains
- A single solution found in the parameter space at low flux
- Degeneracy of solution at high flux ($F > 3$ e⁻/frame/pixel)

Results

- Introduction
- Data analysis
- Modeling
- **Results**
- Characterization
- Conclusions

Lanthermann et al. 2019

- Results consistent for the same requested gain at different flux
- Some outliers for ENF, but from unconstrained high flux
- $G_{mes} / G_{man} = 0.70 \pm 0.04$
- $ENF = 1.47 \pm 0.03$

Comparison with Poisson distribution

- Introduction
- Data analysis
- Modeling
- **Results**
- Characterization
- Conclusions

New gain
→ New flux
→ New Poisson distribution

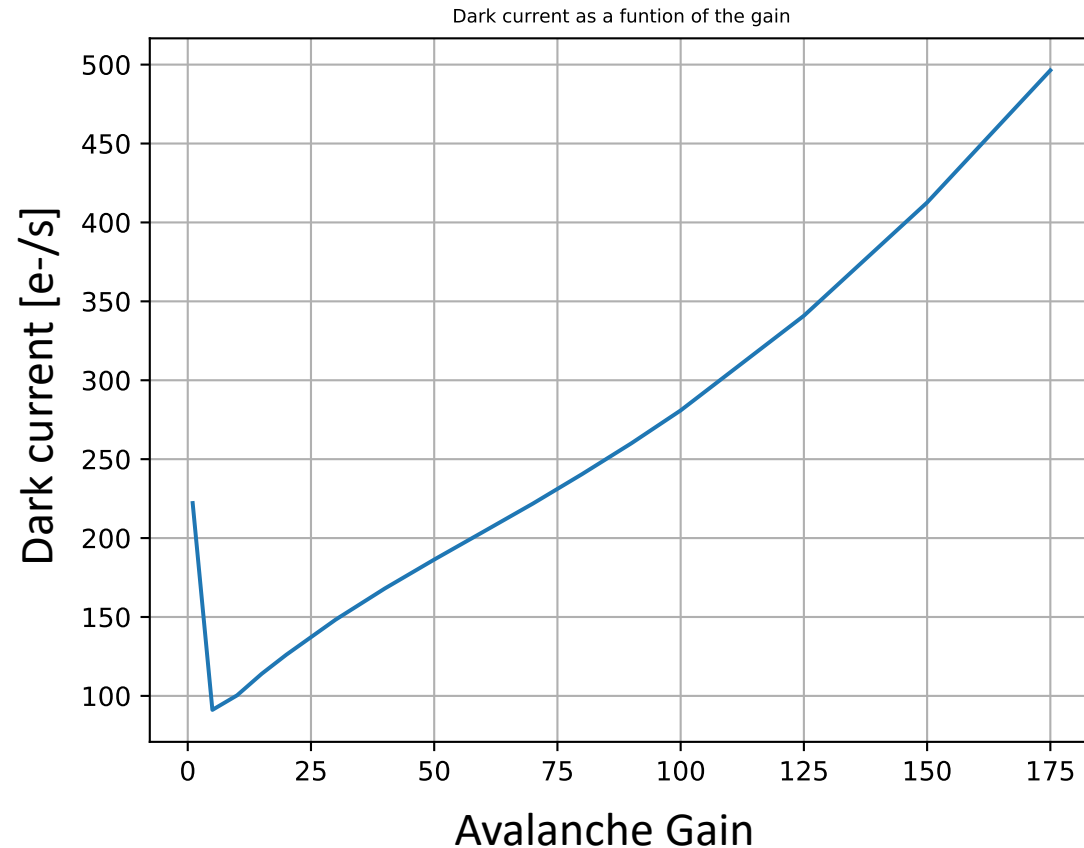

Poisson distribution consistent with histogram

C-RED ONE optimization

Dark current

- Introduction
- Data analysis
- Modeling
- Results
- **Characterization**
- Conclusions

