

2021 Meeting of the Division of Particles and Fields of the American Physical Society (DPF21)

Monday, 12 July 2021 - Wednesday, 14 July 2021

Zoom

Book of Abstracts

Contents

Progress on construction and qualification tests of the Mu2e electromagnetic calorimeter mechanical structures	1
THE ITALIAN SUMMER STUDENTS PROGRAM AT THE FERMI NATIONAL ACCELERATOR LABORATORY	1
The Light Dark Matter eXperiment, LDMX	2
The Higgs and Leptophobic Force at the LHC	3
Ultra-High-Energy Tau Neutrino Cross Sections with GRAND and POEMMA	3
CP-Violating Neutrino Non-Standard Interactions in Long-Baseline-Accelerator Data	3
Color-octet scalars in Dirac gaugino models with broken R symmetry	4
Picosecond Timing Layers for Future Calorimeters: Updates from the Askaryan Calorimeter Experiment (ACE)	4
Confronting muon $g-2$ in SUSY GUTs with LHC-Run3 and Dark Matter Experiments	5
Nanosecond machine learning with BDT for high energy physics	5
Experimental signatures of a new dark matter WIMP	6
Higgs to charm quarks in vector boson fusion plus a photon	6
Quark and Gluon Contents of a Lepton at High Energies	7
Viable Full Unification of the Standard Model into E_8	7
Strong constraints on thermal relic dark matter from Fermi-LAT observations of the Galactic Center	7
A Supersymmetric Flavor Clockwork	8
Extending QED to Interactions of the Full Eight-Component Vacuum Wavefunction of the Geometric Representation of Clifford Algebra	8
Searching for Cosmic Strings using data from the third Advanced LIGO-Virgo observing run	9
New signatures of decaying HNLs in large scale detectors	9
Welcome	10

THz Photon Source Testing for the BREAD Experiment	10
The REDTOP experiment: An eta/eta' factory to explore Physics Beyond the Standard Model	11
New bounds on sneutrino masses through collider searches	11
Slow control and data acquisition software interfaces in the Mu2e experiment	12
DUNE The Deep Underground Neutrino Experiment	12
ProtoDUNE Physics and Results	13
The DUNE Near Detector	13
NLO Merging using HJets	14
Performance portability of random number generation in SYCL	14
Progress toward building a pair of scintillating bubble chambers for WIMPs and reactor CEvNS	15
Performance of Enhanced Wavelength-shifting Fibers for the Mu2e Cosmic Ray Veto Detector	15
Fabrication of a high efficiency cosmic ray veto detector for the Mu2e experiment.	16
NNLO single-top-quark production and decay: Discrepancies resolved, PDFs challenged	16
A Novel Approach to Unsupervised Learning for Anomalous Jet Identification with a Variational Recurrent Neural Network	17
Testing freeze-in with Z bosons	17
QED radiative corrections to charged-current neutrino-nucleon elastic scattering for accelerator neutrino experiments	18
Search for Vector-Like-Quarks T/B in Same-Sign Dilepton and Multi-lepton Final States at $\sqrt{s} = 13$ TeV	18
Search for top squarks in final states with two top quarks and several light-flavor jets in proton-proton collisions at $\sqrt{s} = 13$ TeV	19
Search for vector boson scattering production of VW pairs in the semi-leptonic channel at CMS	19
Additional Baryons and Mesons	20
Search for new particles in events with energetic jets and large missing transverse momentum in proton-proton collisions at $\sqrt{s} = 13$ TeV	20
Explicit Soft Supersymmetry Breaking in the Heterotic M-Theory B-L MSSM	21
The R-parity Violating Decays of Charginos and Neutralinos in the B-L MSSM	21
Cosmological Simulations of Axion String Radiation	22
First Results of the AICap Experiment	22

Diamond detector for dark matter direct detection	23
Jet Energy Scale and Resolution Measurements at CMS	23
New beam test results of 3D detectors constructed with poly-crystalline CVD diamond	24
Latest Results on the Radiation Tolerance of Diamond Detectors	24
QED Model of Massless Neutrino Oscillation in the Geometric Representation of Clifford Algebra	25
RADiCAL - Innovative Ultracompact Radiation-hard, Fast-timing EM Calorimetry	25
Unfolding ATLAS Collider Data with the Novel OmniFold Procedure	27
On a rigorous Framework for a Quantum N-Body Theory on curved Spacetime	27
Searches for long-lived particles with the CMS experiment	28
Recent Progress in ML for Tracker DQM	28
Model Validation and Extraction of the Inclusive Muon Neutrino Charged Current Cross Section at MicroBooNE	28
Application of Quantum Machine Learning using the Quantum Kernel Algorithm on High Energy Physics Analysis at the LHC	29
Track-Based Triggers for Long-Lived Particles at Future Colliders	29
Measurements of the top quark pair production in 5.02 TeV pp and PbPb collisions	30
Toponium Phenomenology at the LHC	30
Development of a System for Beam Abort and Luminosity Determination at the HL-LHC based on polycrystalline CVD diamond	31
Higgs Physics at FCC-ee	32
Search for Light Pseudoscalar Boson in the Composite Higgs Model using the CMS Detector	32
Machine Learning for Background Hit Rejection in the Mu2e Straw Tracker	32
Dark Energy Spectroscopic Instrument: Science Overview	33
ECAL trigger primitives performance in Run 2 and improvements for Run 3	33
Variable Importance Ranking in the CMS Search for pp to ttt in the Single Lepton Final State at a Center-of-Mass Energy of 13 TeV	34
The Earth as a transducer for dark-photon dark-matter detection	34
TeV-scale Lepton Number Violation: $0\nu\beta\beta$ -decay, the origin of matter and energy frontier probes	35
Photons after muon capture on aluminum and titanium	35
Warming Up Cold Inflation	36

Unfolding at the LHC: A review of unfolding at the LHC, including recent and future developments with RooUnfold.	36
Collider and GW complementarity in the 2HDM	37
Magnetic charge and Massive Photon	37
Self-interacting Dark Matter with Scalar Dilepton Mediator	38
Flavor changing top decays to charm and Higgs with $\tau\tau$ at the LHC	38
A tri-muon trigger for pair-production of dark photons with the CMS Experiment at the HL-LHC	39
Possible Structural Linkage between Neutrinos and Charged Leptons in Neutrinos' Own Maximum Contact	40
Space-Time Conjunction	40
Measurement of the properties of Higgs boson production at $\sqrt{s} = 13$ TeV in the diphoton decay channel using 139 fb^{-1} of pp collision data with the ATLAS experiment	41
Search for resonant pair production of Higgs bosons in the bbbb final state using 139 fb^{-1} of $\sqrt{s} = 13$ TeV pp collision data with the ATLAS detector	41
Improvements to ATLAS Inner Detector Track reconstruction for LHC Run-3	42
Framework for Hyperparameter Optimization in Machine Learning using the ATLAS Grid Computing Resource	42
Drell-Yan angular lepton distributions at small x from TMD factorization	43
Reconstructing silicon pixel hits using neural networks	43
Search for the Higgs boson decaying to a pair of muons in pp collisions at 13 TeV with the ATLAS detector	44
Electroweak Restoration at the LHC and Beyond	44
The calculation of inelastic neutrino-nucleus scattering	45
An intelligent Data Delivery Service (iDDS) for and beyond the ATLAS experiment	45
Dark Energy Spectroscopic Instrument: Instrumentation Overview	46
Exploring color-octet scalar parameter space in minimal R-symmetric models	46
SM Extension with Anomaly Free Flavor U(1)	47
Calibration of the light flavour mistag rate for ATLAS b -jet identification algorithms using the negative tag method in pp collisions at $\sqrt{s} = 13$ TeV	47
Search for non-resonant di-Higgs production in the $HH \rightarrow b\bar{b}\gamma\gamma$ decay channel in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector	48
Missing transverse momentum algorithm improvements for the ATLAS High Level Trigger for Run 3 for pp collisions	48

Electroweak Symmetry Non-restoration in UV-complete Models with New Fermions . . .	49
Normalization of the Mu2e Charged Lepton Flavor Violation Experiment	49
A real time sub-picosecond phase correction system.	50
Measuring Neutrino-Nucleon Cross-Sections with FASERnu	50
Neural Empirical Bayes: Source Distribution Estimation and its Applications to Simulation- Based Inference	51
Constraints on Axions from Cosmic Distance Measurements	51
Explainable AI for ML jet taggers using expert variables and layerwise relevance propaga- tion	52
Searches for new resonances decaying to at least one top quark in pp collisions at a center- of-mass energy of 13 TeV.	53
FASER Commissioning	53
Analysis Optimization of the VBF HWW Measurement at the ATLAS Experiment	54
Transformer Networks for NOvA Event Classification	54
Massive Neutrinos and Dark Sector Cosmology from the High-Redshift Cosmic Web . . .	54
Progress towards a more sensitive CWoLa hunt with the ATLAS detector	55
Measurement of the CP -violating phase ϕ_S in $B_S^0 \rightarrow J/\psi\phi$ decays in ATLAS at 13 TeV	55
Calibration of q/g Taggers in the ATLAS Detector	56
Probing Extremely Weakly-Interacting Particles in Gamma Factory	56
Search for a Generic Heavy Higgs Boson at ATLAS	57
The Integration and Commissioning of the Small-Strip Thin Gap Chambers for ATLAS New Small Wheel Phase-I Upgrade	58
Active Learning for Exclusion level set estimation with the ATLAS experiment	58
Some reflexions on hidden features of SM extensions with scalar triplets	59
Probing the minimal U(1) model at future lepton colliders via the fermion pair-production channel	59
Dark matter and neutrino mass in the radiative seesaw model	60
A genuine fermionic quintuplet seesaw model: phenomenological introduction	60
Testing the neutrino mass generation mechanism at the colliders	61
Search for Rare Higgs Decays into Z Bosons and J/Psi Mesons or into Quarkonium Pairs with the CMS Experiment	61
W + W - H production through bottom quarks fusion at hadron colliders	62

ETROC project for the CMS MTD Endcap Timing Layer (ETL)	62
A simple solution to the LSND, MiniBooNE and muon g-2 anomalies	63
Search for Dark Matter with 2HDM+pseudoscalar model with the ATLAS detector	63
Effective Field Theory interpretation of the VBF HWW differential analysis with the ATLAS detector	64
Search for four top quark production in the single-lepton final state with the CMS data	64
Radiation Modeling and Shielding Design for the Mu2e Branching Ratio Normalization Detectors	65
Measurement of the Z boson production in association with at least two b jets in pp collisions at $\sqrt{s} = 13$ TeV	66
CaloFlow: Fast and Accurate Generation of Calorimeter Showers with Normalizing Flows	66
Search for dark matter in events with missing transverse momentum and a Higgs boson decaying to a photon pair in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector	67
Electrical and functional performance of the first full loaded ITk Strip stave at Brookhaven National Laboratory	67
Reconciling a minimal length scale with lack of photon dispersion	68
Developing a Highly Successful Planetarium Show on Dark Matter	68
Beyond the Standard Model Effective Field Theory: The Singlet Extended Standard Model and Higgs Flts	69
Search for Dark Matter from Baryon Number Violation Process in Proton-Proton Collisions at $\sqrt{s} = 13$ TeV.	69
Particle Physics Course-based Research Experience During Remote-Learning	70
First Order Electroweak Phase Transition from Weakly Coupled sub-GeV Physics	70
Baryons and Dark Matter from Dark Phase Transitions	71
Cosmic Ray Event Reconstruction in Mu2e	71
NLO EW corrections to $W^+Z\gamma$ production in SM and tree-level effects of dimension-eight operators in SMEFT at the LHC	72
Implications of the Muon Anomalous Magnetic Moment for 3-3-1 Models	72
Search for Charged Higgs decaying into a top and bottom quark with a single leptonic final state	73
Machine Learning the Higgs-top CP Measurement	73
The ATLAS Multi-threaded Trigger Selection Framework	73
Installation and commissioning status of the new GEM muon detectors in the CMS experiment	74

Polynomial Inflation and Dark Matter	74
Search for a Light Pseudoscalar Higgs Boson in the Two Higgs Doublet Model using Data from the Large Hadron Collider (LHC)	75
Massless Preheating and Electroweak Vacuum Metastability	75
Searching for Electroweak Supersymmetry with the ATLAS Detector	76
Hot debate on spin polarization of Lambda hyperons	76
CMB Birefringence due to ultralight axion string networks	77
The CMS Electromagnetic Calorimeter calibration and performance during LHC Run 2	77
IceCube-Upgrade Reconstructions using Recurrent Neural Networks	78
Resonant Self Interacting Dark Mesons from Hidden QCD	78
Wormholes and black hole microstates in AdS/CFT	79
Optimization of sensitivity for the Di-Higgs search in b $B\bar{b}b\nu qq$ final state in the LHC data recorded by the ATLAS detector in pp collisions at $\sqrt{s} = 13$ TeV	79
New Low Scale Baryogenesis	80
Module Loading for the ATLAS Phase-II Inner Tracker Pixel Detector	80
Pion Production Optimization for Mu2e	81
A systematic approach to neutrino masses and their phenomenology	81
Search for Dark Matter produced in association with a Higgs boson decaying to a pair of b quarks at 13 TeV with the ATLAS detector	82
Study of energy deposition patterns in hadron calorimeter for prompt and displaced jets using convolutional neural network	82
Neutrino non-standard interactions revisited in effective field theories	83
Colliding light: photon fusion production at ATLAS	83
Search for charged Higgs bosons decaying via $H^\pm \rightarrow \tau^\pm \nu_\tau$ in the τ +jets and τ +lepton final states in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS experiment	83
Search for the Decay of the Higgs Boson to Charm Quarks with the ATLAS Experiment	84
Convolutional Neural Network Reconstruction of Neutrino Event Interaction Vertex in Ice- Cube	85
Reinterpretation of the ATLAS Search for Displaced Hadronic Jets with the RECAST Frame- work	85
A measurement of the $D^* \rightarrow \pi(K\pi\pi^0)$ decay channel as pertaining to the production of a W boson in association with a charm quark in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS Detector	86

Searching for a new leptophilic vector boson Z' with four-muon final state with the ATLAS detector	86
Designing adversarial machine learning techniques to tag displaced jets in the ATLAS calorimeter	87
Search for Higgs boson decays to bottom quarks in the vector boson fusion production mode with the ATLAS detector	87
“Study of QCD phenomena in Z +Heavy-Flavor jet measurements performed on Run-2 ATLAS data at $\sqrt{s} = 13$ TeV”	88
The Photon PDF within the CT18 global analysis	88
Search for Heavy (pseudo)Higgs boson A/H produced in association with a top-antitop quark pair leading to the final state with four top quarks in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector	89
Probing the standard cosmological model with the population of binary black-holes	89
The AMAC ASIC for the ATLAS ITk silicon strip detector: Results of prototype wafer testing	90
The HCCStar ASIC for the ATLAS ITk silicon strip detector: irradiation testing	90
ATLAS Educational Printables: from coloring books to cheat & fact sheets	91
Search for Higgs boson decays to invisible final states produced in vector boson fusion (+photon) with the ATLAS detector	91
ttH and ttW analysis in multileptons channel	92
Solving Adjoint QCD_2 with Asymptotic Basis Functions	92
The Singly-Charged Scalar Singlet as the Origin of Neutrino Masses	93
A last chance for kinetic mixing: Explaining $(g - 2)_\mu$ with semi-visible dark photons . . .	93
Superfluid EFT for sub-GeV dark matter detection	94
Search for di-Higgs production with ATLAS experiment in the $b\bar{b}l\nu l\nu$ final state	94
The AMAC ASIC for the ATLAS ITk silicon strip detector: design and verification	94
Theoretical Uncertainties in the Higgs Boson Pair Production in the $b\bar{b}\tau\tau$ Decay Channel	95
Searching for lepton-flavour-violating decays of the Higgs boson with the ATLAS detector	96
Upper limits on branching ratios of $\tau \rightarrow \ell\gamma\gamma$ and $\tau \rightarrow \ell X$ decays	96
Search for di-jet resonances along with an isolated charged lepton at $\sqrt{s} = 13$ TeV p-p collision with the ATLAS detector	96
The structure of an electron and calculation the actual energy of that	97
ATLAS Search for Non-Pointing and Delayed Photons	97

