GENEVA combines the 3 theoretical tools we use for QCD predictions into a single framework:

1) Fully differential fixed-order calculations

• up to NNLO via *N*-jettiness or q_T -subtraction

2) Higher-logarithmic resummation

up to NNLL' or N3LL via SCET or RadISH

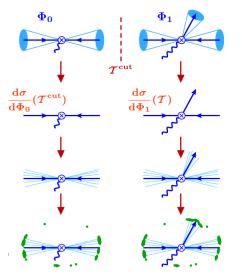

3) Parton showering, hadronization and MPI

 recycling standard SMC. Using PYTHIA8 now, any SMC supporting LHEF and user-hook vetoes is OK

Resulting Monte Carlo event generator has many advantages:

- consistently improves perturbative accuracy away from FO regions
- provides event-by-event systematic estimate of theoretical perturbative uncertainties and correlations
- gives a direct interface to SMC hadronization, MPI modeling and detector simulations.

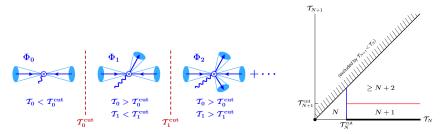

Schematic view of the GENEVA method :

- 1. Choose the resolution parameters, e.g. $\mathcal{T}_0^{\text{cut}}$ or p_T^{cut} , for an IR-finite definition of the events.
- 2. Associate differential cross-sections to events such that events are (N)NLO accurate and the resolution parameter is resummed at high-enough accuracy.
- 3. Shower the events imposing conditions trying to avoid spoiling the resummation accuracy reached at step 2.
- Hadronize, add multi-parton interactions (MPI) and decay without further restrictions.

IR-safe definitions of events beyond LO

At NNLO one needs a 0-jet and a 1-jet resolution parameters. Iterating the procedure, the phase space is sliced into jet-bins

Different choices are possible for the resolution parameters, but one always has:

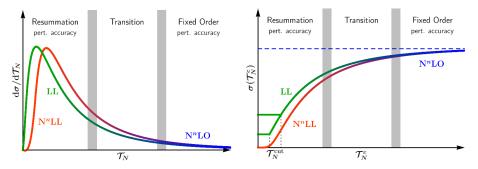

- Emissions below $\mathcal{T}_N^{\text{cut}}$ are unresolved (i.e. integrated over) and the kinematic considered is the one of the event before the extra emission(s).
- Emissions above T_N^{cut} are retained and the kinematics is fully specified.

An *M*-parton event is considered a *N*-jet event, $N \leq M$, fully differential in Φ_N

- Price to pay: power corrections in $\mathcal{T}_N^{\mathrm{cut}}$ due to PS projection.
- Advantage: vanish for IR-safe observables as $\mathcal{T}_N^{\mathrm{cut}} \to 0$

Combining resummation with fixed-order in GENEVA

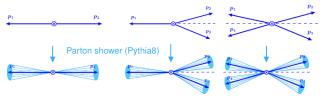

- The inclusion of the higher-order resummation is key to improve the accuracy of the predictions across the whole spectrum.
- > Assuming a counting in which $\alpha_s L \sim 1$, the first "next-to-leading-order" correction to the spectrum enters at NNLL.
- To correctly match this to fixed-predictions one needs to include all singular α²_s terms, hence the NNLL['], and match to NNLO.
- These conditions set the minimum accuracy requirement for GENEVA. If higher-log resummation is available, it can be used.

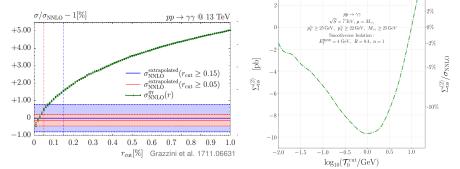

Interfacing to the parton shower and hadronization

Purpose of the parton shower is to fill the 0- and 1-jet exclusive bins with radiation and add more emissions to the inclusive 2-jet bin