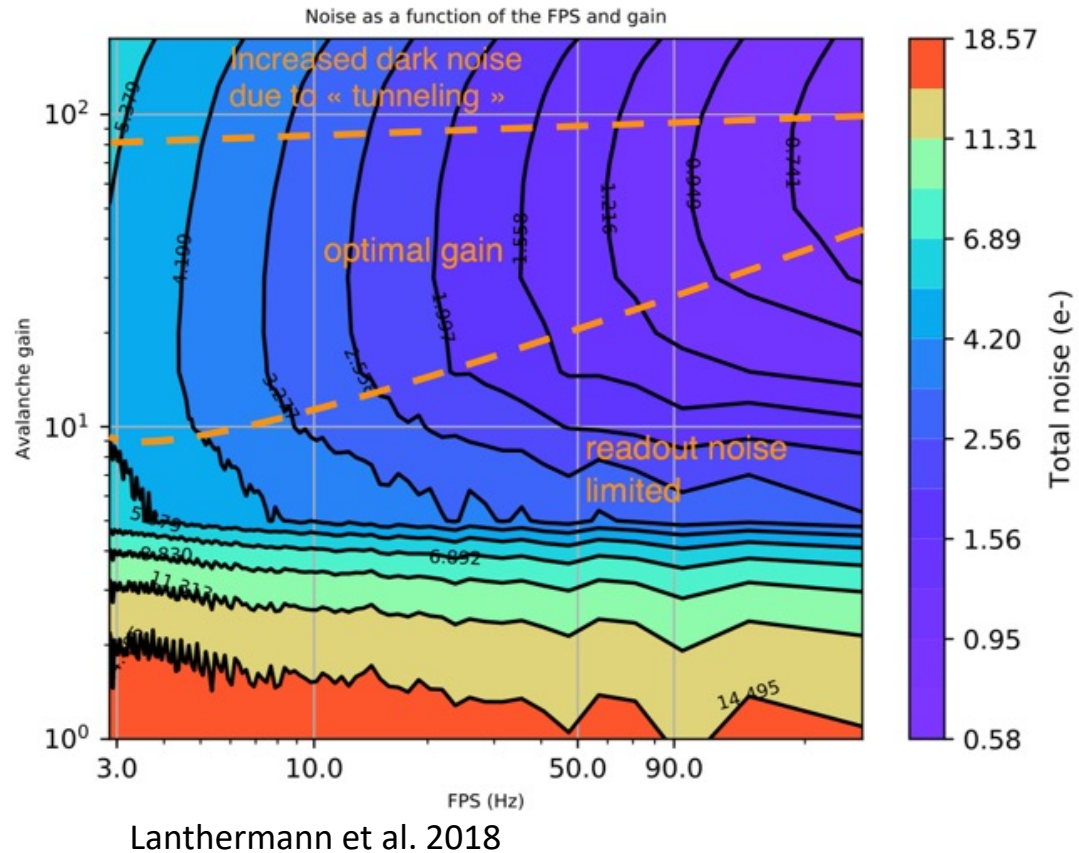

- Minimum dark current = 90 e⁻/s compatible with expected H-band background
- Tunnel effect increasing dark current in e⁻/s with gain