Reconstructing Electrons and Photons in the CMS ECAL using Graph Neural Networks.	98
Correlating Muon $g-2$ Anomaly with Neutrino Magnetic Moments	99
Triggering long-lived particles in HL-LHC and the challenges in the first stage of the trigger system	99
Higgs to two b's or not two b's: The measurement for a Standard Model Higgs boson, produced in association with a W or Z boson, decaying into a pair of b-quarks in pp collisions at 13 TeV with the ATLAS detector	100
New Physics and the Black Hole Mass Gap	100
Search for heavy resonances decaying into a W boson and a Higgs boson in final states with leptons and b-jets in 139 fb ⁻¹ of pp collisions at $\sqrt{s}=13\text{TeV}$ with the ATLAS detector	101
Constraints on anomalous Higgs boson couplings to vector bosons and fermions in its production and decay using the four-lepton final state	101
Call for Abstracts Search for pair production of vector-like quarks in the Wb+X final state using the full Run 2 dataset of pp collisions at $\sqrt{s} = 13$ TeV from the ATLAS detector	102
Using Dropout to Capture Uncertainty: A Novel Application to B-tagging	102
Muon Momentum Estimation in ProtoDUNE Using Multiple Coulomb Scattering	103
Radiation, thermal, and mechanical studies toward the design of a pion-production target for Mu2e-II	103
Adding an Energy Loss Prior to the IceCube Muon Reconstruction Algorithm	104
Using the light: A search for vector boson fusion production of the $H(\rightarrow b\bar{b})\gamma$ final state at $\sqrt{s} = 13$ TeV with the ATLAS detector	105
Search for low-energy nuclear recoil in XENON1T	105
Search for Gluino-Mediated Stop Pair Production in Events with b-jets and Large Missing Transverse Momentum Collected with the ATLAS Detector	105
Readout Tests of the ATLAS Detector's ITk Pixel System Toward the HL-LHC Upgrade	106
Celestial-Body Focused Dark Matter Annihilation Throughout the Galaxy	106
The HCCStar ASIC for the ATLAS ITk silicon strip detector: design and verification	107
A Familon Search Using the Mu2e Calibration Run	107
Algorithm design and expected performance for ATLAS Run-3 Level-1 calorimeter trigger system	108
Dark Matter Search Results from DAMIC at SNOLAB	109
Search for invisible decays of the Higgs boson and for dark matter with the ATLAS detector	109

Studies of $t\bar{t}HH$ with the CMS Detector	109
A possible mass distribution of primordial black holes implied by LIGO-Virgo	110
FPGA filter for fast tracking in the ATLAS HL-LHC trigger	110
Non-Abelian Vector Dark Matter and Lepton Anomalous Magnetic Moments	111
Deep-Learned Event Variables for Collider Phenomenology	111
The SiPM-on-tile system of the CMS HGCALE upgrade	112
The Cherenkov Telescope Array: probing fundamental Physics with the next-generation observatory for very-high-energy gamma rays	112
Photophilic hadronic axion from heavy magnetic monopoles	113
Study of inclusive Higgs-boson production at high transverse momentum in the $H \rightarrow b\bar{b}$ decay mode with the ATLAS detector	113
Stellar Shocks From Dark Matter	114
Low-mass primordial black holes as the dark matter candidate	115
Gravitational corrections to two-loop beta function in quantum electrodynamics	115
Deep Learning-based Tagger for Boosted WW(*) Semi-leptonic Decays at ATLAS	116
Silicon sensors for the CMS HGCALE upgrade	116
Thermal and electrical performance of the ATLAS strips module testing setup	116
Search for $W' \rightarrow tb$ in the all-hadronic final state with the ATLAS detector	117
Heavy flavors in global analyses of parton distribution functions of the proton	117
ATLAS pixel cluster splitting using Mixture Density Network	118
Axion-like Particle Searches at Rare Nuclear Isotope Accelerator Facilities	118
The LDMX Trigger Scintillator system	119
Search for Resonant and Non-Resonant VHH Production	119
Self-interacting dark matter from late decays and the H_0 tension	120
Using Photosensitive Dopants to Enhance Large LArTPC Performance	120
Search for top squark production in fully-hadronic final states in proton-proton collisions at $\sqrt{s}=13$ TeV	121
Yukawa couplings from magnetized tori	121
Axion-like Particle Searches in the Laboratory	122
Development of a High-Speed Hit Decoder for the RD53B Chip	122
Metaplectic Flavor Symmetries from Magnetized Torus	123

Implementation of Jupyter Notebooks into The Reproducible Open Benchmarks for Data Analysis Platform (ROB)	123
Muon-electron scattering at NNLO for the MUonE experiment	124
Searching for ultralight bosons using black hole spins measured from gravitational waves	125
Parity, not Peccei-Quinn, to Solve Strong CP	125
Joint Isotope-Dependent Analysis of the Daya Bay and PROSPECT Reactor Antineutrino Spectra	126
Multi-TeV Signals of Baryogenesis in Higgs Troika Model	126
Beyond the Standard Model Physics Prospects at DUNE	127
Status of the Measurement of Neutrino-Electron Elastic Scattering in the NOvA Near Detector	127
Latest axion search results from ADMX	128
Linearized Optimal Transport for Jet Physics	128
Fast RNN Inference on an FPGA	129
The NOvA Test Beam Program	129
Measurement of proton and deuteron electric dipole moments using the prototype electric dipole moment ring (PTR)	130
Improved Treatment of Dark Matter Capture in Neutron Stars: Leptonic and Baryonic Targets	130
Multi-component multiscatter capture of Dark Matter	131
Using Underground Nuclear Accelerators in the Quest for Dark Matter	131
Backgrounds and Shielding for SuperCDMS SNOLAB	132
The THDMa and possible e^+e^- signatures	132
Benchmarks from the Two Real Singlet Extension	133
Understanding Q-balls and Q-shells Analytically	133
The CMS GE1/1 commissioning and alignment status	134
A Neutron-induced Background Mitigation Study for Axion-like Particle Search at Rare Nuclear Isotope Accelerator Facilities	134
Detector performance and Data Quality monitoring at the NOvA Experiment	135
Effects of Primordial Black Holes on Dark Matter Models	135
Asymmetric Reheating by Primordial Black Holes	136
Mu2e Straw Tube Tracker Pre-Production Panel Performance Studies	136

Probing MeV-Range Scalar Bosons and TeV Range Vectorlike Fermions Associated with $U(1)_{T_{3R}}$ at the LHC	137
Reconstructing proton-proton collision positions at the Large Hadron Collider with a D-Wave quantum computer	137
Muonium-antimuonium oscillations in effective field theory	138
Triple Higgs production in and beyond the SM at proton-proton colliders	138
Total Neutron Cross Section Measurement with a 3D Projection Scintillator Tracker for Long-baseline Neutrino Experiments	139
Recent Astroparticle and Beyond the Standard Model Results from MicroBooNE	139
Unifying Gravity and Electromagnetism	140
Neural Network-based Resolutions for Pion Energy Calibration with the ATLAS Detector	140
Quantum Formation of Topological Defects	141
Search for Accelerator-produced Dark Matter with the Coherent CAPTAIN Mills detector	141
All-Hadronic search for Vector-Like Quarks using the BESTagger with 137 fb^{-1} of $\sqrt{s} = 13$ TeV proton-proton collisions collected by CMS	142
Dark Matter and Reactor CEvNS Physics Reach with SBC Liquid Argon Bubble Chambers	142
Gravitational Waves from Early Universe Turbulence	143
Overview of the GRAMS (Gamma-Ray and AntiMatter Survey) Project	143
Measurement of the complete top-quark polarization vector in t-channel single-top-quark production with ATLAS detector	144
Lorentz violation in the quark sector	144
Self-interacting neutrinos as a solution(?) to the Hubble tension	145
Diluting SUSY flavour problem on the Landscape	145
Freezing In with Lepton Flavored Fermions	146
A fresh look at proton decay in SUSY SU(5)	146
Majorana neutrino masses by D-brane instanton effects and Modular transformations . .	147
Leptogenesis from $SU(5)$ GUT with \mathcal{T}_{13} Family Symmetry	147
Updated status of the gluino searches in pMSSM in the light of latest LHC data and Dark Matter constraints	148
g-2 Dark Sector Portal: $U(1)_{\{L\mu-L\tau\}}$ Solution to Dark Matter	148
Branching fractions and CP asymmetries of $D_s^+ \rightarrow h^+ h^0$ at Belle	149
A Novel Scintillator Detector for the Mu2e-II Experiment and a Muon Tomography Probe of the Interior of the Great Pyramid	149

Direction Reconstruction using a CNN for GeV-Scale Neutrinos in IceCube	150
System for on-Axis Neutrino Detection (SAND) as part of the DUNE near detector . . .	150
HeRALD: Dark Matter Direct Detection with Superfluid 4He	151
Probing non-standard neutrino interactions with low energy neutrino-electron elastic scattering in reactor experiments	151
Design and studies for the Mu2e-II tracker	152
Directly Probing the Higgs-top Coupling at High Scales	152
Continuum-Mediated Self-Interacting Dark Matter	153
Construction of LHCb's Upstream Tracker	153
Explaining the MiniBooNE Excess Through a Mixed Model of Oscillation and Decay . .	153
Todd BSM test	154
The Mu2e Experiment: A Search for Charged Lepton Flavor Violation	154
Discovering new forces with gravitational waves from supermassive black holes	155
Heavy leptons and the muon anomalous magnetic moment	155
The CASPER and SHAFT searches for ultralight axion-like dark matter	156
The Future of High-Energy Astrophysical Neutrino Flavor Measurements	156
Improvements to Cosmic Muon Identification Using Machine Learning	157
Calibration of the Mu2e absolute momentum scale using $\pi^+ \rightarrow e^+ \nu$	157
Constraining neutrino interaction model parameters in NOvA	158
Polynomial Noise Subtraction in Lattice QCD	158
Search for CP violation using T-odd triple product asymmetries and measurement of branching fraction for decay $D^0 \rightarrow K_s^0 K_s^0 \pi^+ \pi^-$	159
Di-Higgs observation as a probe of Higgs self-coupling	159
A search for dark matter using sub- PeV γ -rays observed by Tibet AS γ	160
Vertex Reconstruction with ATLAS Inner Detector and Inner Tracker	160

Phenomenology of T-odd jet function	169
One-loop determinant for massive vector field in large dimension limit	169
New Contributions to Flavour Observables from Left-Right Symmetric Models with Uni- versal Seesaw	170
Off-shell Higgs Couplings in $H^* \rightarrow ZZ \rightarrow \ell\ell\nu\nu$	170
Data-Driven cross checks for electron neutrino selection efficiency in NOvA	170
Measurement of the $\langle \sigma \rangle$ spin correlations, top quark polarization and related angular vari- ables	171
Simulation of the Cosmic Ray Background for the Mu2e Experiment	171
Neutron beam test with 3D-projection scintillator tracker prototypes for long-baseline neu- trino oscillation experiments at Los Alamos National Laboratory	172
Precision timing with the CMS barrel MIP timing detector	172
Charged Higgs Prospects In Extended Gauge Models	173
Characterization of Multi-Pixel Photon Counters for the T2K near detector upgrade	173
Jet Timing for LLP Searches	174
Dark Matter Absorption via Electronic Excitations Revisited	174
Predictions for the Leptonic Dirac CP-Violating Phase	175
The Heavy Photon Search experiment: summary and recent developments for the 2019 Data Run	175
Latest Reactor Antineutrino Spectrum and Boosted Dark Matter Results from PROSPECT	176

Physics Opportunities with a PROSPECT Upgrade	176
Measurement of the Charged Current ν_e Interaction Cross Section on Water with the T2K π^0 Detector	177
$U(1)_{T3R}$ extension of Standard Model	177
Cosmological collider physics beyond the inflationary Hubble scale	178
Searching for Long-Lived Dark Photons with the Heavy Photon Search Experiment	178
Dark Radiation from Spinning PBHs in the Early Universe - Precision Calculation and Con- straints	179
A Joint Analysis of the PROSPECT and STEREO ^{235}U Antineutrino Spectra	179
Windchime: Gravitational Direct Detection of Dark Matter	180
Particle Instance Identification Using a Sparse 3D Convolutional Neural Network	180
Strong First-Order Electroweak Phase Transitions in the Standard Model with a Singlet Extension	181
Controlling relaxation of nuclear spin qubit ensembles for a more sensitive search for axion- like dark matter	181
Sensitivity studies of Dark Matter and CP Violation at REDTOP	182
Searches for new resonant phenomena in final states with two quarks using the ATLAS detector	182
Particle Detection utilizing Modified Bandgap Reference Circuit Design	183
Gas-rich dwarf galaxies as powerful sub-GeV dark matter detectors	183
The T2K Oscillation Analysis and Future Prospects	183
Search for heavy fermionic partner of the top quark with charge 5/3 in the single leptonic channel using CMS Run 2 Data	184
Reactor Position Reconstruction Study with PROSPECT	184
The HGCAL upgrade of the CMS detector for HL-LHC	185
Electroweak pMSSM Reinterpretation of ATLAS Searches for SUSY	185
The Design and Integrated Performance of SPT-3G	186
RNN-based track finding in the Fermilab Muon $g-2$ experiment	186
Muon conversions with flavor changing Rayleigh operators	187
Improved Background Rate and Coincident Event Removal in SuperCDMS HVeV Run 3	187
Study of neutrino-nucleus interactions with ANNIE experiment	188
Measurement of $B \rightarrow D^{**}l\nu$ branching fraction using Belle data	188

A cosmological dark matter collider experiment	189
Search for $B_0 \rightarrow \tau \pm \ell \mp$ ($\ell = e, \mu$) with a hadronic tagging method at Belle	189
Accessibility considerations for resuming in-person conferences	190
Search for chargino pair-production and chargino-neutralino production with R -Parity Violating decays in pp collisions at $\sqrt{s} = 13$ TeV with ATLAS	190
Global First of Direct Dark Matter Effective Field Theories with GAMBIT	190
Implementation of Machine Learning Algorithms to Form Di-Muons from Off-Shell Parent Particles	191

Particle Detectors / 5**Progress on construction and qualification tests of the Mu2e electromagnetic calorimeter mechanical structures****Authors:** Daniele Paciuto¹; Simone Donati²¹ *Istituto Nazionale di Fisica Nucleare - Pisa*² *University of Pisa and Istituto Nazionale di Fisica Nucleare***Corresponding Author:** daniele.pasciuto@pi.infn.it

The “muon-to-electron conversion”(Mu2e) experiment at Fermilab will search for the Charged Lepton Flavour Violating neutrino-less coherent conversion of a muon into an electron in the field of an aluminum nucleus. The observation of this process would be the unambiguous evidence of physics beyond the Standard Model. Mu2e detectors comprise a straw-tracker, an electromagnetic calorimeter and an external veto for cosmic rays. The calorimeter provides excellent electron identification, complementary information to aid pattern recognition and track reconstruction, and a fast calorimetric online trigger. The detector has been designed as a state-of-the-art crystal calorimeter and employs 1340 pure Cesium Iodide (CsI) crystals readout by UV-extended silicon photosensors and fast front-end and digitization electronics. A design consisting of two identical annular matrices (named “disks”) positioned at the relative distance of 70 cm downstream the aluminum target along the muon beamline satisfies the Mu2e physics requirements.

The hostile Mu2e operational conditions, in terms of radiation levels (total ionizing dose of 12 krad and a neutron fluence of 5×10^{10} n/cm² @ 1 MeVeq (Si)/y), magnetic field intensity (1 T) and vacuum level (10^{-4} Torr) have posed tight constraints on the design of the detector mechanical structures and materials choice. The support structure of the two 670 crystal matrices employs two aluminum hollow rings and parts made of open-cell vacuum-compatible carbon fiber. The photosensors and service front-end electronics for each crystal are assembled in a unique mechanical unit inserted in a machined copper holder. The 670 units are supported by a machined plate made of vacuum-compatible plastic material. The plate also integrates the cooling system made of a network of copper lines flowing a low temperature radiation-hard fluid and placed in thermal contact with the copper holders to constitute a low resistance thermal bridge. The data acquisition electronics is hosted in aluminum custom crates positioned on the external lateral surface of the two disks. The crates also integrate the electronics cooling system as lines running in parallel to the front-end system.

In this talk we will review the constraints on the calorimeter mechanical structures design, the development from the conceptual design to the specifications of all the structural components, including the mechanical and thermal simulations that have determined the materials and technological choices and the specifications of the cooling station, the status of components production, the components quality assurance tests, the detector assembly procedures, and the procedures for detector transportation and installation in the experimental area.

Education and Outreach / 6**THE ITALIAN SUMMER STUDENTS PROGRAM AT THE FERMI NATIONAL ACCELERATOR LABORATORY****Authors:** Daniele Paciuto¹; Simone Donati²¹ *Istituto Nazionale di Fisica Nucleare - Pisa*² *University of Pisa and Istituto Nazionale di Fisica Nucleare***Corresponding Author:** daniele.pasciuto@pi.infn.it

Since 1984 the Italian groups of the Istituto Nazionale di Fisica Nucleare (INFN) and Italian Universities, collaborating with the DOE laboratory of Fermilab (US) have been running a two-month summer training program for Italian university students. While in the first year the program involved only four physics students of the University of Pisa, in the following years it was extended to engineering students. This extension was very successful and the engineering students have been

since then extremely well accepted by the Fermilab Technical, Accelerator and Scientific Computing Division groups. Over the many years of its existence, this program has proven to be the most effective way to engage new students in Fermilab endeavors. Many students have extended their collaboration with Fermilab with their Master Thesis and PhD.