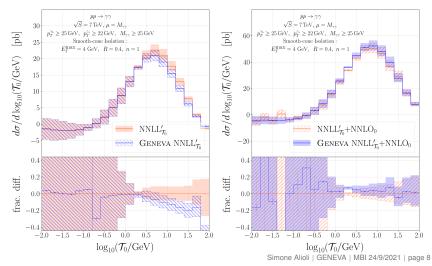

- Ideally it should not change accuracy reached at partonic level.
- ▶ If the shower is ordered in resolution variable, setting SCALUP would be enough.
- ► For different ordering variable, jet-boundaries constraints T^{cut}_k need to be imposed on hardest radiation (largest jet resolution scale)
- Impose the first emission has the largest jet resolution scale, by performing a splitting by hand using a NLL Sudakov and the T_k -preserving map.
- GENEVA is not improving the hadronization stage, which should entirely be taken from the Shower Monte Carlo. However, care must be taken to appropriately re-tune parameters, due to the increased accuracy of perturbative ingredients.
- When MPI evolution is interleaved, the shower restrictions must be applied on the event stripped off by MPI. It can only be done before hadronization, afterwards shower history is mixed up.

- Important background to Higgs boson production and NP searches
- Similar to DY and VH production previously studied, complications from process definition due to QED divergencies
- Requires introduction of photon-isolation procedure, to remove huge background from secondary photons
- Using dynamic-cone (Frixione) isolation in generation. Final analysis can be performed with dynamic or fixed-cone isolation.
- Size of linear power corrections associated to isolation is very challenging, both in q_T and T_0 Ebert, Tackmann 1911.08486, Becher, Neumann 2009.11437

GENEVA for diphoton production

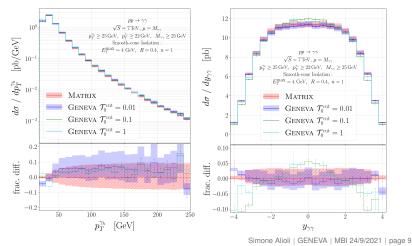

- Introduction of isolation cuts requires particular attention to definition of resummed component.
- Differences arise due to treatment of nonsingular phase-space points which might fail isolation cuts after the projection.

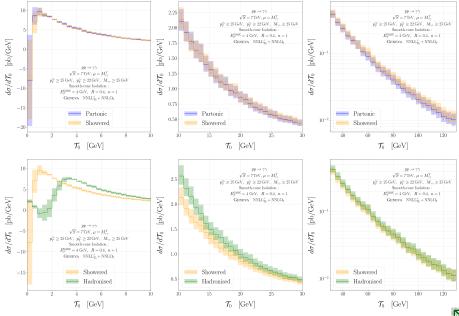

GENEVA for diphoton production

- \blacktriangleright NNLO comparison for 13 TeV LHC, $p_{T,\gamma_h}>25~{\rm GeV}$, $p_{T,\gamma_s}>22$ GeV, Frixione isolation R=0.4
- > Only $q\bar{q}$ -channel included in comparison, gg loop-induced can be added as nonsingular contribution.
- Kinematical-effects at subleading power at order $\mathcal{O}(\alpha_S^2)$ can no longer be neglected.

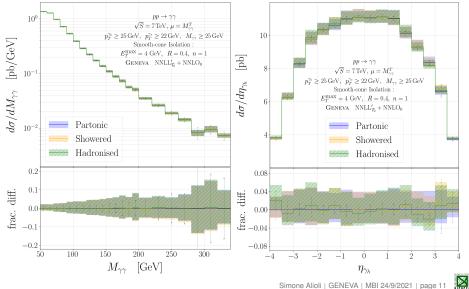

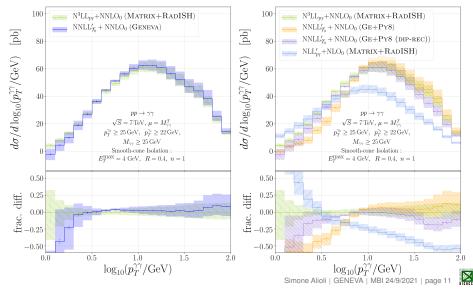

Simone Alioli | GENEVA | MBI 24/9/2021 | page 10

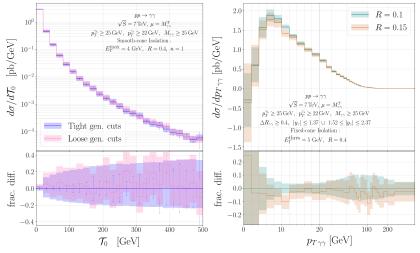

Inclusive quantities not modified, expected changes in exclusive ones.

