The EDRO board connected to the Associative Memory: a “Baby” FastTracKer processor for the ATLAS experiment

Data selection at hadron colliders

Search for rare SM or predicted BSM processes push the collider's intensity to new frontiers

Rare processes are overwhelmed by well-known processes
  · 8-9 orders of magnitude between Higgs and total cross-section
  · Need to prioritize the physics output and leave flexibility for the unexpected

Need sophisticated techniques to maximize the bandwidth for interesting events
Online Tracking @ L2

Charged particle trajectories provide very powerful information for sophisticated trigger selection.

SVT processor at L2 was a key element for many analyses in the CDF experiment. FTK is the “new generation” SVT for ATLAS.

Track-based algorithms (b-tagging, lepton isolation, taus) have an advantage over calo-based algorithms in crowded events with many pile-up interactions.

LHC @10^{34} cm^{-2}s^{-1} → 25 pile-up events
LHC @3 \times 10^{34} cm^{-2}s^{-1} → 75 pile-up events → FTK target

all charged particles with $|\eta| < 2.5$

reconstructed tracks with $p_t > 2.0$ GeV
An associative memory (AM) chip allows a full parallel search in the pattern bank.

Similar to commercial CAMs + extended functionalities.

In FTK, tracking is divided into two separate steps

- The pattern matching uses a large bank of patterns and special hardware (associative memory - AM)

- The track’s parameters are evaluated using a linear Principal Component Analysis algorithm (DSP MACC units in FPGA)

\[ p_i = \sum C_{ij} \cdot x_j + q_i \]
FTK Architecture

Complex system, many units:

- **48** Data Formatters (DF)
  - Clustering Mezzanine

- **128** Processing Units
  - AUX Board (FPGA):
    - Data Organizer (DO)
    - Track Fitter (TF - 8 layers)
    - Hit Warrior (HW)
  - AM Board with ~10M patterns on AMchip04 custom CAMs

- **32** Final Boards (FPGA)
  - Final Fit (11 layers)
  - Final Hit Warrior

FTK will reconstruct tracks in all Inner Detector regions

~100 μs latency

EDRO+AM(+GF) “baby FTK”

Data from a small projective slice of silicon detector.

**Dual Port HOLA** (silicon detector front-end)
Flow Control (XON/XOFF) on second port disabled → parasitic with respect to the ATLAS data flow.

Start early development of **software** and **firmware** on existing boards and prototypes.

EDRO Board with clustering mezzanine + AMBSLIM (+ GigaFitter)

This setup is also the **environment for testing** future prototypes and production boards.
EDRO+AM basic setup

EDRO Hit generator:
- Straight tracks + noise
- Loop over preloaded hits

Internal Hit gen

EDRO

AMBoard

PC (storage)
For monitoring & debugging

s-link

Simple Test Setup: the EDRO board internally generates simple events, the AMBoard finds known patterns and sends the information back to the EDRO board.

The EDRO board can trigger on hit multiplicity or AM roads:
- Test EDRO ↔ AM connection and stability
- Test AM vs AMsim over many events
FTK Stage 1 Setup: hits from PC simulation or real front-end are received by the Clustering mezzanine. Clustered hits are sent by the EDRO board to the AMBoard, the AMBoard finds patterns (roads) and sends them back to the EDRO.

- **Pattern bank efficiency** studies
- **Algorithm studies** → lepton isolation in a small projective tower
EDRO Board

General purpose DAQ board:

- **S-Link** connection to DAQ PCs

- **Two mezzanine slots** for inputs from front-end. *FTK clustering mezzanine* is compatible with this slot.

- **Large FPGA** (Stratix II) for local computation

- EDRO to EDRO connection to build complex DAQ systems (not used in this application)

- Backplane direct connection to AM Board

Used for data acquisition in:

- **ATLAS Lucid**
- **SLIM5** (silicon detectors r&d project)
Clustering Mezzanine

- Features
  - Receives up to 4 S-Link inputs
  - 2D clustering for pixels
    - Allows to correct with Time over Threshold information (TBC)
  - 1D association of contiguous SCT clusters from ABCD
  - Sustains input data rate of 40MHz S-Link words
  - Sends clusterized data out over 1 or more channels to mainboard (EDRO, DF)

First prototype just arrived (May 2011). Connection to EDRO tested.