Since 2004 the program has been supported in part by DOE in the frame of an exchange agreement with INFN. An additional agreement for sharing support for engineers of the School of Advanced Studies of S. Anna (SSSA) of Pisa was established in 2007 between SSSA and Fermilab. In the frame of this program four SSSA students are supported each year. Over its 35 years of history, the program has grown in scope and size and has involved more than 500 Italian students from more than 20 Italian Universities, Since the program does not exclude appropriately selected non-italian students, a handful of students of European and non-European Universities were also accepted in the years. Each intern is supervised by a Fermilab Mentor responsible for performing the training program. Training programs spanned from Tevatron, CMS, Muon (g-2), Mu2e and SBN design and experimental data analysis, development of particle detectors (silicon trackers, calorimeters, drift chambers, neutrino and dark matter detectors), design of electronic and accelerator components, development of infrastructures and software for tera-data handling, research on superconductive elements and on accelerating cavities, theory of particle accelerators.

Since 2010, within an extended program supported by the Italian Space Agency and the Italian National Institute of Astrophysics, a total of 30 students in physics, astrophysics and engineering have been hosted for two months in summer at US space science Research Institutes and laboratories.

In 2015 the University of Pisa included these programs within its own educational programs. Accordingly, Summer School students are enrolled at the University of Pisa for the duration of the internship and are identified and ensured as such. At the end of the internship the students are required to write summary reports on their achievements. After positive evaluation by a University Examining Board, interns are acknowledged 6 ECTS credits for their Diploma Supplement.

Information on student recruiting methods, on training programs of recent years and on final student's evaluation process at Fermilab and at the University of Pisa will be given in the presentation.

The Light Dark Matter eXperiment, LDMX

Author: Valentina Dutta¹

¹ *Univ. of California Santa Barbara (US)*

Corresponding Author: valentina.dutta@cern.ch

The constituents of dark matter are still unknown, and the viable possibilities span a very large mass range. Specific scenarios for the origin of dark matter sharpen the focus on a narrower range of masses: the natural scenario where dark matter originates from thermal contact with familiar matter in the early Universe requires the DM mass to lie within about an MeV to 100 TeV. Considerable experimental attention has been given to exploring Weakly Interacting Massive Particles in the upper end of this range (few GeV – TeV), while the region ~MeV to ~GeV is largely unexplored. Most of the stable constituents of known matter have masses in this lower range, tantalizing hints for physics beyond the Standard Model have been found here, and a thermal origin for dark matter works in a simple and predictive manner in this mass range as well. It is therefore a priority to explore. If there is an interaction between light DM and ordinary matter, as there must be in the case of a thermal origin, then there necessarily is a production mechanism in accelerator-based experiments. The most sensitive way, (if the interaction is not electron-phobic) to search for this production is to use a primary electron beam to produce DM in fixed-target collisions. The Light Dark Matter eXperiment (LDMX) is a planned electron-beam fixed-target missing-momentum experiment that has unique sensitivity to light DM in the sub-GeV range. This contribution will give an overview of the theoretical motivation, the main experimental challenges and how they are addressed, as well as projected sensitivities in comparison to other experiments.

Beyond Standard Model / 8**The Higgs and Leptophobic Force at the LHC****Authors:** Elliot Golias¹; Pavel Fileviez Perez¹; Alexis Plascencia¹; Clara Murgui^{None}¹ *Case Western Reserve University***Corresponding Author:** ebg23@case.edu

The Higgs boson could provide the key to discover new physics at the Large Hadron Collider. We investigate novel decays of the Standard Model (SM) Higgs boson into leptophobic gauge bosons which can be light in agreement with all experimental constraints. We study the associated production of the SM Higgs and the leptophobic gauge boson that could be crucial to test the existence of a leptophobic force. Our results demonstrate that it is possible to have a simple gauge extension of the SM at the low scale, without assuming very small couplings and in agreement with all the experimental bounds that can be probed at the LHC (ArXiv: 2003.09426)

Astroparticles and CMB / 9**Ultra-High-Energy Tau Neutrino Cross Sections with GRAND and POEMMA****Author:** Peter Denton¹**Co-author:** Yves Kini²¹ *Brookhaven National Laboratory*² *University of Amsterdam***Corresponding Author:** peterbd1@gmail.com

Next generation neutrino experiments will push the limits in our understanding of astroparticle physics in the neutrino sector to energies orders of magnitude higher than the current state-of-the-art high-energy neutrino experiment, IceCube. These experiments will use neutrinos to tell us about the most extreme environments in the universe, while simultaneously leveraging these extreme environments as probes of neutrino properties at the highest energies accessible in the foreseeable future: $E \sim 10^9$ GeV. At these energies neutrinos are readily absorbed in the Earth. Assuming an isotropic distribution, by looking at how the flux varies as a function of angle through the Earth, we show that it is possible to extract the $\nu_\tau - N$ cross section with precision at the $\sim 20\%$ level (1σ assuming Wilks' theorem) given $N_{\text{events}} \sim 100$ events.

Neutrinos / 10**CP-Violating Neutrino Non-Standard Interactions in Long-Baseline-Accelerator Data****Author:** Peter Denton¹**Co-authors:** Rebekah Pestes²; Julia Gehrlein¹ *Brookhaven National Laboratory*² *Virginia Tech*

Corresponding Author: peterbd1@gmail.com

Neutrino oscillations in matter provide a unique probe of new physics. Leveraging the advent of neutrino appearance data from NOvA and T2K in recent years, we investigate the presence of CP-violating neutrino non-standard interactions in the oscillation data. We first show how to very simply approximate the expected NSI parameters to resolve differences between two long-baseline appearance experiments analytically. Then, by combining recent NOvA and T2K data, we find a tantalizing hint of CP-violating NSI preferring a new complex phase that is close to maximal: $\phi_{e\mu}$ or $\phi_{e\tau} = 3\pi/2$ with $|\epsilon_{e\mu}|$ or $|\epsilon_{e\tau}| \sim 0.2$. We then compare the results from long-baseline data to constraints from IceCube and COHERENT.

Color-octet scalars in Dirac gaugino models with broken R symmetry

Author: Taylor Murphy¹

Co-author: Linda Carpenter¹

¹ *Ohio State University*

Corresponding Author: murphy.1573@osu.edu

We present a phenomenological investigation of color-octet scalars (sgluons) in supersymmetric models with Dirac gaugino masses that feature an explicitly broken R symmetry (R -broken models). We have constructed such models by augmenting minimal R -symmetric models with a set of supersymmetric and softly supersymmetry-breaking operators that explicitly break R symmetry. We have found new features that appear as a result of R symmetry breaking, including enhancements to extant decay rates, novel tree- and loop-level decays, and improved cross sections of single sgluon production. We have also explored constraints on these models from the Large Hadron Collider. We find that, in general, R symmetry breaking quantitatively affects existing limits on color-octet scalars, closing loopholes for light CP-odd (pseudoscalar) sgluons while perhaps opening one for a light CP-even (scalar) particle. Altogether, scenarios with broken R symmetry and two sgluons at or below the TeV scale can be accommodated by existing searches.

Picosecond Timing Layers for Future Calorimeters: Updates from the Askaryan Calorimeter Experiment (ACE)

Authors: Remy Prechelt¹; Peter Gorham¹; Christian Miki¹

¹ *High Energy Physics Group, Univ. of Hawaii at Manoa*

Corresponding Author: prechelt@hawaii.edu

We report on new results and simulations from the Askaryan Calorimeter Experiment (ACE) which uses the coherent microwave Cherenkov emission from high energy particle showers in dielectric-loaded waveguides as calorimetric timing layers with ~ 1 ps resolution. Above ACE's energy threshold, a single 5 cm thick ($1.4 X_0$) layer of ACE waveguides would provide ~ 1 ps timing resolution, 3D spatial constraints on the scale of $\sim 300 \mu\text{m} - 5 \text{ mm}$, and an additional energy measurement, making ACE a true 5D detector. When embedded inside another calorimeter technology, ACE timing layers could provide a powerful additional measurement for particle-flow reconstruction algorithms as well as unique vertexing capabilities to significantly reduce pileup. Due to thermal noise limits, ACE elements have a relatively high energy threshold so they are currently limited to ion colliders like

the EIC or future high CoM colliders like the proposed FCC-hh. ACE elements are also exceptionally radiation-hard and can provide exquisite timing precision even when deployed in the damaging far-forward region of these future experiments. We report on new simulation results from deploying ACE timing layers in the barrel and forward calorimeters at these future colliders and discuss ongoing research to further develop and improve the ACE detector concept.

Confronting muon $g-2$ in SUSY GUTs with LHC-Run3 and Dark Matter Experiments

Authors: Qaisar Shafi^{None}; Cem Salih Un¹

¹ *Bursa Uludag University*

Corresponding Author: cemsalihun@uludag.edu.tr

We explore the implications of supersymmetric grand unified theories about the muon anomalous magnetic moment (muon $g-2$). The discrepancy between the Standard Model (SM) prediction and the experiments in muon $g-2$ can be resolved by the contributions from the supersymmetric particles, and the fundamental parameter space of the muon $g-2$ resolution typically favors light sleptons ($< \sim 800$ GeV), charginos ($< \sim 900$ GeV) and LSP neutralino ($< \sim 600$ GeV). On the other hand, the current LHC experiments can probe the mass scales for the mentioned particles, and it is expected to have a stronger impact from LHC-Run3. We find that the chargino mass can be probed up to about 600 GeV, and LHC-Run3 is expected to test chargino masses up to about 700 GeV. Even though there is no direct impact on the slepton masses, these experiments are able to probe the sleptons up to about 350 GeV. However, these scales depend on the chirality of lighter slepton states, and one can still realize solutions with lighter charginos when the lighter slepton is mostly right-handed.

Nanosecond machine learning with BDT for high energy physics

Author: Ben Carlson¹

Co-authors: Stephen Thomas Roche²; Tae Min Hong²

¹ *University of Pittsburgh*

² *University of Pittsburgh (US)*

Corresponding Author: bcarlson@cern.ch

We present a novel implementation of classification using boosted decision trees (BDT) on field programmable gate arrays (FPGA). Two example problems are presented, in the separation of electrons vs. photons and in the selection of vector boson fusion-produced Higgs bosons vs. the rejection of the multijet processes. The firmware implementation of binary classification requiring 100 training trees with a maximum depth of 4 using four input variables gives a latency value of about 10ns. Implementations such as these enable the level-1 trigger systems to be more sensitive to new physics at high energy experiments. The work is described in [2104.03408].

Dark Matter / 15**Experimental signatures of a new dark matter WIMP**

Authors: Roland Allen¹; Caden LaFontaine¹; Bailey Tallman¹; Trevor Croteau¹; Spencer Ellis¹; Diego Cristancho Guerrero¹; Brandon Torres¹; Sabrina Hernandez¹; Drue Lubanski¹

¹ *Texas A&M University*

Corresponding Author: allen@tamu.edu

The WIMP proposed here yields the observed abundance of dark matter, and is consistent with the current limits from direct detection, indirect detection, and collider experiments, if its mass is $\sim 72 \text{ GeV}/c^2$. It is also consistent with analyses of the gamma rays observed by Fermi-LAT from the Galactic center (and other sources), and of the antiprotons observed by AMS-02, in which the excesses are attributed to dark matter annihilation. These successes are shared by the inert doublet model (IDM), but the phenomenology is very different: The dark matter candidate of the IDM has first-order gauge couplings to other new particles, whereas the present candidate does not. In addition to indirect detection through annihilation products, it appears that the present particle can be observed in the most sensitive direct-detection and collider experiments currently being planned.

Higgs & Electroweak Physics / 16**Higgs to charm quarks in vector boson fusion plus a photon**

Authors: Tao Han¹; Ben Carlson¹; Sze Ching Iris Leung¹

¹ *University of Pittsburgh*

Corresponding Author: szl13@pitt.edu

Experimentally probing the charm-Yukawa coupling in the LHC experiments is important, but very challenging due to an enormous QCD background. We study a new channel that can be used to search for the Higgs decay $H \rightarrow c\bar{c}$, using the vector boson fusion (VBF) mechanism with an associated photon. In addition to suppressing the QCD background, the photon gives an effective trigger handle. We discuss the trigger implications of this final state that can be utilized in ATLAS and CMS. We propose a novel search strategy for $H \rightarrow c\bar{c}$ in association with VBF jets and a photon, where we find a projected sensitivity of about 5 times the SM charm-Yukawa coupling at 95% C.L. at High Luminosity LHC (HL-LHC). Our result is comparable and complementary to existing projections at the HL-LHC. We also discuss the implications of increasing the center of mass collision energy to 30 TeV and 100 TeV.

Higgs & Electroweak Physics / 17**Quark and Gluon Contents of a Lepton at High Energies****Authors:** Yang Ma¹; Tao Han²; Keping Xie²¹ *University of Pittsburgh*² *University of Pittsburgh***Corresponding Author:** mayangluon@pitt.edu

After the triumph of discovering the Higgs boson at the CERN Large Hadron Collider, people are getting increasingly interested in studying the Higgs properties in detail and searching for the physics beyond the Standard Model (SM). A multi-TeV lepton collider provides a clean experimental environment for both the Higgs precision measurements and the discovery of new particles. In high-energy leptonic collisions, the collinear splittings of the leptons and electroweak (EW) gauge bosons are the dominant phenomena, which could be well described by the parton picture. In the parton picture, all the SM particles should be treated as partons that radiated off the beam particles, and the electroweak parton distribution functions (EW PDFs) should be adopted as a proper description for partonic collisions of the initial states. In our work, both the EW and the QCD sectors are included in the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi (DGLAP) formalism to perturbatively resum the potential large logarithms emerging from the initial-state radiation (ISR). I will show the results of QCD jet production as well as some other typical SM processes at a possible high-energy electron-positron collider and a possible high-energy muon collider obtained using the PDFs.

Dark Matter / 19**Strong constraints on thermal relic dark matter from Fermi-LAT observations of the Galactic Center****Author:** Ryan Keeley¹**Co-authors:** Kevork N. Abazajian²; Oscar Macias²; Manoj Kaplinghat³; Shunsaku Horiuchi³

¹ *Korea Astronomy Space Science Institute*

² *University of Amsterdam*

³ *Virginia Tech*

Corresponding Author: rkeeley@kasi.re.kr

The extended excess towards the Galactic Center (GC) in gamma rays inferred from Fermi-LAT observations has been interpreted as being due to dark matter (DM) annihilation. In a recent paper my collaborators and I performed a new likelihood analyses of the GC and showed that when including templates for the stellar galactic and nuclear bulges, the GC shows no significant detection of a DM annihilation template, even after generous variations in the Galactic diffuse emission (GDE) models and a wide range of DM halo profiles. We include Galactic diffuse emission models with combinations of 3D inverse Compton maps, variations of interstellar gas maps, and a central source of electrons. For the DM profile, we include both spherical and ellipsoidal DM morphologies and a range of radial profiles from steep cusps to kiloparsec-sized cores, motivated in part by hydrodynamical simulations. Our derived upper limits on the dark matter annihilation flux place strong constraints on DM properties. In the case of the pure b-quark annihilation channel, our limits on the annihilation cross section are more stringent than those from the Milky Way dwarfs up to DM masses of ~ 1 TeV, and rule out the thermal relic cross section up to ~ 300 GeV. Better understanding of the DM profile, as well as the Fermi-LAT data at its highest energies, would further improve the sensitivity to DM properties.

A Supersymmetric Flavor Clockwork

Authors: Sri Aditya Gadam¹; Wolfgang Altmannshofer²

¹ *University of California, Santa Cruz*

² *UC Santa Cruz*

Corresponding Author: sgadam@ucsc.edu

Clockwork models can explain the flavor hierarchies in the Standard Model quark and lepton spectrum. We construct supersymmetric versions of such flavor clockwork models. The zero modes of the clockwork are identified with the fermions and sfermions of the Minimal Supersymmetric Standard Model. In addition to generating a hierarchical fermion spectrum, the clockwork also predicts a specific flavor structure for the soft SUSY breaking sfermion masses. We find sizeable flavor mixing among first and second generation squarks. Constraints from Kaon oscillations require the masses of either squarks or gluinos to be above a scale of ~ 3 PeV.