Lanthermann et al. 2018

Noise vs. Frame rate and gain

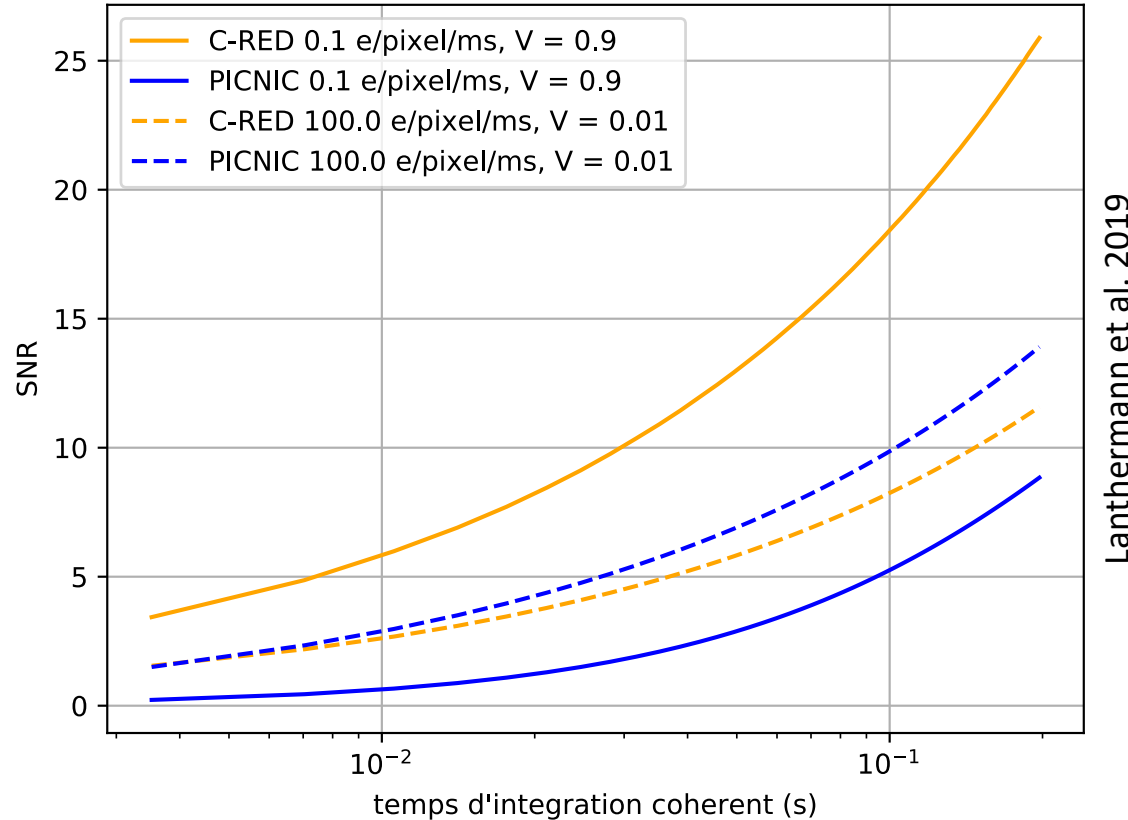

- Introduction
- Data analysis
- Modeling
- Results
- **Characterization**
- Conclusions

- Noise $< 1 \text{ e}^-/\text{frame}/\text{pixel}$ at high frame rate and for avalanche gain between 20 and 175
 - Wide range of gains and frame rates limited by background
- => Recommended avalanche gain = 60

Comparison between MIRC and MIRC-X

- Introduction
- Data analysis
- Modeling
- Results
- **Characterization**
- Conclusions

- Bright targets (stellar surfaces imagery): similar performance with MIRC
- Faint targets (YSOs, Massive stars): 10x less flux required than MIRC

Adapting the Model to K-band: MYSTIC

pixel 1,140, Nreads-Loops 6-6, FPS 1436
 G = 31.422957240034062, ENF = 1.8344108378192487
 F = 0.7717569257482583 ph/pix/frame = 1109.7864592259955 ph/s
 noise = 7.506538663257809, mu = 4.999766540483604

Background flux is high enough already:

- Replaced the background histogram by a gaussian
 - 2 new parameters :
 - sigma: readout noise
 - mu: position of the maximum

⇒ Data well reproduced by the model

⇒ Results consistent throughout different camera's configurations

⇒ Higher ENF value, need to be investigate further

Conclusions

- Proposed model works : total gain and ENF constrained,
 - Advantages : no need of preexisting calibration, typical operational flux
- Spotted a mistake in the manufacturer calibration of the gain
- ENF of 1.47 ± 0.03 compared to the expected 1.25
- Good cosmetic and overall behavior:
 - Reset anomaly
 - 90 Hz parasitic signal
- Real improvement of MIRC-X performances compared to MIRC:
 - Background limited
- K-band model needs further investigation