- Inclusive quantities not modified, expected changes in exclusive ones.
- Shower recoil scheme has large impact in prediction of color singlet pT

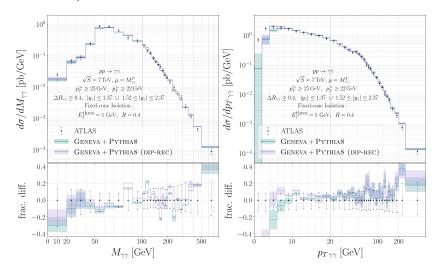

- Inclusive quantities not modified, expected changes in exclusive ones.
- Shower recoil scheme has large impact in prediction of color singlet p_T
- Important to assess independence of final results from generation cuts.

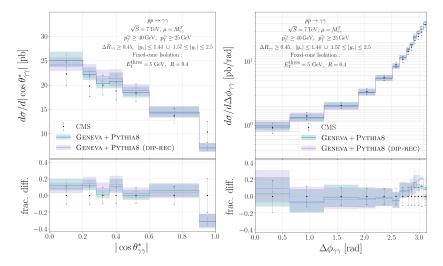

Diphoton: comparison with data

Requires inclusion of gg channel, treated as leading-order contribution and showered by PYTHIA8.

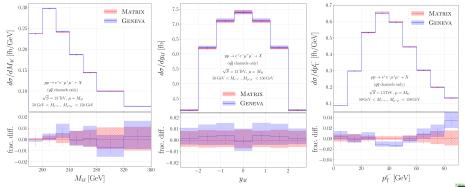

Requires inclusion of gg channel, treated as leading-order contribution and showered by PYTHIA8.

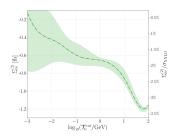

Diboson production: $ZZ \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$

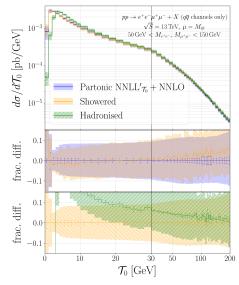

- Experimentally very clean signature.
- Precision needed for costraining anomalous couplings and Higgs boson width.
- Numerically challenging 2-loop corrections taken from VVAMP
- Complex kinematics dependence, validated against MATRIX

Diboson production: $ZZ \rightarrow \ell^+ \ell^- \ell^{\prime+} \ell^{\prime-}$

- Experimentally very clean signature.
- Precision needed for costraining anomalous couplings and Higgs boson width.
- Numerically challenging 2-loop corrections taken from VVAMP
- Complex kinematics dependence, validated against MATRIX
- After showering, expected behaviour for inclusive as well as for exclusive quantities.

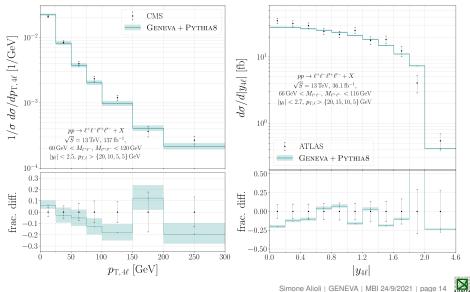

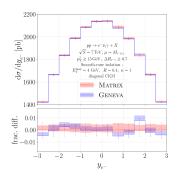

Diboson: comparison with data

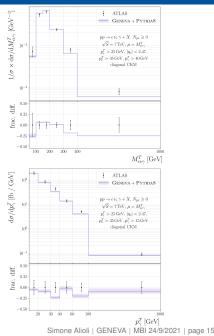

After inclusion of *qq*-channel at LO we compared to ATLAS and CMS

Diboson production: $W\gamma ightarrow \ell u \gamma$

- NLO corrections artificially large due to the presence of a radiation zero at LO
- High sensititivity to non Abelian gauge couplings.
- Can be used to constrain the effects of higher-dimensional operator in the SMEFT
- Complex kinematics dependence, validated against MATRIX