Conceptual 2D pixel clustering firmware developed. Porting to mezzanine FPGAs ongoing.
New generation AM Board developed for SLIM5 and FTK:

- supports 4x CDF LAMB mezzanines (each up to 32 AMchip03) for a maximum capacity of 640k patterns (320k using CDF's single-sided LAMBs)

- 6 input buses
- 1 output bus (roads)
- 6 output buses (hits, for pipelined AMBoards)

- Backplane connection to EDRO Board

Hits from EDRO
Roads from AM pipeline to EDRO
First tests in INFN Bologna

Events with 1-5 internally generated patterns+noise per event were sent @40MHz to the AMBoard to test board's connection, firmware and control software.

- EDRO+AM Basic Setup has been tested in INFN Bologna
- Generated hits
- Straight tracks in a telescope-like configuration.
- Plot hit position on 4 planes
- Pattern bank was generated including only tracks on the diagonal.
- AM trigger selects only those tracks

Hardware & Software integration
RoadMap to data taking in 2012

• Complete crate installation and debug (EDRO+Clustering mezzanine+AMBoard)

• Move EDRO+AM crate to a test stand at CERN by end of 2011

• Install dual port HOLAs in silicon detector RODs

• Start parasitic data taking and study in 2012
  • Add track fitting functionality using CDF GigaFitter board
  • When more prototypes are ready (ie. AMBoard with 8 input buses and AMchip04) add them to the test stand
Conclusions

• Tracking is an important tool for effective online data selection at hadron colliders

• FTK is a complex hardware processor to enable full track reconstruction with offline quality in the ATLAS Level 2 trigger

• EDRO+AM crate with all FTK functions for early testing of the algorithm and first prototypes in the ATLAS environment
  • It will reconstruct tracks in a small projective slice of the detector
  • It will use existing prototype boards from past experiments and R&D efforts
  • Our goal is to take real data (in parasitic mode) by 2012 and test with the acquired data the real efficiency of some of our track-based algorithms (lepton isolation)
Backup
Dual HOLA (UChicago)

Developed by University of Chicago

Backward compatible with old HOLA

Two outputs with flow control XON/XOFF

Possibility to disable flow control on each outputs

One output to normal silicon detectors RODs, no need to change anything in the rest of infrastructure.

One output to FTK. With flow control disabled we could be parasitic during installation/developing. After the system is fully installed and commissioned easy integration with ATLAS TDAQ just enabling flow control.
GigaFitter

Mezzanine for Pulsar Board (CDF/Magic experiments) with a powerful Virtex-5 FPGA.

Used in SVT (CDF) for the linear fit of all 12 phi slices in parallel

The Pulsar Board has S-Link connection and can receive Hits+Roads from the EDRO Board and perform the second stage of the FTK algorithm: linear fit of the track parameters
EDRO+AM+GF setup

Complete FTK-like Setup:
All functionalities of FTK are implemented, the EDRO send hits+roads to the GigaFitter for the 2\textsuperscript{nd} stage of the FTK algorithm.
Why L1-L2 early TRACKING is IMPORTANT?

The most **STANDARD STIFF LEPTON TRIGGERS** based on **ISOLATION** have problems at very high pile-up.

The calorimeter tower integrates energy from **all the particles**, also from **Pileup**!

We want **ISOLATION** from **HARD SCATTERING** not from **Pileup**!

**Lepton identification**: primary vertices fast identification → Isolation with tracks of $P_T > T_h$ and from right vertex

**Only 7 vertices**: imagine 100!

Tracking more stable than **calorimetric isolation against pile-up**!
**Why FTK is IMPORTANT? Stiff Muon isolation**

- **EM calorimeter isolation:** energy above 60 MeV in 0.07 < ΔR < 0.4

- **Tracking isolation:** μ PT/(PT sum tracks in ΔR<0.2)

- **Isolation based on Tracks from primary vertex** (Track_z<10 mm From μ_z)

- **FTK tracks**

- **Efficiency** from 20% to 80%

- **Luminosity increase!**

- Cuts set so that rejection factor for bb events is 10.

- **EM isolation only** 60 and 120 MeV THs

- **Pythia W→μν**

- **Pythia W→μν**

- **Pythia bb** μPt>15 GeV

- **Pythia bb** μPt>15 GeV

- **Pythia bb** μPt>15 GeV

- **Pythia bb** μPt>15 GeV

- **Pythia bb** μPt>15 GeV

- **Pythia bb** μPt>15 GeV
Why Online Tracking is IMPORTANT? Hadronic Taus

leading $P_T$ track in $R_i$ ($R_i=0.35$ around jet axis)

$P_T > 6$ GeV

$R_{sig} = 0.13$ & $R_{iso}=0.26$ around leading track;

1 (1-prong) or 2-3 (3-prong) tracks in $R_{sig}$;
no tracks with $P_T$ above 1.5 GeV in $R_{iso}$. 
Efficiency on Jets: FAKES for Had Tau selection

1-prong