Extending QED to Interactions of the Full Eight-Component Vacuum Wavefunction of the Geometric Representation of Clifford Algebra

Author: peter cameron¹

¹ *Brookhaven Lab (retired)*

Corresponding Author: electrongaugegroup@gmail.com

Clifford algebra is the math language of quantum mechanics, known to most physicists in the matrix representations of Pauli and Dirac. Less familiar (but far more intuitive) is the original geometric intent of Clifford, the algebra of interactions of fundamental geometric objects - point, line, plane, and volume elements. In geometric representation, the 3D vacuum wavefunction is comprised of one scalar point, three vector line elements (orientational degrees of freedom), three bivector area elements, and one trivector volume element. Various combinations of the four fundamental constants that define the dimensionless electromagnetic coupling constant alpha (speed of light, permittivity of space, electric charge quantum and angular momentum quantum) permit assigning geometrically and topologically appropriate electric and magnetic flux quanta to the eight wavefunction components, increasing 'dimensionality' of the model to the ten degrees of freedom of string theory. Time (quantum phase) emerges from wavefunction interactions, in the dimension-increasing property of Clifford algebra wedge products. Such a 6D Yang-Mills model is naturally gauge invariant, finite, confined, asymptotically free, background independent, and contains the four forces [1,2].

Searching for Cosmic Strings using data from the third Advanced LIGO-Virgo observing run

Author: Fengwei Yang¹

¹ *University of Utah*

Corresponding Author: fengwei.yang@utah.edu

Cosmic string network generically appears in many natural extensions of particle SM. And cosmic strings are one-dimension topological defects which can be formed in grand unified theory scale phase transitions in the early universe and are also predicted to form in the context of string theory. The main mechanism for a network of Nambu-Goto cosmic strings to lose energy is through the production of loops and the subsequent emission of GW, thus offering an experimental signature for the existence of cosmic strings. And the unresolvable GW bursts produced by cosmic strings at different loop scale and cosmic time will overlap with each other and form a stochastic GW background (SGWB). We performed the parameter estimation in three cosmic string models using the third Advanced LIGO-Virgo observation run isotropic stochastic search results. We also consider a new source component in the model, i.e. kink-kink collision, using more realistic model parameters.

New signatures of decaying HNLs in large scale detectors

Author: Ryan Plestid¹

¹ *University of Kentucky*

Corresponding Author: rpl225@uky.edu

Weakly coupled light new physics is a well motivated lamppost often referred to as a dark sector. At low masses and weak couplings, dark sector particles are generically long-lived. In this talk I will describe how neutrino-portals to a dark sector can be efficiently probed by looking for the decay of heavy neutral leptons that are produced via the upscattering of solar neutrinos within the Earth's core/mantle. Large volume detectors (such as Borexino or Super Kamiokande) can search for MeV-scale photons and electron-positrons pairs from HNLs decaying while passing through their detectors.

THz Photon Source Testing for the BREAD Experiment

Authors: Jesse Liu¹; Kristin Marie Dona²

¹ *University of Chicago*

² *University of Chicago (US)*

Corresponding Author: kristin.marie.dona@cern.ch

Detection and understanding of dark matter is one of the major unsolved problems of modern particle physics and cosmology. Several theories of fundamental physics predict bosonic dark matter candidates that can modify Maxwell's equations resulting in additional photon emission from conducting surfaces. One of these promising dark matter candidates is known as the axion, which could be detected by observing the emitted electromagnetic radiation resulting from axion-photon coupling.

The Broadband Reflector Experiment for Axion Detection (BREAD) haloscope experiment will investigate a currently underprobed dark matter parameter space using novel reflector technology. This new experiment will develop technology for a new type of wideband axion dark matter search experiment capable of detecting axions in the mass range of approximately 10 meV – 30 eV, a range

not currently accessible by other techniques. This target mass range corresponds to an observable dark matter signal in the under-probed terahertz regime.

This presentation will cover the commissioning and building of a preliminary, room-temperature, terahertz photon source testing and calibration system that is intended to be used for a prototype BREAD detector.

The REDTOP experiment: An eta/eta' factory to explore Physics Beyond the Standard Model

Author: Corrado Gatto¹

Co-author: REDTOP Collaboration on behalf of

¹ *INFN & NIU*

Corresponding Author: gatto@fnal.gov

The η and η' mesons are almost unique in the particle universe since they are Goldstone boson and the dynamics of their decay are strongly constrained. The integrated eta meson samples collected in earlier experiments have been about $\sim 10^9$ events, dominated by the WASA at Cosy experiment, limiting considerably the search for such rare decays. A new experiment, REDTOP, is being proposed, with the intent

of collecting more than 10^{13} eta/yr (10^{11} eta'/yr) for studying of rare η decays.

Such statistics are sufficient for investigating several symmetry violations, and for searches of new particles beyond the Standard Model.

With tagged-eta experiment the fully constrained kinematic of the process allows for searches of light dark matter with a "Missing 4-momentum technique" which, at present, cannot be exploited by any other existing or proposed experiment.

The physics program and the detector for REDTOP will be discussed during the presentation.

New bounds on sneutrino masses through collider searches

Authors: Humberto Gilmer¹; Linda Carpenter¹

¹ *Ohio State University*

Corresponding Author: gilmer.30@osu.edu

Though collider searches are constraining supersymmetric parameter space, generic model independent bounds on sneutrinos remain very low. We calculate new model independent lower bounds on general supersymmetric scenarios with sneutrino LSP and NLSPs. By recasting ATLAS LHC exotic searches in mono boson channels, we place an upper bound on the cross section on $pp \rightarrow \tilde{\nu}\tilde{\nu} + V$ processes in mono-photon, mono- Z and mono-Higgs channels. We also evaluate the LHC discovery potential of sneutrinos in the HL-LHC 3 ab^{-1} run.

The muon campus program at Fermilab includes the Mu2e experiment that will search for a charged-lepton flavor violating processes where a negative muon converts into an electron in the field of an aluminum nucleus, improving by four orders of magnitude the search sensitivity reached so far.

Mu2e's Trigger and Data Acquisition System (TDAQ) uses `itsdaq` as its solution. Developed at Fermilab, `itsdaq` uses the `artdaq` DAQ framework and `art` analysis framework, under-the-hood, for event transfer, filtering, and processing.

`itsdaq` is an online DAQ software suite with a focus on flexibility and scalability, while providing a multi-user, web-based, interface accessible through a web browser.

A Detector Control System (DCS) for monitoring, controlling, alarming, and archiving has been developed using the Experimental Physics and Industrial Control System (EPICS) open source Platform. The DCS System has also been integrated into `itsdaq`, providing a GUI multi-user, web-based control, and monitoring dashboard.

DUNE The Deep Underground Neutrino Experiment

Author: Melissa Uchida¹

¹ *University of Cambridge (GB)*

Corresponding Author: mauchida@hep.phy.cam.ac.uk

The Deep Underground Neutrino Experiment (DUNE) is a next-generation long-baseline neutrino experiment. Its main physics goals are the precise measurement of the neutrino oscillation parameters, in particular the violation of the charge-parity symmetry and the neutrino mass hierarchy. DUNE consists of a Far Detector (FD) complex with four multi-kiloton liquid argon detectors, and a Near Detector (ND) complex located close to the neutrino source at Fermilab (USA). Here we present an overview of the DUNE experiment, its detectors, and physics capabilities.

The Deep Underground Neutrino Experiment (DUNE) is an upcoming long-baseline neutrino experiment which will study neutrino oscillations. Neutrino oscillations will be detected at the DUNE far detector 1300 km away from the start of the beam at Fermilab. The DUNE near detector (ND) will

be located on-site at Fermilab, and will be used to provide an initial characterization of the neutrino beam, as well as to constrain systematic uncertainties on neutrino oscillation measurements. The detector suite consists of a modular 50-ton LArTPC (ND-LAr), a magnetized 1-ton gaseous argon time projection chamber (ND-Gar) surrounded by an electromagnetic calorimeter, and the System for on-Axis Neutrino Detection (SAND), composed by magnetized electromagnetic calorimeter and inner tracker. In this talk, these detectors and their physics goals will be discussed.

Performance portability of random number generation in SYCL

Author: Vincent Pascuzzi¹

¹ *Lawrence Berkeley National Lab. (US)*

Corresponding Author: vincent.pascuzzi@cern.ch

The increasing number of high-performance computing centers around the globe is providing physicists and other researchers access to heterogeneous systems – comprising multiple central processing units and graphics processing units per node – with various platforms. However, it is more often than not the case that domain scientists have limited resources such that writing multiple implementations of their codes to target the different platforms is unfeasible. To help address this, a number of portability layers are being developed that aim to allow programmers to achieve performant, portable codes; for example, Intel Data Parallel C++ (DPC++), which is based on the SYCL programming model. Nevertheless, portable application programming interfaces often lack some features and tools that are manifest in a platform-specific API. Physicists in particular rely heavily on large sets of random numbers in nearly their entire workflow, from event generation to analysis. In this talk, we detail the implementation of AMD and NVIDIA GPU support into oneMKL,

permitting random number generation within SYCL-based applications using optimized libraries. By utilizing existing optimizations and SYCL interoperability, we demonstrate the ability to achieve nearly native performance in cross-platform applications.

Progress toward building a pair of scintillating bubble chambers for WIMPs and reactor CEvNS

Author: Rocco Coppejans¹

¹ *Northwestern University*

Corresponding Author: rocco.coppejans@gmail.com

The Scintillating Bubble Chamber (SBC) is a rapidly developing new technology for 0.7 - 7 GeV nuclear recoil detection. Demonstrations in liquid xenon at the few-gram scale have confirmed that this technique combines the event-by-event energy resolution of a liquid-noble scintillation detector with the world-leading electron-recoil discrimination capability of the bubble chamber, and in fact maintains that discrimination capability at much lower thresholds than traditional Freon-based bubble chambers. The promise of unambiguous identification of sub-keV nuclear recoils in a scalable detector makes this an ideal technology for both GeV-mass WIMP searches and CEvNS detection at reactor sites. We will present progress from the SBC Collaboration towards the construction of a pair of 10-kg argon bubble chambers at Fermilab and SNOLAB to test the low-threshold performance of this technique in a physics-scale device and search for dark matter, respectively.

Fabrication of a high efficiency cosmic ray veto detector for the Mu2e experiment.

Author: Robert Group¹

¹ *University of Virginia*

Corresponding Author: rcg6p@virginia.edu

The Mu2e experiment at Fermilab will search for the charged-lepton flavor-violating process of a neutrinoless muon-to-electron conversion in the presence of a nucleus. The sensitivity goal of the experiment is four orders of magnitude below the current strongest limits on this process. This requires all backgrounds to sum to fewer than one event over the lifetime of the experiment. One major background is due to cosmic-ray muons producing electrons that fake a signal inside of the Mu2e apparatus. The Mu2e Cosmic Ray Veto (CRV) has been designed to veto these cosmic-ray backgrounds with an efficiency of approximately 99.99%, while causing a low dead time and operating in a high-intensity environment. In this talk the design is motivated, and the fabrication processes, and status, of the components of the CRV being produced at the University of Virginia are presented in detail.

NNLO single-top-quark production and decay: Discrepancies resolved, PDFs challenged

Author: Zack Sullivan¹

Co-authors: John Campbell ; Tobias Neumann ²

¹ *Illinois Institute of Technology*

² *Brookhaven National Laboratory*

Corresponding Author: zack.sullivan@iit.edu

We present our recent NNLO calculation of t-channel single-top-quark production and decay that resolves a disagreement between two previous calculations whose size at the inclusive level was comparable to the NNLO correction itself, and was even larger differentially. Moving beyond those comparisons, we have included b-quark tagging to allow for comparison with experiment, and added the ability to use double deep inelastic scattering (DDIS) scales ($\mu^2 = Q^2$ for the light-quark line and

$\mu^2 = Q^2 + m_t^2$ for the heavy-quark line) that allow for direct testing of parton distribution function (PDF) stability. All code will be publicly available in MCFM.

We demonstrate that several characteristic fiducial and differential standard model observables, and observables sensitive to new physics, are stable between NLO and NNLO, but point out there is a sizable difference in the prediction of some exclusive t+n-jet cross sections. Finally, we use this calculation to present preliminary results which indicate that some commonly used PDF sets are in significant disagreement, both with each other and with themselves between perturbative orders when evaluated at Tevatron energies.

A Novel Approach to Unsupervised Learning for Anomalous Jet Identification with a Variational Recurrent Neural Network

Author: Julia Lynne Gonski¹

¹ *Columbia University (US)*

Corresponding Author: julia.gonski@cern.ch

The search for new physics at the energy frontier has a strong model-based foundation, with well-motivated theories informing the phase space that is subsequently investigated in data. This strategy has been effective for decades in establishing the Standard Model, culminating in the 2012 discovery of the Higgs boson with the Large Hadron Collider (LHC). Recent developments in machine learning techniques motivate the complementation of current model-driven analysis programs with generic searches for unexpected new physics signals. Anomaly detection is at the essence of this pursuit, with the goal of identifying features of the data solely based on their inconsistency with a background-only model. In this talk, a novel application of a Variational Recurrent Neural Network (VRNN) to the task of anomalous jet detection is presented. This method is fully unsupervised, in that it trains directly on data and does not use a signal hypothesis. Results are shown using the LHC Olympics simulated datasets, where a VRNN-based selection is shown to enhance sensitivity to both two- and three-prong large-R jet signal excesses. Future prospects for integrating this and other unsupervised learning methods into LHC analyses are also discussed.

Testing freeze-in with Z bosons

Authors: Catarina Cosme¹; Maíra Dutra²; Stephen Godfrey²; Taylor Gray²

¹ *University of Valencia*

² *Carleton University*

Corresponding Author: taylorgray@cmail.carleton.ca

If dark matter interacts too feebly with ordinary matter, it was not able to thermalize with the bath in the early universe. Such Feebly Interacting Massive Particles (FIMPs) would therefore be produced via the freeze-in mechanism. Testing FIMPs is a challenging task, given the smallness of their couplings. In this talk, I will discuss our recent proposal of a Z' portal where freeze-in can be currently tested by many experiments. In our model, Z' bosons with masses in the MeV-PeV range have both vector and axial couplings to ordinary and dark fermions. We place constraints on our parameter space with bounds from direct detection, atomic parity violation, leptonic anomalous magnetic moments, neutrino-electron scattering, collider, and beam dump experiments.

QED radiative corrections to charged-current neutrino-nucleon elastic scattering for accelerator neutrino experiments

Authors: Chen Qing¹; Kevin McFarland²; Oleksandr Tomalak¹; Richard J Hill¹

¹ *University of Kentucky*

² *University of Rochester*

Corresponding Author: oleksandr.tomalak@uky.edu

Charged-current quasielastic scattering is the signal process in modern neutrino oscillation experiments. It also serves as the main tool for the reconstruction of the incoming neutrino energy. Exploiting effective field theory, we factorize neutrino-nucleon quasielastic cross sections into soft, collinear, and hard contributions. We evaluate soft and collinear functions from QED and provide a model for the hard contribution. Performing resummation, we account for logarithmically-enhanced higher-order corrections and evaluate cross sections and cross-section ratios quantifying the resulting error. We discuss the relevance of radiative corrections depending on conditions of modern and future accelerator-based neutrino experiments.

Search for Vector-Like-Quarks T/B in Same-Sign Dilepton and Multi-lepton Final States at $\sqrt{s} = 13$ TeV

Authors: Emanuele Usai¹; Jess Wong¹; Julie Hogan^{None}; Meenakshi Narain¹; Rizki Syarif¹; Sinan Sagir¹; Ulrich Heintz¹

¹ *Brown University (US)*

Corresponding Author: wing.yan.wong@cern.ch

The discovery of a Higgs boson with mass near 125 GeV in 2012 marked one of the most important milestones in particle physics. The low mass of this Higgs boson with diverging loop corrections adds motivation to look for new physics Beyond the Standard Model (BSM). Several BSM theories introduced new heavy quark partners, called vector-like quarks (VLQ), with mass at the TeV scale.

In particular, the vector-like top quark (T) can cancel the largest correction due to the top quark loop, which is one of the main contributions to the divergence, and stabilize the scalar Higgs boson mass. This analysis searches for pair production of vector-like T or B quarks with charge $2e/3$ and $e/3$ in proton-proton collisions at 13 TeV at the LHC. Theories predict 3 decay modes for T and B, respectively: bW , tZ , tH and tW , bZ , bH . The branching ratios vary over different theoretical models. We focus on events where bosons decay leptonically and result in a final state with a same-sign (SS) di-lepton pair and a final state with multiple (3 or more) leptons. We analyze data collected by the CMS detector in the LHC in 2017 and 2018 with integrated luminosities of 41.5 and 59.7 fb^{-1} . Besides Standard Model (SM) processes with the same final states, lepton misidentification contributes a significant part of the background to both SS dilepton and multilepton channel and is estimated by a data-driven method. In addition, charge mis-identification is another source of background for SS dilepton channel, which is also estimated by a data-driven method. Comparing the estimated background with data, and considering uncertainties, we determine an upper limit on the TT or BB production cross section. We calculate limits at different mass points of T and B and different branching fraction combinations.