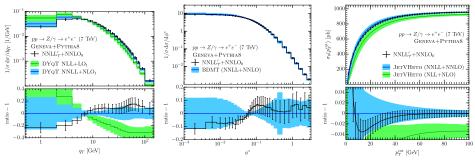

Accuracy for other observables : q_T , ϕ^* and jet-veto

- ► For DY one can compare with dedicated tools DYqT Bozzi et al. 1007.2351 , BDMT Banfi et al. 1205.4760 and JetVHeto Banfi et al. 1308.4634
- Analytic NNLL predictions formally higher log accuracy than GENEVA

- Results are in better agreement with higher-order resummation, despite lack of perturbative ingredients.
- Difficult to formally quantify the accuracy achieved after the parton shower stage, despite starting from a higher-order logarithmic accuracy. Numerical tests are possible, very computationally demanding.
- Recently NLL accurate showers begin to appear. It will be interesting to study how to interface GENEVA to them.
 Dasgupta et al. 2002.11114

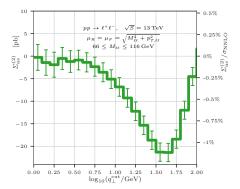

Changing resolution parameter: Drell-Yan using q_T

Using q_T as 0-jet resolution parameter allows for target N3LL_{q_T}+NNLO₀ accuracy

 RadISH performs q_T resummation up to N3LL directly in q_T space

Bizon et al. 1905.05171

- Its internal structure requiring Monte Carlo generation of unphysical events makes it hard to directly link.
- We proceeded building interpolating grids with Chebyshev polynomials and calling these interpolating grids from Geneva.
- Usage of Chebyshev polynomials is key in easily obtaining spectrum from cumulant.

 Results are in good agreement with dedicated RadISH+NNLOJET N3LL+NNLO₀ control runs.

Changing resolution parameter: Drell-Yan using q_T

Using q_T as 0-jet resolution parameter allows for target N3LL $_{q_T}$ +NNLO $_0$ accuracy

- RadISH performs q_T resummation up to N3LL directly in q_T space Bizon et al. 1905.05171
- Its internal structure requiring Monte Carlo generation of unphysical events makes it hard to directly link.
- We proceeded building interpolating grids with Chebyshev polynomials and calling these interpolating grids from Geneva.
- Usage of Chebyshev polynomials is key in easily obtaining spectrum from cumulant.

 Results are in good agreement with dedicated RadISH+NNLOJET N3LL+NNLO₀ control runs.

Changing resolution parameter: Drell-Yan using q_T

- Usage of Chebyshev polynomials is key in easily obtaining spectrum from cumulant.

- Results are in good agreement with dedicated RadISH+NNLOJET N3LL+NNLO₀ control runs.
- ► Shower interface slightly more complicated than T_0 case. N3LL accuracy cannot be achieved formally, but numerically still OK.

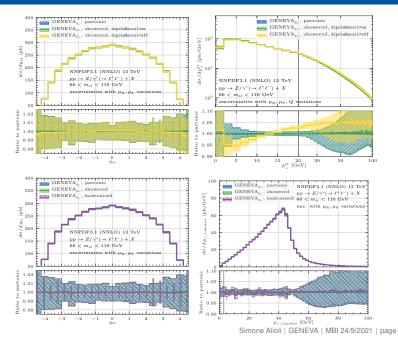

Drell-Yan using q_T : NNLO validation

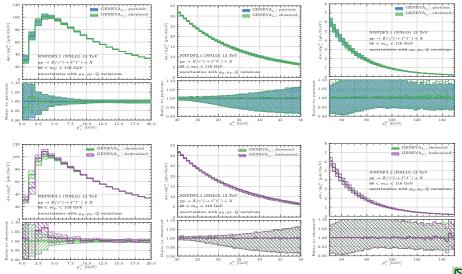

Drell-Yan using q_T : shower and hadronization

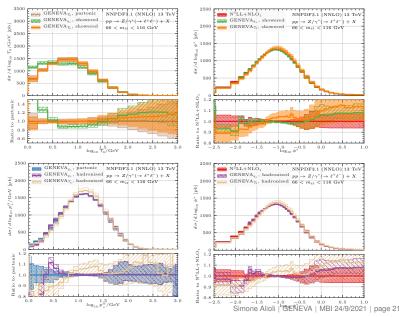

Drell-Yan using q_T : shower and hadronization

 Predictions for transverse momentum almost unchanged from parton-level to final hadronized events.

Drell-Yan comparing GENEVA_{q_T} and $\text{GENEVA}_{\mathcal{T}_0}$

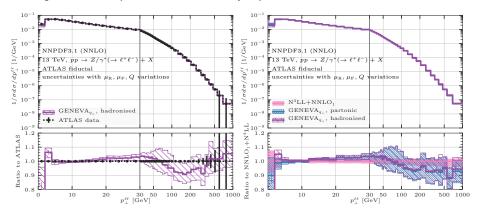

Unique opportunity to study interplay between different higher-order resummations.

Comparison with data

Agreement with precise LHC data vastly improved

- Small differences in transition region due to missing higher-order effects.
- The description of the ϕ^* spectrum shows a similar improvement.

Summary and Outlook

performs matching of NNLO calculations with higher-log resummation and parton showers.

- Higher-order resummation of resolution parameters provides a natural link between NNLO and PS.
- Provides theoretical perturbative uncertainties coming from both fixed-order and resummation on a event-by-event basis.
- Allows for realistic event simulation and interface to detectors.

Current status:

Several processes involving one or more bosons have been implemented

- ▶ $pp \rightarrow V$, $pp \rightarrow VH$, $pp \rightarrow \gamma\gamma$, $pp \rightarrow ZZ$ and $pp \rightarrow W\gamma$
- Others diboson processes in the pipeline, stay tuned..
- Usage of different resolution parameter (q_T) up via RadISH at N3LL now available.

Outlook:

- Extension to more complicated processes.
- Inclusion of EW corrections.
- Investigate formal accuracy of radiation-sensitive observables after showering.

Thank you for your attention!

N-jettiness as jet-resolution variable

N-jettiness is a good resolution parameter. Global physical observable with straightforward definitions for hadronic colliders, in terms of beams q_{a,b} and jet-directions q_j

- N-jettiness has good factorization properties, IR safe and resummable at all orders. Resummation known at NNLL for any N in SCET [Stewart et al. 1004.2489,
- $\mathcal{T}_N \to 0$ for N pencil-like jets, $\mathcal{T}_N \gg 0$ spherical limit.
- $T_N < T_N^{\text{cut}}$ limits the activity outside the jets

1102.4344]

More details about the interface to PYTHIA8.

Each event multiplicity is treated differently:

 Φ_0 events below $\mathcal{T}_0^{\text{cut}}$ ($\mathcal{O}(1\%)$ of total xsec)

- > All events have $T_0 = 0$. Here the shower should restore the emissions which were integrated over. Only constrain is on normalization, shape entirely given by PYTHIA.
- Events are showered starting from SCALUP $\sim \sqrt{QT_0^{\text{cut}}}$ and re-showered until $T_0^{PY} < T_0^{\text{cut}}$. Small 5% spillover allowed to avoid hard border.

 Φ_1 events made negligible by splitting down to $\Lambda_1 \lesssim 100$ MeV ($\mathcal{O}(0.1\%)$ of total xsec)

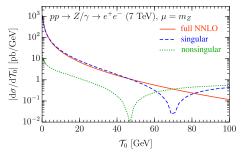

- Events have a non-zero value of T_0 while $T_1 = 0$.
- ► Showered starting from SCALUP $k_{T,max} \sim \sqrt{QT_1^{\text{cut}}}$ and re-showered until $T_1^{PY} < T_1^{\text{cut}}$.

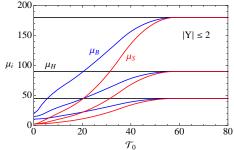

Φ_2 events ($\mathcal{O}(99\%)$) of total xsec)

- Bulk of events, with nonzero values of T₀ and T₁
- Starting scale set to $k_{T,2nd} \sim \sqrt{QT_1}$, re-shower events until $T_2^{PY} < T_1$
- ▶ PYTHIA first emission can be shown to shift T_0 distribution starting from order α_s^3/T_0 on average (term beyond NNLL')