Search for top squarks in final states with two top quarks and several light-flavor jets in proton-proton collisions at $\sqrt{s} = 13$ TeV

Author: Semra Turkcapar¹

¹ Cukurova University (TR)

Corresponding Author: semra.turkcapar@cern.ch

A search is presented for new physics beyond the standard model, including versions of Supersymmetry characterized by R-parity Violating (RPV) and Stealth SUSY. The result of this search is in events with two top quarks, no extra transverse momentum, and many light flavor jets as a final state of the top squark. The Run2 data used were collected with the CMS detector at the LHC in 2016 to 2018, and correspond to a total integrated luminosity of 137 fb^{-1} . The search is performed using events with at least seven jets and exactly one electron or muon. A neural network based on event shape and kinematical variables is used for background discrimination. The method of gradient reversal is used to ensure that the neural network score is independent of jet multiplicity as required by the primary background estimation method. Top squark masses up to 670 (870) GeV are excluded at 95% confidence level for the RPV (stealth) scenario, and the maximum observed local significance is 2.8 standard deviations for the RPV scenario with top squark mass of 400 GeV.

Search for vector boson scattering production of VW pairs in the semi-leptonic channel at CMS

Author: Flavia Cetorelli¹

¹ *Universita & INFN, Milano-Bicocca (IT)*

Corresponding Author: flavia.cetorelli@cern.ch

The search for the electroweak VBS production of a VW pair plus two jets in the semi-leptonic final state is presented. The full CMS dataset (137.1 fb⁻¹) for the LHC Run II of proton-proton collisions at a center-of-mass energy of 13 TeV is analyzed. In the final state, we expect two well-separated jets with a high invariant mass, one lepton from the W boson decay, and the decay products of the W/Z boson. Jets arising from the hadronic decay of vector bosons could be reconstructed either as two additional jets, with invariant mass near the W/Z mass, or as one jet with a larger radius in the case of a boosted decay. The main background arises from the single W production plus jets, which is measured in dedicated control regions with a data-driven strategy. The implementation of sophisticated machine learning techniques enhances the discrimination of the signal from these overwhelming backgrounds.

Search for new particles in events with energetic jets and large missing transverse momentum in proton-proton collisions at $\sqrt{s} = 13$ TeV

Author: Siqi Yuan¹

¹ *Boston University (US)*

Corresponding Author: siqi.yuan@cern.ch

A search is presented for new particles in proton-proton collisions at $\sqrt{s} = 13$ TeV at the LHC, using events with energetic jets and large missing transverse momentum. The analysis is based on a data sample corresponding to an integrated luminosity of 101 fb⁻¹, collected in 2017–2018 with the CMS

detector. Separate categories are defined for events with narrow jets from initial-state radiation and with large-radius jets consistent with a hadronic decay of a W or a Z boson. Novel machine learning techniques are used to identify hadronic W and Z boson decays, allowing for a significant improvement of the analysis sensitivity compared with earlier results. The analysis is combined with an earlier search based on a data sample corresponding to an integrated luminosity of 36 fb^{-1} , collected in 2016. No significant excess of events is observed with respect to the standard model background expectation, as determined from control samples in data. The results are interpreted in terms of limits on the branching fraction of an invisible decay of the Higgs boson, as well as constraints on simplified models of dark matter, on first-generation scalar leptoquarks decaying to quarks, and neutrinos, and on gravitons in models with large extra dimensions. Several of the new limits are the most restrictive to date.

The R-parity Violating Decays of Charginos and Neutralinos in the B-L MSSM

Author: Sebastian Dumitru¹

¹ *University of Pennsylvania*

Corresponding Author: sdumitru@sas.upenn.edu

The R-parity violating decays of Wino charginos, Wino neutralinos and Bino Neutralinos LSPs are analyzed within the context of the B - L MSSM “heterotic standard model”. These LSPs correspond to statistically determined initial soft supersymmetry breaking parameters which, when evolved

using the renormalization group equations, lead to an effective theory satisfying all phenomenological requirements; including the observed electroweak vector boson and Higgs masses. The explicit decay channels of these LSPs into standard model particles, the analytic and numerical decay rates and the associated branching ratios are presented. The decay lengths of these RPV interactions are discussed. It is shown that the vast majority of these decays are “prompt”, although a small, but calculable, number correspond to “displaced vertices” of various lengths. The relation of these results to the neutrino hierarchy—either normal or inverted—is discussed in detail.

Cosmological Simulations of Axion String Radiation

Author: Joshua Foster¹

¹ *University of Michigan*

Corresponding Author: fosterjw@umich.edu

The QCD axion represents a well-motivated new physics candidate capable of explaining dark matter and the absence of the neutron electric dipole moment. If realized after the breaking of a Peccei-Quinn symmetry after the end of inflation, the late-time number density of axions is jointly determined by radiation of axions from topological defects known as strings and from the dynamics of the axion field as it acquires a mass through the QCD phase transition. Here I present the results of simulations of axion radiation from strings using the block-structured adaptive mesh refinement code AMReX, which greatly extends the dynamical range of conventional simulation techniques, towards a precise determination of the mass of the QCD axion which produces the observed relic abundance of dark matter.

⁴ *SLAC National Accelerator Laboratory (US)*

⁵ *SLAC/Stanford*

⁶ *Hebrew University*

Corresponding Author: ytc@stanford.edu

We present the theoretical case along with some early measurements with diamond test chips that demonstrate the viability of TES on diamond as a potential platform for direct detection of sub-GeV dark matter.

Diamond targets can be sensitive to both nuclear and electron recoils from dark matter scattering in the MeV and above mass range, as well as to absorption processes of dark matter with masses between sub-eV to 10's of eV.

Compared to other proposed semiconducting targets such as germanium and silicon, diamond detectors can probe lower dark matter masses via nuclear recoils due to the lightness of the carbon nucleus. The expected reach for electron recoils is comparable to that of germanium and silicon, with the advantage that dark counts are expected to be under better control. Via absorption processes, unconstrained QCD axion parameter space can be successfully probed in diamond for masses of order 10^{\sim}eV .

Detectors based on Chemical Vapor Deposition (CVD) diamond have been used successfully in beam conditions monitors in the highest radiation areas of the LHC. Future experiments at CERN will accumulate an order of magnitude larger fluence. As a result, an enormous effort is underway to identify detector materials that can operate after fluences of $10^{16}/\text{cm}^2$ and $10^{17}/\text{cm}^2$.

Diamond is one candidate due to its large displacement energy that enhances its radiation tolerance. Over the last 2 years the RD42 collaboration has constructed 3D CVD diamond detectors that use laser fabricated columns to enhance radiation tolerance. The cells in these detectors had a size of $50\mu\text{m} \times 50\mu\text{m}$ with columns $2.6\mu\text{m}$ in diameter. The beam test results for both un-irradiated and irradiated detectors will be presented.

Latest Results on the Radiation Tolerance of Diamond Detectors

Authors: Harris Kagan¹; William Trischuk²; Lukas Baeni³

¹ *O*

² *University of Toronto (CA)*

³ *ETH Zurich (CH)*

Corresponding Authors: lukas.baeni@cern.ch, william.trischuk@cern.ch

As nuclear and particle physics facilities move to higher intensities, the detectors used there must be more radiation tolerant. Diamond is in use at many facilities due to its inherent radiation tolerance and ease of use. We will present radiation tolerance measurements of the highest quality poly-crystalline Chemical Vapor Deposition (pCVD) diamond material for irradiations from a range of proton energies, pions and neutrons up to a fluence of 2×10^{16} particles/cm². We have measured the damage constants as a function of energy and particle species and compare with theoretical models. We also present measurements of the rate dependence of pulse height for non-irradiated and irradiated pCVD diamond pad and pixel detectors, including detectors tested over a range of particle fluxes up to 20 MHz/cm² with both pad and pixel readout electronics. Our results indicate the pulse height of unirradiated and neutron irradiated pCVD diamond detectors is not dependent on the particle flux.

QED Model of Massless Neutrino Oscillation in the Geometric Representation of Clifford Algebra

Author: peter cameron¹

¹ *Brookhaven Lab (retired)*

Corresponding Author: electrongaugegroup@gmail.com

All experimental data is consistent with massless neutrinos. There exist possibilities other than rest mass differences to explain oscillation. The two-component photon wavefunction is comprised of electric and magnetic flux quanta, coupled by Maxwell's equations. In the basic photon-electron interaction of QED, opposing phase shifts of the electron's inductive and capacitive impedances decouple the photon's flux quanta, breaking Maxwell's equations, transferring energy and momentum. Extending the two-component Dirac wavefunction (scalar charge and bivector magnetic moment) to the full eight-component vacuum wavefunction in the geometric representation of Clifford algebra permits assigning topological magnetic charge to the spin 1 3D pseudoscalar. A simple three-component neutrino wavefunction model might then be comprised of the two photon components, topologically protected by magnetic charge. Curiously, in SI units 1D vector magnetic flux quantum and 3D trivector magnetic charge quantum are numerically identical yet geometrically and topologically distinct. We discuss the mixing matrix that results from such a model. <https://indico.fnal.gov/event/19348/contributions/186426/>

To address the challenges of providing high performance calorimetry and other types of instrumentation in future experiments under high luminosity and difficult radiation and pileup conditions, R&D is being conducted on promising optical-based technologies that can inform the design of future detectors, with emphasis on ultra-compactness, excellent energy resolution and spatial resolution, and especially fast timing capability.

The strategy builds upon the following concepts: use of dense materials to minimize the cross sections and lengths (depths) of detector elements; maintaining Molière Radii of the structures as small as possible; use of radiation-hard materials; use of optical techniques that can provide high efficiency and fast response while keeping optical paths as short as possible; and use of radiation resistant, high efficiency photosensors.

High material density is achieved by using thin layers of tungsten absorber interleaved with active layers of dense, highly efficient crystal or ceramic scintillator. Several scintillator approaches are currently being explored, including rare-earth 3+ activated materials Ce³⁺ and Pr³⁺ for brightness and Ca co-doping for improved (faster) fluorescence decay time.

Light collection and transfer from the scintillation layers to photosensors is enabled by the development and refinement of new waveshifters (WLS) and the incorporation of these materials into radiation hard quartz waveguide elements. WLS dye developments include fast organic dyes of the DSB1 type, ESIPT (excited state intermolecular proton transfer) dyes having very large Stokes' Shifts and hence very low optical self-absorption, and inorganic fluorescent materials such as LuAG:Ce, which is noted for its radiation resistance.

Optical waveguide approaches include quartz capillaries containing WLS cores to: (1) provide high resolution EM energy measurement; (2) with WLS materials strategically placed at the location of the EM shower maximum to provide high resolution timing of EM showers, and (3) with WLS shifter elements placed at various depth locations to provide depth segmentation and angular measurement of the EM shower development.

Light directly from the scintillators or indirectly via wave shifters is detected by pixelated, Geiger-mode photosensors that have high quantum efficiency over a wide spectral range and designed to avoid saturation. These include the development of very small pixel (5-7 micron) silicon photomultiplier devices (SiPM) operated at low gain and cooled (typically -35°C or below), and longer-term R&D on photosensors based upon large band-gap materials including GaInP. Both efforts are directed toward improved device performance in high radiation fields.

The main emphases of the RADiCAL R&D program are: (1) the bench, beam and radiation testing of individual scintillator, wave shifter and photo sensing elements; and (2) by combining these into ultra-compact modular structures, to characterize and assess their performance for measurement of energy, fast timing, and depth segmentation. Recent results and program plans will be presented.

Computation, Machine Learning, and AI / 58**Unfolding ATLAS Collider Data with the Novel OmniFold Procedure****Authors:** Adi Suresh¹; Benjamin Nachman²¹ *University of California, Berkeley*² *Lawrence Berkeley National Laboratory***Corresponding Author:** adisurtya@berkeley.edu

To perform theoretical calculations and comparisons with collider data, it must first be corrected for various detector effects, namely noise processes, detector acceptance, detector distortions, and detector efficiency; this process is called “unfolding” in high energy physics (or “deconvolution” elsewhere). While most unfolding procedures are carried out over only one or two binned observables at a time, OmniFold is a simulation-based maximum likelihood procedure which employs deep learning to do unbinned and (variable-, and) high-dimensional unfolding. We apply OmniFold to a measurement of all charged particle properties in Z +jets events using the full Run 2 pp collision dataset recorded by the ATLAS detector to complete the first application of OmniFold on physical collider data.

Gravity and Gravitational Waves / 59**On a rigorous Framework for a Quantum N-Body Theory on curved Spacetime****Authors:** Maik Reddiger¹; Bill Poirier¹¹ *Texas Tech University***Corresponding Author:** maik.reddiger@ttu.edu

The construction of a mathematically rigorous relativistic quantum theory has so far remained elusive. Within the ‘axiomatic quantum field theory in curved spacetime’ research program it has been acknowledged that such a theory needs to be compatible with the general-relativistic conception of a spacetime. That is, one may not rely on the symmetries of Minkowski spacetime in formulating the axioms of such a theory, even if one is merely interested in the special-relativistic case. In the aforementioned approach mathematical physicists thus attempted to generalize the Wightman axioms to the general-relativistic setting.

In this work, we pursue a more direct and arguably more physical ansatz by generalizing the N -body Born rule from non-relativistic quantum mechanics to curved spacetime. We first review the one-body case, closely tied to the mathematical theory of the relativistic continuity equation, and then generalize the general-relativistic spacetime concept to the case of N -bodies (with ‘fixed background’). We show how the conservation of probability therein is mathematically tied to the validity of a scalar many-body continuity equation—as one would a priori expect. If it holds, the integrand for calculating the respective detection probability turns out to be an absolute invariant in the sense of Poincaré-Cartan, so that a ‘preferred spacetime splitting’ is not required.

The general-relativistic N -body Born rule presented here allows one to infer important, structural aspects of a rigorous relativistic quantum theory, and it provides an essential step towards the more general case in which N is allowed to vary. The formalism overcomes some problems of related approaches in the literature, including the use of non-canonical geometric structures and overly restrictive causal/topological conditions (see Reddiger & Poirier, arXiv:2012.05212 [Math-Ph] (2020)).

Searches for long-lived particles with the CMS experiment

Author: Karri Folan Di Petrillo¹

¹ *Fermi National Accelerator Lab. (US)*

Corresponding Author: karri.folan.di.petrillo@cern.ch

Most searches for new physics at the Large Hadron Collider assume that a new particle produced in pp-collisions decays almost immediately or is non-interacting and escapes the detector. However, a variety of new physics models predict particles that decay inside the detector at a discernible distance from the interaction point. Such long-lived particles would create spectacular signatures that evade many prompt searches. This talk will present recent CMS searches for new long-lived particles using Run 2 data. This talk will also highlight the experimental challenges that these signatures pose for the trigger, offline reconstruction, and non-standard backgrounds.

Recent Progress in ML for Tracker DQM

Author: Guillermo Antonio Fidalgo Rodriguez¹

¹ *University of Puerto Rico at Mayagüez*

Corresponding Author: guillermo.fidalgo@cern.ch

Data Quality Monitoring (DQM) is an important process of collecting high quality data for physics analysis. Currently, the workflow of DQM is manpower intensive to scrutinize and certify hundreds of histograms. Identifying good quality and reliable data is necessary to make accurate predictions, simulations, therefore anomalies in the detector must be timely identified to minimize data loss. With the use of Machine Learning (ML) algorithms raising alarms at the anomalies or failures can be automated and data certification process be made more efficient. The Tracker DQM team at the CMS Experiment (at the LHC) has been working on designing and implementing ML features to monitor this complex detector. This contribution presents the recent progress in this direction.

Model Validation and Extraction of the Inclusive Muon Neutrino Charged Current Cross Section at MicroBooNE

Author: Wenqiang Gu¹

¹ *Brookhaven National Laboratory (US)*

Corresponding Author: wenqiang.gu@cern.ch

The MicroBooNE detector has an active mass of 85 tons of liquid argon and is located along the Booster Neutrino Beam (BNB) at Fermilab. It has a rich physics program including the search for a low-energy excess observed at MiniBooNE and measurements of neutrino-Argon interaction cross sections. In this talk, we present a procedure, using the Wiener-SVD unfolding method, to extract the nominal neutrino flux-averaged total and differential cross sections of the inclusive muon neutrino charged-current interaction on argon. This procedure relies on a minimal set of assumptions while maximizing the power in comparing data results with predictions from theory and event generators. Taking advantage of the power of a Liquid Argon Time Projection Chamber (LArTPC) and the Wire-Cell tomographic event reconstruction paradigm, this procedure enables a new round of cross section measurements at MicroBooNE.

Application of Quantum Machine Learning using the Quantum Kernel Algorithm on High Energy Physics Analysis at the LHC

Authors: Shaojun Sun¹; Sau Lan Wu¹

¹ *University of Wisconsin Madison (US)*

Corresponding Author: shaojun.sun@cern.ch

Quantum machine learning could possibly become a valuable alternative to classical machine learning for applications in High Energy Physics by offering computational speed-ups. In this study, we employ a support vector machine with a quantum kernel estimator (QSVM-Kernel method) to a recent LHC flagship physics analysis: $t\bar{t}H$ (Higgs boson production in association with a top quark pair). In our quantum simulation study using up to 20 qubits and up to 50000 events, the QSVM-Kernel method performs as well as its classical counterparts in three different platforms from Google Tensorflow Quantum, IBM Quantum and Amazon Braket. Additionally, using 15 qubits and 100 events, the application of the QSVM-Kernel method on the IBM superconducting quantum hardware approaches the performance of a noiseless quantum simulator. Our study confirms that the QSVM-Kernel method can use the large dimensionality of the quantum Hilbert space to replace the classical feature space.

Track-Based Triggers for Long-Lived Particles at Future Colliders

Authors: Jesse Nicole Farr¹; Tova Ray Holmes¹

¹ *University of Tennessee (US)*

Corresponding Author: jfarr7@vols.utk.edu

Originally, the Large Hadron Collider (LHC) was designed to complete the Standard Model (SM) of particle physics, and while great progress has been made in validating the SM, it still leaves unexplained phenomena. Because of this, it is useful to implement the search for Beyond the Standard Model (BSM) physics. The high luminosity upgrade to the LHC (HL-LHC) can improve current searches for BSM physics by utilizing hardware and track triggering systems optimized for long-lived particles (LLPs) and exotic signatures indicative of new physics. The design of the hardware and the track triggering algorithms necessary in the search for BSM physics should have a high efficiency (reduce background and reduce number of events lost) and be computationally affordable (fast algorithms). This talk addresses the triggering parameters needed to cover a large range of LLP signatures and exotic models, specifically displaced leptons.

Measurements of the top quark pair production in 5.02 TeV pp and PbPb collisions

Author: Luis Fernando Alcerro Alcerro (On behalf of the CMS Collaboration)¹

¹ *The University of Kansas (US)*

Corresponding Author: l.alcerro@cern.ch

The top quark pair production cross-section is measured in proton-proton and lead-lead collisions at a center-of-mass energy of 5.02 TeV. The data, collected in 2017 and 2018 by the CMS experiment at the LHC, correspond to a proton-equivalent integrated luminosity of 304 and 78 pb⁻¹, respectively. The measurements are performed using events with one electron and one muon of opposite sign, and at least two jets. The measured cross-sections are found to be consistent with each other as well as perturbative QCD calculations, including state-of-the-art free- or bound-nucleon parton distribution functions. They constitute the first step towards using the top quark as a novel tool to probe the quark-gluon plasma, an exotic state of strongly interacting quantum chromodynamics matter which is routinely produced in ultrarelativistic heavy nuclei collisions.

Corresponding Author: yjzheng218@gmail.com

Measurements of the di-leptonic top-antitop events at the LHC unraveled several important excesses. We examine the possibility that those excesses are consequences of the lack of non-perturbative enhancement of the production cross section near the t - t bar threshold. While sub-dominant in terms of total rates, so-far neglected toponium effects yield the additional production of di-leptonic systems of small invariant mass and small azimuthal angle separation, which could contribute the above-mentioned deviations from the Standard Model. We propose a method to discover toponium in present and future data, and our results should pave the way to further experimental and phenomenological studies on toponium. Deeper understanding of the threshold behavior of the top pair production is necessary to accurately determine the top quark mass, which is one of the most important parameters of the SM.

The High Luminosity upgrade of Large Hadron Collider (HL-LHC) will increase the LHC Luminosity by an order of magnitude increasing with it the density of particles on the detector by an order of magnitude. For protecting the inner detectors of experiments and for monitoring the delivered luminosity, a radiation hard beam monitor is being developed. For ATLAS we are developing a set of detectors based on poly-crystalline Chemical Vapor Deposition (pCVD) diamonds and a dedicated rad-hard ASIC. Due to the large range of particle flux through the detector, flexibility is very important. To satisfy the constraints imposed by the HL-LHC, our solution is based on segmenting each single diamond sensor into multiple devices of varying size and reading them out with a new multichannel readout chip. In this talk we describe the proposed system design including detectors, electronics, mechanics and services and present preliminary results from the prototype ASIC and first devices fabricated using the ASIC.

Lepton Flavor and Precision Measurements / 70**Machine Learning for Background Hit Rejection in the Mu2e Straw Tracker****Author:** Digvijay Roy Varier¹**Co-author:** Richard Bonventre²¹ *University of California, Berkeley*² *Lawrence Berkeley National Lab*

Corresponding Author: digvijay.roy.varier@cern.ch

The Mu2e experiment at Fermilab will search for charged lepton flavor violation (CLFV) via muon to electron conversion, with a goal of improving the previous upper limit by four orders of magnitude and reaching unprecedented single-event sensitivities. The signal of CLFV conversion is a ~ 105 MeV electron, which is detected using a high-precision straw tracker. Protons produced by muon capture in the stopping target can create highly ionizing straw hits, and these hits constitute a background that can impact reconstruction efficiency. In this talk, I will discuss improving the rejection of this background by replacing a simple cut on the energy deposited in the straw with a TMVA-based machine learning algorithm. In particular, it is found that a neural network using the ADC waveform shape and Time-Over-Threshold significantly improves both the signal electron acceptance and proton rejection efficiency.

Dark Energy Spectroscopic Instrument: Science Overview

Author: Andreu Font-Ribera¹

¹ *Institut de Física d'Altes Energies (IFAE)*

Corresponding Author: afont@ifae.es

Some of the open questions in fundamental physics can be addressed by looking at the distribution of matter in the Universe as a function of scale and time (or redshift). We can study the nature of dark energy, causing the accelerated expansion of the Universe. We can measure the sum of the neutrino masses, and potentially determine their hierarchy. We can test the standard model at energies higher than those accessible at the laboratory, by studying the primordial density perturbations. The Dark Energy Spectroscopic Instrument (DESI) has just started a 5-years program to generate the largest and most accurate 3D map of the distribution of galaxies and quasars. By measuring the statistical properties of these catalogs, DESI will be able to reconstruct the expansion history of the Universe over the last 11 billion years, while making precise measurements of the growth of structure. In this presentation, I will review the forecasted performance of the DESI survey, and show how it will dramatically improve our understanding of dark energy, inflation, and the mass of the neutrinos.

ECAL trigger primitives performance in Run 2 and improvements for Run 3

Author: Davide Valsecchi¹

¹ *Università degli Studi e INFN Milano-Bicocca (IT)*

Corresponding Author: davide.valsecchi@cern.ch

The CMS electromagnetic calorimeter (ECAL) is a high resolution crystal calorimeter operating at the CERN LHC. The on-detector readout electronics digitizes the signals and provides information on the deposited energy in the ECAL to the hardware-based Level-1 trigger system. The L1 trigger system receives information from different CMS subdetectors at 40 MHz, the proton bunch collision rate, and decides for each collision whether the full detector must be read out, reducing the rate of accepted events to about 100 kHz. The increased luminosity of the LHC Run2 with respect to Run1 has required frequent calibrations during data taking operations to account at trigger level for radiation-induced changes in crystal and photodetector response. For the LHC Run3 (2022-24), further improvements in the energy and time reconstruction of the CMS ECAL trigger primitives are being explored. These exploit additional features of the on-detector electronics. In this presentation we will review the ECAL trigger primitives performance during LHC Run2 and present the improvements to the ECAL trigger system envisaged for the LHC Run3.

Variable Importance Ranking in the CMS Search for pp to ttt in the Single Lepton Final State at a Center-of-Mass Energy of 13 TeV

Author: Daniel Li¹

Co-authors: Meenakshi Narain ²; Emanuele Usai ²; Sinan Sagir ³

¹ *Brown University (US)*

² *Brown University*

³ *Karamanoglu Mehmetbey Universitesi*

Corresponding Author: daniel.sunyou.li@cern.ch

Variable Importance is a variable ranking framework that uses machine learning methods, such as neural networks, to construct a quantitative metric for characterizing a variable's discriminatory power in binary classification problems. The Variable Importance framework is presented in the context of the CMS search for the rare Standard Model process of three top quark production to the single lepton final state. The importance metrics for a set of 76 multivariate variables describing a 13 TeV proton-proton collision are determined, and a neural network discriminator is trained for a subset of the ranked variables which will be used in a likelihood analysis. The Variable Importance framework includes hyper parameter optimization and k-fold cross validation training when constructing the final discriminator. Preliminary results for the expected three top signal and cross section using 101 fb^{-1} of simulated Monte Carlo samples using the Run 2 CMS detector is shown. Additionally, a study on Variable Importance's predictive power of the expected significance using a cumulative importance metric is shown to further validate the accuracy of Variable Importance's quantitative ranking.

The Earth as a transducer for dark-photon dark-matter detection

Author: Saarik Kalia¹

Co-authors: Derek Jackson Kimball²; Michael Fedderke³; Peter Graham¹

¹ *Stanford University*

² *California State University, East Bay*

³ *Johns Hopkins University*

Corresponding Author: saarik@stanford.edu

In this talk, I will propose the use of the Earth as a transducer for ultralight dark-matter detection. In particular I will point out a novel signal of kinetically mixed dark-photon dark matter: a monochromatic oscillating magnetic field generated at the surface of the Earth. Similar to the signal in a laboratory experiment in a shielded box (or cavity), this signal arises because the lower atmosphere is a low-conductivity air gap sandwiched between the highly conductive interior of the Earth below and ionosphere or interplanetary medium above. At low masses (frequencies) the signal in a laboratory detector is usually suppressed by the size of the detector multiplied by the dark-matter mass. Crucially, in our case the suppression is by the radius of the Earth, and not by the (much smaller) height of the atmosphere. The magnetic field signal exhibits a global vectorial pattern that is spatially coherent across the Earth, which enables sensitive searches for this signal using unshielded magnetometers dispersed over the surface of the Earth. I will summarize the results of such a search using a publicly available dataset from the SuperMAG collaboration. The constraints from this search are complementary to existing astrophysical bounds. Future searches for this signal may improve the sensitivity over a wide range of ultralight dark-matter candidates and masses.

Warming Up Cold Inflation

Author: Saarik Kalia¹

Co-authors: Peter Graham¹; William DeRocco¹

¹ *Stanford University*

Corresponding Author: saarik@stanford.edu

The axion is a well-motivated candidate for the inflaton, as the radiative corrections that spoil many single-field models are avoided by virtue of its shift symmetry. However, axions generically couple to gauge sectors. As the axion rolls through its potential, this coupling can result in the production of a co-evolving thermal bath, a situation known as “warm inflation.” Inflationary dynamics in this warm regime can be dramatically altered and result in significantly different observable predictions. In this talk, I will show that for large regions of parameter space, axion inflation models once assumed to be safely “cold” are in fact warm, and must be reevaluated in this context.

Magnetic charge and Massive Photon

Author: Michael Dunia¹

Co-authors: Douglas Singleton¹; Timothy Evans¹

¹ *California State University, Fresno*

Corresponding Author: michaelrobertdunia@mail.fresnostate.edu

In this talk, we correct previous work on magnetic charge plus a photon mass. We show that contrary to previous claims this system has a very simple, closed form solution which is the Dirac string potential multiplied by a exponential decaying part. Interesting features of this solution are discussed namely: (i) the Dirac string becomes a real feature of the solution; (ii) the breaking of gauge symmetry via the photon mass leads to a breaking of the rotational symmetry of the monopole's magnetic field; (iii) the Dirac quantization condition is potentially altered.

Dark Matter / 81**Self-interacting Dark Matter with Scalar Dilepton Mediator****Author:** Chung Kao¹¹ *University of Oklahoma***Corresponding Author:** kao@physics.ou.edu

The cold dark matter (CDM) candidate with weakly interacting massive particles can successfully explain the observed dark matter relic density in cosmic scale and the large-scale structure of the Universe. However, a number of observations at the satellite galaxy scale seem to be inconsistent with CDM simulation.

This is known as the small-scale problem of CDM.

In recent years, it has been demonstrated that self-interacting dark matter (SIDM) with a light mediator offers a reasonable explanation for the small-scale problem.

We adopt a simple model with SIDM and focus on the effects of Sommerfeld enhancement.

In this model, the dark matter candidate is a leptonic scalar particle with a light mediator.

We have found favored regions of the parameter space with proper masses and coupling strength generating a relic density that is consistent with the observed CDM relic density.

Furthermore, this model satisfies the constraints of recent direct searches and indirect detection for dark matter as well as the effective number of neutrinos and the observed small-scale structure of the Universe.

In addition, this model with the favored parameters can resolve the discrepancies between astrophysical observations and N -body simulations.

Top Quark / 82**Flavor changing top decays to charm and Higgs with $\tau\tau$ at the LHC****Author:** Chung Kao¹¹ *University of Oklahoma***Corresponding Author:** kao@physics.ou.edu

We investigate the prospects of discovering the top quark decay into a charm quark and a Higgs boson ($t \rightarrow ch^0$) in top quark pair production at the CERN Large Hadron Collider (LHC).

A general two Higgs doublet model is adopted to study flavor changing neutral Higgs (FCNH) interactions.

We perform a parton level analysis as well as Monte Carlo simulations using `\textsc{Pythia}`⁸ and `\textsc{Delphes}` to study the flavor changing top quark decay

$t \rightarrow ch^0$, followed by the Higgs decaying into $\tau^+\tau^-$, with the other top quark decaying to a bottom quark (b) and two light jets ($t \rightarrow bW \rightarrow bj\bar{j}$).

To reduce the physics background to the Higgs signal, only the leptonic decays of tau leptons are considered, $\tau^+\tau^- \rightarrow e^\pm\mu^\mp + \text{MET}$,

where MET represents the missing transverse energy from the neutrinos.

In order to reconstruct the Higgs boson and top quark masses as well as to reduce the physics background, the collinear approximation for the highly boosted tau decays is employed.

Furthermore, the energy distribution of the charm quark helps set the acceptance criteria used to reduce the background and improve the statistical significance of the signal.

We study the discovery potential for the FCNH top decay at the LHC with collider energy $\sqrt{s} = 13$ and 14 TeV as well as a future hadron collider with $\sqrt{s} = 27$ TeV.

Our analysis suggests that a high energy LHC at $\sqrt{s} = 27$ TeV will be able to discover this FCNH signal with an integrated luminosity $\mathcal{L} = 3 \text{ ab}^{-1}$ for a branching fraction

$\text{calB}(t \rightarrow ch^0) > 1.4 \times 10^{-4}$,

which corresponds to a FCNH coupling $|\lambda_{tch}| > 0.023$.

This FCNH coupling is significantly below the current ATLAS combined upper limit of $|\lambda_{tch}| = 0.064$.

A tri-muon trigger for pair-production of dark photons with the CMS Experiment at the HL-LHC

Author: Paul Edmund Karchin¹

Co-authors: Peter Dong²; Leonard Spiegel³

¹ Wayne State University (US)

² Fermi National Accelerator Lab. (US)

³ FNAL

Corresponding Author: paul.edmund.karchin@cern.ch

Pair production of dark photons is predicted from models of supersymmetry. When both dark photons decay into muon pairs, a trigger selection with three muons can be highly efficient for GeV-scale dark photons. We report the results of a simulation study of the CMS detector for p-p collisions at 14 GeV with average pile-up (interactions per bunch crossing) of 200. In this study, the dark photons have mass 1 GeV and they are promptly produced (originating from the primary vertex). Efficiency of 90% is obtained for events when the muon with the third largest pT is in the range 5-10 GeV. Efficiency approaches 100% when the third largest muon pT exceeds 40 GeV. The tri-muon trigger provides large increases in efficiency over single and double muon triggers for third largest muon with pT in the range 5 GeV to 40 GeV.

¹ NA

Corresponding Author: risp.kitazawa@nifty.com

Possible structural linkage between neutrinos and charged leptons under neutrino mixing of being in neutrinos' own maximum contact is studied. Where it is provided that one neutrino (fermion) and neutrino-pair (boson) may interact. So it should have such a restrained condition that one neutrino makes a maximum contact number-6 (six) with other 6 neutrinos under 2D mixing. Then possible structural linkage between neutrinos and charged leptons will emerge vertically, and it seems common and recurrent in their three generations. There, the winding angles of series of the neutrino-pair, with which higher charged leptons (μ , τ) possibly build up, appear to fall almost on observed neutrino mixing angles of θ_{12} and θ_{23} , respectively.

Space-Time Conjunction

Author: Bruce Toy^{None}

Corresponding Author: bruce toy@verizon.net

Rather than view time as one of four dimensions in space-time, we start with the assumption that time is best described in a three dimensional domain of its own, defined by spherical coordinates, and is "linked to" the spatial domain, defined by orthogonal Cartesian coordinates. The result is a six-dimensional structure that is simple to visualize and define geometrically. We will refer to it as Space-Time Conjunction, as opposed to the more common term -Space-Time Continuum.