Scale profiles and theoretical uncertainties

- Theoretical uncertainties in resum. are evaluated by independently varying each µ.
- ▶ Range of variations is tuned to turn off the resummation before the nonsingular dominates and to respect SCET scaling $\mu_H \gtrsim \mu_B \gtrsim \mu_S$
- FO unc. are usual $\{2\mu_H, \mu_H/2\}$ variations.
- Final results added in quadrature.

$$\mu_H = \mu_{\rm FO} = M_{\ell^+\ell^-} ,$$

$$\mu_S(\mathcal{T}_0) = \mu_{\rm FO} f_{\rm run}(\mathcal{T}_0/Q) ,$$

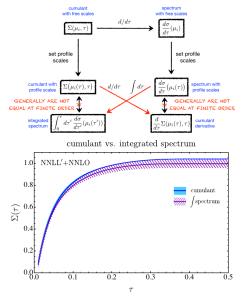

$$\mu_B(\mathcal{T}_0) = \mu_{\rm FO} \sqrt{f_{\rm run}(\mathcal{T}_0/Q)}$$

▶ $f_{run}(x)$ common profile function: strict canonical scaling $x \to 0$ and switches off resummation $x \sim 1$

Scale profiles that preserve the total cross-section

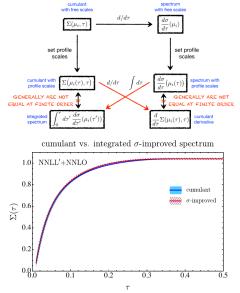

- Different advantages in resumming the cumulant (better cross-section and correlated unc.) or the spectrum (better profiles in trans and tail region and better point-by-point unc.)
- The two approaches only agree at all order. Numerical differences when truncating are a problem for NNLO precision.
- Enforcing equivalence by taking derivative or integrating results in unreliable uncertainties.
- Similar problem in preserving total xsec in matched QCD resummation solved with ad-hoc smoother.
- We add higher-order term to the spectrum such that the total NNLO XS is preserved.
- Correlations now enforced by hand for up/down scales

Scale profiles that preserve the total cross-section

- Different advantages in resumming the cumulant (better cross-section and correlated unc.) or the spectrum (better profiles in trans and tail region and better point-by-point unc.)
- The two approaches only agree at all order. Numerical differences when truncating are a problem for NNLO precision.
- Enforcing equivalence by taking derivative or integrating results in unreliable uncertainties.
- Similar problem in preserving total xsec in matched QCD resummation solved with ad-hoc smoother.
- We add higher-order term to the spectrum such that the total NNLO XS is preserved.
- Correlations now enforced by hand for up/down scales

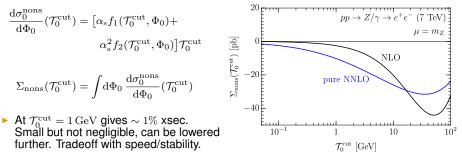

NNLO accuracy in GENEVA: nonsingular rescaling

Resum. expanded result in $d\sigma_{>1}^{nons}/d\Phi_1$ acts as a differential NNLO T_0 -subtraction

$$\frac{\mathrm{d}\sigma_{\geq 1}^{\mathrm{NLO}_{1}}}{\mathrm{d}\Phi_{1}} - \left[\frac{\mathrm{d}\sigma^{\mathrm{NNLL'}}}{\mathrm{d}\Phi_{0}\mathrm{d}\mathcal{T}_{0}}\,\mathcal{P}(\Phi_{1})\right]_{\mathrm{NLO}_{1}}$$

- Nonlocal cancellation in Φ_1 , after averaging over $d\Phi_1/d\Phi_0 d\mathcal{T}_0$ gives finite result.
- To be local in \mathcal{T}_0 has to reproduce the right singular \mathcal{T}_0 -dependence when projected onto $d\mathcal{T}_0 d\Phi_0$.

- ► $f_1(\Phi_0, \mathcal{T}_0^{\text{cut}})$ included exactly by doing NLO₀ on-the-fly.
- For pure NNLO₀, we currently neglect the Φ_0 dependence below $\mathcal{T}_0^{\text{cut}}$ and include total integral via simple rescaling of $d\sigma_0^{\text{MC}}/d\Phi_0(\mathcal{T}_0^{\text{cut}})$.