The spatial domain is the structure of mass and the time domain is the structure of energy. In theory they can exist separately but whenever energy is associated with mass the two domains are functionally joined -Space-Time Conjunction.

Transitions between the two domains occur in accordance with the laws of physics and several paradoxes can be understood. One in particular is the behavior of electrons. Under non-stressed conditions electrons can be described by Schrodinger functions in the spatial domain but when the stress of an electric field is applied they transition to the time domain until the stress is removed.

Relativistic behavior can be properly analyzed, but only if we recognize that the term "reference frame" is not accurate. It cannot mathematically exist as a three-dimensional concept. Reference can only refer to a single point, which represents the common point of origin of a unique conjunction of a spatial domain reference and time domain reference, in order to serve this purpose. The consequence is that we must then use "reference points" to analyze relativistic motion. Relativity paradoxes vanish as if by magic.

Besides the six-dimensional structure, one, and only one, empirical assumption is included in this model. Previously, electric charge has been defined only by the measurement of the force it exerts. That does not quite define the basic nature of electric charge. We can remedy that problem if we modify one constraint traditionally placed on solutions to Schrodinger's equations.

We are removing the conventional constraint that the Schrodinger wave function must establish

continuity across the particle boundary by reducing to zero magnitude at that boundary.

Instead, we assume or postulate a single-magnitude, discrete, wave function magnitude at the particle boundary. Mathematically speaking the wave function changes its form but still satisfies the continuity requirement. It simply transitions to an evanescent wave function outside the boundary of the particle.

We can refer to this as a time discontinuity that, by nature of exponential decay of the evanescent wave, exists in a small fringe region about the particle. If we establish this discontinuity in the wave function at multiple of one-third pi, we produce single-valued positive and negative charge. By consequence, it also incorporates the definition of spin. It is also compatible with the quark structure of particle physics.

In summary, we may now have a physical definition of electric charge. Furthermore, we show that analyses using this space-time geometry and the definition of charge even allow us to characterize magnetic and nuclear binding forces into a unified theory.

Measurement of the properties of Higgs boson production at $\sqrt{s} = 13$ TeV in the diphoton decay channel using 139 fb^{-1} of pp collision data with the ATLAS experiment

Author: Chen Zhou¹

¹ University of Wisconsin Madison (US)

Corresponding Author: chen.zhou@cern.ch

Measurements of Higgs boson production cross sections are carried out in the diphoton decay channel using 139 fb^{-1} of pp collision data at $\sqrt{s} = 13$ TeV collected by the ATLAS experiment. Cross-sections for gluon fusion, weak vector boson fusion, associated production with a W or Z boson, and top quark associated production processes are reported. An upper limit of eight times the Standard Model prediction is set for the associated production of a Higgs boson with a single top quark process. Higgs boson production is further characterized through measurements of the Simplified Template Cross-Sections (STXS) in 27 fiducial regions. All the measurement results are compatible with the Standard Model predictions.

Search for resonant pair production of Higgs bosons in the $bb\bar{b}\bar{b}$ final state using 139 fb^{-1} of $\sqrt{s} = 13$ TeV pp collision data with the ATLAS detector

Author: Rui Zhang¹

¹ University of Wisconsin Madison (US)

Corresponding Author: rui.zhang@cern.ch

A search for resonant Higgs boson pair production in the four b-jet final state is conducted. The analysis uses 36 fb^{-1} of pp collision data at $\sqrt{s} = 13 \text{ TeV}$ collected with the ATLAS detector. The analysis is divided into two regimes, targeting Higgs boson decays which are reconstructed as pairs of b-tagged small-radius jets or as single large-radius jets associated with b-tagged track-jets. Spin-0 and spin-2 benchmark signal models are considered, both of which correspond to resonant HH production via gluon–gluon fusion and decaying to two Standard Model Higgs bosons. No significant evidence for a signal is observed. Upper limits are set on the production cross-section times branching ratio to Higgs boson pairs of a new resonance in the mass range from 251 GeV to 3 TeV.

Improvements to ATLAS Inner Detector Track reconstruction for LHC Run-3

Author: Maximilian Emanuel Goblirsch-Kolb¹

¹ *Brandeis University (US)*

Corresponding Author: maximilian.goblirsch-kolb@cern.ch

Reconstruction of charged particle trajectories (tracks) in the tracking detector surrounding the interaction region is a key component of the event reconstruction in the ATLAS experiment at the Large Hadron Collider.

The ATLAS Inner Detector (ID) records up to 1500 individual signals (hits) per proton-proton collision, and between 20 and 60 collisions happen simultaneously at each bunch crossing.

As a result, about 30000 to 90000 individual hits need to be combined into track candidates.

This represents a significant combinatorial challenge, and track reconstruction was by far the largest single user of processing time in the reconstruction of the LHC Run 2 data.

In preparation for LHC Run 3, the ATLAS collaboration undertook a major effort to optimize and speed up the track reconstruction for the coming data-taking campaign.

This talk will summarize track reconstruction strategy in ATLAS, outline the improvements that were made and show their impact on the computational and physics performance.

If time permits, an outlook to track reconstruction with the new ITk tracking detector to be installed for the High-Luminosity LHC campaign can be given.

Framework for Hyperparameter Optimization in Machine Learning using the ATLAS Grid Computing Resource

Author: Alkaid Cheng¹

¹ *University of Wisconsin Madison (US)*

Corresponding Author: chi.lung.cheng@cern.ch

Application of machine learning methods in high energy physics has received tremendous success in recent years with rapidly growing use cases. A key aspect in improving the performance of a given machine learning model has been the optimization of its hyperparameters which is usually computationally expensive. A framework has been developed to provide a high-level interface for automatic hyperparameter optimization that utilizes the ATLAS grid computing resource with hardware acceleration from GPU machines. The framework is equipped with a wide variety of hyperparameter optimization algorithms, distributed optimization schemes, intelligent job scheduling strategy based on available resources, flexible hyperparameter configuration space generation, and adaptation to the ATLAS intelligent Data Delivery Service. An example use case for the hyperparameter optimization of a Boosted Decision Tree model in the $HH \rightarrow bb\gamma\gamma$ non-resonant analysis in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector is also presented.

Drell-Yan angular lepton distributions at small x from TMD factorization

Author: Ian Balitsky¹

¹ JLab/ODU

Corresponding Author: balitsky@jlab.org

The Drell-Yan process is studied in the framework of TMD factorization in the Sudakov region $s \gg Q^2 \gg q_{\perp}^2$ corresponding to recent LHC experiments with Q^2 of order of mass of Z-boson and transverse momentum of DY pair \sim few tens GeV. The DY hadronic tensors are expressed in terms of quark and quark-gluon TMDs with $\frac{1}{Q^2}$ and $\frac{1}{N_c^2}$ accuracy. It is demonstrated that in the leading order in N_c the higher-twist quark-quark-gluon TMDs reduce to leading-twist TMDs due to QCD equation of motion. The resulting hadronic tensors depend on two leading-twist TMDs: f_1 responsible for total DY cross section, and Boer-Mulders function h_1^{\perp} . The corresponding qualitative and semi-quantitative predictions seem to agree with LHC data on five angular coefficients $A_0 - A_4$ of DY pair production. The remaining three coefficients $A_5 - A_7$ are determined by quark-quark-gluon TMDs multiplied by extra $\frac{1}{N_c}$ so they appear to be relatively small in accordance with LHC results.

Reconstructing silicon pixel hits using neural networks

Authors: Sanjana Sekhar¹; Oz Amram¹; Petar Maksimovic¹; Tamas Almos Vami¹; Morris Swartz¹

¹ *Johns Hopkins University (US)*

Corresponding Author: sanjana.sekhar@cern.ch

Future operation of the LHC and HL-LHC will record a higher number of proton-proton collisions and therefore yield larger data rates and sample sizes. This will further stress real-time triggering systems and offline event reconstruction. Therefore, heterogenous computing systems utilizing both CPU and GPU hardware are being developed at CMS to deal with these tasks. Specifically, the precise reconstruction of silicon pixel hits is an important aspect of tracking at the HLT and offline. However current reconstruction algorithms - the generic and template algorithms - are not optimal for a GPU implementation. In recent years, fast implementations of neural networks have been built on GPU hardware for deep learning. Additionally, neural networks have shown promising results in various ATLAS and CMS tasks over the last few years. We therefore investigate the use of hybrid convolutional neural networks and deep neural networks in local hit reconstruction. We train and test the networks on data from a detailed silicon sensor simulation, Pixelav, tuned to simulate all sensors, including heavily radiation-damaged detectors. We find that the resulting reconstruction algorithms equals, if not outperforms present reconstruction algorithms in the predicted resolutions.

Search for the Higgs boson decaying to a pair of muons in pp collisions at 13 TeV with the ATLAS detector

Author: Jay Chan¹

¹ *University of Wisconsin Madison (US)*

Corresponding Author: jay.chan@cern.ch

The dimuon decay of the Higgs boson is the most promising process for probing the Yukawa couplings to the second generation fermions at the Large Hadron Collider (LHC). We present a search for this important process using the data corresponding to an integrated luminosity of 139 fb^{-1} collected with the ATLAS detector in pp collisions at $\sqrt{s} = 13 \text{ TeV}$ at the LHC. Events are divided into several regions using boosted decision trees to target different production modes of the Higgs boson. The measured signal strength (defined as the ratio of the observed signal yield to the one expected in the Standard Model) is $\mu = 1.2 \pm 0.6$. The observed (expected) significance over the background-only hypothesis for a Higgs boson with a mass of 125.09 GeV is 2.0σ (1.7σ).

Electroweak Restoration at the LHC and Beyond

Authors: Ian Lewis¹; Li Huang²; Samuel Lane²; Zhen Liu³

¹ *The University of Kansas*

² *University of Kansas*

³ *University of Minnesota*

Corresponding Author: samuel.lane@ku.edu

The LHC is exploring electroweak (EW) physics at the scale EW symmetry is broken. As the LHC and new high energy colliders push our understanding of the Standard Model to ever-higher energies, it will be possible to probe not only the breaking of but also the restoration of EW symmetry. We propose to observe EW restoration in double EW boson production via the convergence of the Goldstone boson equivalence theorem. We measure this convergence through the ratio of differential cross sections for VH production. We present a method to extract this ratio from collider data. With a full signal and background analysis, we demonstrate that the 14 TeV HL-LHC can confirm that this ratio converges to one to 40% precision while at the 27 TeV HE-LHC the precision will be 6%. We also investigate statistical tests to quantify the convergence at high energies. Our analysis provides a roadmap for how to stress test the Goldstone boson equivalence theorem and our understanding of spontaneously broken symmetries, in addition to confirming the restoration of EW symmetry.

The calculation of inelastic neutrino-nucleus scattering

Author: Wei-Chih Huang¹

¹ *Physics Department, Texas A&M University*

Corresponding Author: s104021230@tamu.edu

We study inelastic neutrino-nucleus scattering. Primarily we target ^{40}Ar , ^{133}Cs , and ^{127}I nuclei. Nuclear shell model provides clear understanding of nuclei. In practice we use Bigstick, which is based on nuclear shell model, to generate the numerical results of the nuclear structure. We also include spin-independent and spin-dependent neutrino-nucleus currents based on chiral effective field theory (EFT) in our calculation. Hence the scattering amplitude then can be expressed as the linear combination of the nuclear response functions given by chiral EFT. In the study there are two scattering processes we have considered, charged lepton-nucleus ($\nu + N \rightarrow l^- + N^*$) and neutrino-nucleus ($\nu + N \rightarrow \nu + N^*$). We predict the number of photon production cross-sections from the inelastic scattering. We also calculate the light dark matter-nucleus inelastic scattering cross-section and the event rate.

Dark Energy Spectroscopic Instrument: Instrumentation Overview

Author: Paul Martini¹

¹ *Ohio State University*

Corresponding Author: martini.10@osu.edu

The Dark Energy Spectroscopic Instrument (DESI) has embarked on an ambitious survey to explore the nature of dark energy with spectroscopic measurements of 35 million galaxies and quasars in just five years. DESI will determine precise redshifts and employ the Baryon Acoustic Oscillation method to measure distances from the local universe to beyond 11 billion light years, as well as employ Redshift Space Distortions to measure the growth of structure and probe potential modifications to general relativity. In this presentation I will describe the instrumentation we developed to conduct the DESI survey, as well as the flowdown from the science requirements to the technical requirements on the instrumentation. The new instrumentation includes a wide-field, 3.2 degree diameter prime-focus corrector that focuses the light onto 5020 robotic fiber positioners on the 0.8-m diameter, aspheric focal surface. This high density is only possible because of the very compact positioner design, which allows a minimum separation of only 10.4-mm. The positioners and their fibers are evenly divided among ten wedge-shaped petals, and each bundle directs the light of 500 fibers into one of ten spectrographs via a contiguous, high-efficiency, nearly 50-m fiber cable bundle. The ten, identical spectrographs each use a pair of dichroics to split the light into three wavelength channels, and each channel is optimized for a distinct wavelength and spectral resolution that together record the light from 360-980 nm. I will conclude with some highlights from the on-sky validation of the instrument.

Exploring color-octet scalar parameter space in minimal R-symmetric models

Authors: Linda Carpenter¹; Matthew Smylie¹; Taylor Murphy¹

¹ *Ohio State University*

Corresponding Author: smylie.8@osu.edu

In this work we study the collider phenomenology of color-octet scalars (sgluons) in minimal supersymmetric models endowed with a global continuous R symmetry. We systematically catalog the significant decay channels of scalar and pseudoscalar sgluons and identify novel features that are natural in these models. These include decays in nonstandard diboson channels, such as to a gluon and a photon; three-body decays with considerable branching fractions; and long-lived particles with displaced vertex signatures. We also discuss the single and pair production of these particles and show that they can evade existing constraints from the Large Hadron Collider, to varying extents, in large regions of reasonable parameter space. We find, for instance, that a 725 GeV scalar and a 350 GeV or lighter pseudoscalar can still be accommodated in realistic scenarios.

SM Extension with Anomaly Free Flavor U(1)

Author: Zurab Tavartkiladze¹

¹ *Ilia State University*

Corresponding Author: zurab.tavartkiladze@gmail.com

Although being very successful, the Standard Models (SM) of particle physics, fails to explain some observations and also puzzles. In particular, neutrino data can't be accommodated within the SM. Also, the origin of observed hierarchies between charged fermion masses and CKM matrix elements remain unexplained within the SM.

We consider simple extension by non-anomalous U(1) flavor symmetry, which gives natural explanation of fermion flavor and, including the right handed neutrinos, gives successful (and very specific) neutrino oscillation scenario.

Other interesting properties and phenomenological implications, of the proposed model, will be also discussed.

Calibration of the light flavour mistag rate for ATLAS *b*-jet identification algorithms using the negative tag method in *pp* collisions at $\sqrt{s} = 13$ TeV

Author: Angela Maria Burger¹

¹ *Oklahoma State University (US)*

Corresponding Author: angela.maria.burger@cern.ch

Many analyses in ATLAS rely on the identification of jets containing b -hadrons (b -jets) with high efficiency while rejecting more than 99% of non- b -jets. Identification algorithms, called b -taggers, exploit b -hadron properties such as their long lifetime, their high mass, and high decay multiplicity. Recently developed ATLAS b -taggers using neural networks are expected to outperform previous b -taggers by a factor of two in terms of light jet rejection. Nevertheless, contributions from light jet mistags can be non-negligible in certain analyses phase spaces. It is therefore important to precisely measure the mistag rate of the light jets in both data and simulation to correct the corresponding rate in simulation.

Due to the high light jet rejection of the b -taggers, the mistag rate cannot be measured directly but rather by means of a modified tagger, designed to decrease the b -jet efficiency while leaving the light jet response unchanged. This so-called “negative tag method” has been improved recently: uncertainties are reduced by constraining non-light flavour contributions with a data-driven method and the dominant systematic uncertainty has been reduced significantly, from 10-60% to 5-20% due to improved inner detector modeling and an auxiliary analysis. The method and a selection of results released recently to the ATLAS collaboration using pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector will be presented.

Search for non-resonant di-Higgs production in the $HH \rightarrow b\bar{b}\gamma\gamma$ decay channel in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

Author: Alex Zeng Wang¹

Co-author: Sau Lan Wu¹

¹ University of Wisconsin Madison (US)

Corresponding Author: awang89@wisc.edu

We present a search for non-resonant di-Higgs production in the $HH \rightarrow b\bar{b}\gamma\gamma$ decay channel. The measurement uses 139 fb^{-1} of pp collisions recorded by the ATLAS experiment at a center-of-mass energy of 13 TeV. Selected events are separated into multiple regions, targeting both the Standard Model (SM) signal and Beyond Standard Model (BSM) signals with modified Higgs self-couplings. Further details on the optimization of the event selection are highlighted. No excess with respect to background expectations are found and upper limits at 95% confidence level are set on the di-Higgs production cross sections. The observed (expected) limit on the Standard Model cross section is 130 fb (180 fb), corresponding to 4.1 (5.5) times the predicted value. The observed (expected) Higgs trilinear coupling modifier is constrained to be between [-1.5, 6.7] ([2.4, 7.7]).

Electroweak Symmetry Non-restoration in UV-complete Models with New Fermions

Author: Yu Hang Ng¹

Co-author: Peisi Huang¹

¹ *University of Nebraska-Lincoln*

Corresponding Author: yu-hang.ng@huskers.unl.edu

In certain extensions of the Standard Model(SM), the interactions between the new scalars and the SM Higgs can cause the electroweak(EW) symmetry to remain broken at temperatures well above the electroweak scale. Fermionic-induced EW symmetry non-restoration (EWSNR) effect has also been studied in the context of effective field theories, where EWSNR is linked to some non-renormalizable interactions; thus, fermionic-induced EWSNR only occurs below specific cutoff temperature. In this talk, I will introduce some UV-complete models with new fermions that have unbroken EW symmetry at high temperatures. In these models, fermionic-induced EWSNR is not limited by a cutoff temperature because some of the heavy fermions are always decoupled from thermal equilibrium at high temperatures as a consequence of their mass mechanisms. Then, I will identify the parameter space that satisfies the theoretical (stability of effective potential, perturbative unitarity bound, thermal equilibrium conditions) and experimental constraints. Within this parameter space, I will examine the novel thermal histories of these models and their phenomenological implications.

Corresponding Author: chen2954@purdue.edu

The Mu2e experiment will search for Beyond-the-Standard-Model, Charged Lepton Flavor Violation (CLFV) in muon capture $\mu^- + \text{Al} \rightarrow e^- + \text{Al}$, with a single event sensitivity surpassing the current world's best limit by 10,000 times. To report a reliable result, the number of stopped muons will be normalized to 10% precision utilizing a combination of two γ -ray and one x-ray transitions. The first, directly proportional to the CLFV signal is the 1808.7 keV γ -ray emitted promptly in the muon capture process,

The second, is the 346.8 keV x-ray emitted promptly from the $2p \rightarrow 1s$ muonic atomic transition in Al, from muon stops in the target. The third, is the 844 keV γ -ray from the β -decay

where ${}^{27}\text{Mg}$ is produced in the muon capture process, and decays with a lifetime of 9.5 minutes.

The stopped-muon rate measurement will use two complementary photon counting detectors. One of them, the LaBr₃ detector, is capable of high rate operation up to and above 800 kcps, with 0.7 % energy resolution. The other, the HPGe detector is capable of energy resolution of 0.1%, however, its rate capability is limited to an estimated ~ 100 kcps.

A real time sub-picosecond phase correction system.

Authors: Diba Dehmeshki¹; Erich Frahm²; Roger Rusack²; Rohith Saradhy²; Yahya Tousi¹

¹ University of Minnesota

² University of Minnesota (US)

Corresponding Author: rohithsaradhy@gmail.com

The use of precision timing to measure time-of-flight or to distinguish events from the same bunch crossing in collider detectors has become a common feature of many modern experiments. Currently achieving a precision of 30 picoseconds is seen as an attainable goal. To move to a precision close to one picosecond will require further advances in our time measurement technology. One central component of any time measurement is a precisely aligned reference clock distributed to all of the detector elements. When the required precision of the measurement is of the order of a picosecond, environmental changes need to be tracked and corrected for to maintain the the precision of the reference clock. In this talk we will present the design and testing of a system capable of measuring the drift in the clock phase (wander) and correcting for it in real time with sub-picosecond precision. For this we have developed an ASIC, using the TSMC 65nm process, that is capable of adjusting with sub-picosecond precision the phase delay of a digital clock signal, and a simple digital dual mixer time difference (DDMTD) circuit that can be used for measuring wander with sub-picosecond precision. Using this system, we will demonstrate the feasibility of distributing reference clocks, detecting and correcting for changes in the phase delay to a precision of ~ 200 fs.

Neural Empirical Bayes: Source Distribution Estimation and its Applications to Simulation-Based Inference

Authors: Maxime Noel Pierre Vandegar¹; Michael Aaron Kagan¹

¹ *SLAC National Accelerator Laboratory (US)*

Corresponding Author: maxime.vandegar@cern.ch

We examine the problem of unfolding in particle physics, or de-corrupting observed distributions to estimate underlying truth distributions, through the lens of Empirical Bayes and deep generative modeling. The resulting method, Neural Empirical Bayes (NEB), can unfold continuous multi-dimensional distributions, in contrast to traditional approaches that treat unfolding as a discrete linear inverse problem. We exclusively apply our method in the absence of a tractable likelihood function, as is typical in scientific domains relying on computer simulations. Moreover, combining NEB with suitable sampling methods allows posterior inference for individual samples, thus enabling the possibility of reconstruction with uncertainty estimation.

Constraints on Axions from Cosmic Distance Measurements

Authors: Manuel Buen-Abad¹; Jiji Fan¹; Chen Sun²

¹ *Brown University*² *Tel Aviv University***Corresponding Author:** chensun@mail.tau.ac.il

Axion couplings to photons could induce photon-axion conversion in the presence of magnetic fields in the Universe. This conversion could impact various cosmic distance measurements, such as luminosity distances to type Ia supernovae and angular distances to galaxy clusters, in different ways. In this paper we consider different combinations of the most up-to-date distance measurements to constrain the axion-photon coupling. Employing the conservative cell magnetic field model for the magnetic fields in the intergalactic medium (IGM) and ignoring the conversion in the intracluster medium (ICM), we find the upper bounds on axion-photon couplings to be around $5 \times 10^{-12} (\text{nG}/B) \sqrt{\text{Mpc}/s} \text{ GeV}^{-1}$ for axion masses m_a below 10^{-13} eV , where B is the strength of the IGM magnetic field, and s is the comoving size of the magnetic domains. When including the conversion in the ICM, the upper bound is lowered and could reach $5 \times 10^{-13} \text{ GeV}^{-1}$ for $m_a < 5 \times 10^{-12} \text{ eV}$. While this stronger bound depends on the ICM modeling, it is independent of the strength of the IGM magnetic field, for which there is no direct evidence yet. These constraints could be placed on firmer footing with an enhanced understanding and control of the astrophysical uncertainties associated with the IGM and ICM. All the bounds are determined by the shape of the Hubble rate as a function of redshift reconstructable from various distance measurements, and insensitive to today's Hubble rate, of which there is a tension between early and late cosmological measurements.

Explainable AI for ML jet taggers using expert variables and layerwise relevance propagation

Authors: Christine Angela McLean¹; Garvita Agarwal²; Ia Iashvili²; Lauren Meryl Hay¹; Margaret Morris³; Salvatore Rappoccio²; Ulrich Schubert^{None}

¹ *SUNY Buffalo*² *The State University of New York SUNY (US)*³ *University at Buffalo***Corresponding Author:** garvita.agarwal@cern.ch

A framework is presented to extract and understand decision-making information from a deep neural network classifier of jet substructure tagging techniques. The general method studied is to provide expert variables that augment inputs (“eXpert AUGmented” variables, or XAUG variables), then apply layerwise relevance propagation (LRP) to networks that have been provided XAUG variables and those that have not. The XAUG variables are concatenated to the classifier’s intermediate input to the final layer or decision. The results show that XAUG variables can be used to interpret classifier behavior, increase discrimination ability when combined with low-level features, and in some cases capture the behavior of the classifier completely. The LRP technique can be used to find relevant information the network is using, and when combined with the XAUG variables, can be used to rank features, allowing one to find a reduced set of features that capture part of the network performance. These XAUG variables can also be added to low-level networks as a guide to improve performance.

Beyond Standard Model / 110**Searches for new resonances decaying to at least one top quark in pp collisions at a center-of-mass energy of 13 TeV.****Author:** Atanu Pathak¹¹ *Purdue University Northwest (US)***Corresponding Author:** pathakatanu01@gmail.com

Many physics models beyond the Standard Model predict heavy new particles preferentially decaying to at least one top quark. Three searches for a heavy resonance decaying into at least one top quark in pp collision at a center-of-mass energy of 13 TeV at the LHC will be presented in the talk. These searches include: The search for a heavy resonance decaying to a top quark and a W boson in the fully hadronic final state as well as in the lepton+jets final state, and the search for W' bosons decaying to a top and a bottom quark in the all-hadronic final state. The three searches use the data collected by the CMS experiment between 2016 and 2018, corresponding to an integrated luminosity of 137 fb⁻¹. Novel machine learning techniques and reconstruction techniques are used to optimize discrimination of top quarks with high Lorentz boosts, which requires the use of non isolated leptons and jet substructure techniques, as well as allowing for a significant improvement of the analysis sensitivity compared with earlier results. No significant excess of events relative to the expected yield from standard model processes is observed. The most stringent limits to date are obtained from these searches.

Particle Detectors / 111**FASER Commissioning****Author:** Savannah Rose Shively¹¹ *University of California Irvine (US)***Corresponding Author:** savannah.rose.shively@cern.ch

FASER (ForwArd Search ExpeRiment) fills the axial blindspot of other, radially arranged LHC experiments. It is installed 480 meters from the ATLAS interaction point, along the collision axis. FASER will search for dark matter and other new, long-lived particles that may be hidden in the collimated reaction products exiting ATLAS. FASER comprises: a magnetic spectrometer built with ATLAS silicon tracker modules; four LHCb outer ECAL modules; an emulsion neutrino detector; and plastic scintillators for veto, trigger and timing. The experiment is currently in its final commissioning stages. I report on successful preliminary tests of hardware and software performance with cosmic rays on the surface, and after installation in situ. FASER will begin taking pp collision data from the start of LHC Run 3, in 2022.

Higgs & Electroweak Physics / 112**Analysis Optimization of the VBF HWW Measurement at the ATLAS Experiment****Author:** Sagar Addepalli¹¹ *Brandeis University (US)***Corresponding Author:** addepalli.sagar@cern.ch

The precision measurements of the properties of the Higgs boson are among the principal goals of the LHC Run-2 program. This talk reports on the measurements of the fiducial and differential Higgs boson production cross sections via Vector Boson Fusion with a muon, an electron, and two neutrinos from the decay of W bosons, along with the presence of two energetic jets in the final state. The analysis uses pp collision data at a center-of-mass energy of 13 TeV collected with the ATLAS detector between 2015 and 2018 corresponding to an integrated luminosity of 139 fb^{-1} . The optimizations of the selection criteria and the signal extraction methods will be discussed in detail, in particular the use of machine learning techniques for performing a multidimensional fit for extracting the signal and normalizing the simulated backgrounds to data.

Neutrinos / 113**Transformer Networks for NOvA Event Classification****Authors:** Alejandro Yankelevich¹; Alexander Shmakov¹¹ *University of California, Irvine***Corresponding Author:** ayankele@uci.edu

The NOvA experiment uses a convolutional neural network (CNN) that analyzes topological features to determine neutrino flavor. Alternative approaches to flavor identification using machine learning are being investigated with the goal of developing a network trained with both event-level and particle-level images in addition to reconstructed physical variables while maintaining the performance of the CNN. Such a network could be used to analyze the individual prediction importances of these inputs. An original network that uses a combination of transformer and MobileNet CNN blocks will be discussed.

Massive Neutrinos and Dark Sector Cosmology from the High-Redshift Cosmic Web

Author: Graziano Rossi¹

¹ *Sejong University*

Corresponding Author: graziano@sejong.ac.kr

I will present the Sejong Suite, an extensive collection of state-of-the-art high-resolution cosmological hydrodynamical simulations spanning a variety of cosmological and astrophysical parameters, primarily developed for modeling the Lyman-Alpha forest and the high-redshift cosmic web. Adopting a particle-based implementation, we follow the evolution of gas, dark matter (cold and warm), massive neutrinos, and dark radiation, and consider several combinations of box sizes and number of particles. Noticeably, for the first time, we simulate extended mixed scenarios describing the combined effects of warm dark matter, neutrinos, and dark radiation, modeled consistently by taking into account the neutrino mass splitting. Along the way, I will also highlight some new results on cosmological neutrinos and the dark sector focused on the matter and flux statistics.

Progress towards a more sensitive CWoLa hunt with the ATLAS detector

Author: Kees Christian Benkendorfer¹

Co-author: Ben Nachman¹

¹ *Lawrence Berkeley National Lab. (US)*

Corresponding Author: kees.christian.benkendorfer@cern.ch

As the search for physics beyond the Standard Model widens, ‘model-agnostic’ searches, which do not assume any particular model of new physics, are increasing in importance. One promising model-agnostic search strategy is Classification Without Labels (CWoLa), in which a classifier is trained to distinguish events in a signal region from similar events in a sideband region, thereby learning about the presence of signal in the signal region. The CWoLa strategy was recently used in a full search for new physics in dijet events from Run-2 ATLAS data; in this search, only the masses of the two jets were used as classifier inputs. It has since been observed that while CWoLa performs well in such low-dimensional use cases, difficulties arise when adding additional jet features as classifier inputs. In this talk, we will describe ongoing work to combat these problems and extend the sensitivity of a CWoLa search by adding new observables to an ongoing analysis using 139 fb^{-1} of data from pp collisions at $\sqrt{s} = 13 \text{ TeV}$ in the ATLAS detector. In particular, we will discuss the anticipated benefits of adding classifier features, as well as the implementation of a simulation-assisted version of CWoLa which makes the strategy more robust.

Measurement of the CP -violating phase ϕ_S in $B_S^0 \rightarrow J/\psi\phi$ decays in ATLAS at 13 TeV

Author: Easwar Anand Narayanan¹

¹ *University of New Mexico (US)*

Corresponding Author: easwar.anand.narayanan@cern.ch

A measurement of the $B_S^0 \rightarrow J/\psi\phi$ decay parameters using 80 fb^{-1} of integrated luminosity collected with the ATLAS detector from 13 TeV proton-proton collisions at the LHC is presented. The measured parameters include the CP -violating phase ϕ_S , the width difference $\Delta\Gamma_S$ between the B_S^0 meson mass eigenstates and the average decay width Γ_S . The values measured for the physical parameters are combined with those from 19.2 fb^{-1} of 7 TeV and 8 TeV data, leading to the following:

$$\phi_S = -0.087 \pm 0.036 \text{ (stat.)} \pm 0.021 \text{ (syst.) rad}$$

$$\Delta\Gamma_S = 0.0657 \pm 0.0043 \text{ (stat.)} \pm 0.0037 \text{ (syst.) ps}^{-1}$$

$$\Gamma_S = 0.6703 \pm 0.0014 \text{ (stat.)} \pm 0.0018 \text{ (syst.) ps}^{-1}$$

Results for ϕ_S and $\Delta\Gamma_S$ are also presented as 68% confidence level contours in the $\phi_S - \Delta\Gamma_S$ plane. Furthermore, the transversity amplitudes and corresponding strong phases are measured. ϕ_S and $\Delta\Gamma_S$ measurements are in agreement with the Standard Model predictions.

Calibration of q/g Taggers in the ATLAS Detector

Author: Evan Saraivanov¹

Co-author: Shih-Chieh Hsu²

¹ *University of Washington (US)*

² *University of Washington Seattle (US)*

Corresponding Author: evan.robert.saraivanov@cern.ch

The data set provided by the Large Hadron Collider, with an integrated luminosity of 139.0 fb^{-1} at a center-of-mass energy of $\sqrt{s} = 13 \text{ TeV}$, opens a window to search for new physics beyond the Standard Model (BSM). Searches for a resonance in the dijet mass spectrum are powerful probes of many BSM theories. For particles decaying into light-flavor quarks, inclusive searches provide good sensitivity. For BSM decays to gluons, boosted decision tree (BDT) based gluon taggers using track and calorimeter information can improve the discovery significance. Imperfect modeling of hadronization makes it difficult to calibrate quark/gluon taggers. To calibrate the taggers, a matrix method is applied to find scale factors between the detector and monte-carlo data. In this talk I will present the preliminary scale factors for dijet events along with the systematic uncertainties.

Beyond Standard Model / 118**Probing Extremely Weakly-Interacting Particles in Gamma Factory****Author:** Sreemanti Chakraborti¹**Co-authors:** Jonathan Lee Feng²; James Koga³; Mauro Valli⁴¹ *Indian Institute of Technology, Guwahati, India*² *University of California Irvine (US)*³ *QST*⁴ *University of California, Irvine***Corresponding Author:** sreemanti.c@gmail.com

The Gamma Factory is a proposal to back-scatter laser photons off a beam of partially-stripped ions at the LHC, producing a beam of ~ 10 MeV to 1 GeV photons with intensities of 10^{16} to 10^{18} s⁻¹. This implies $\sim 10^{23}$ to 10^{25} photons on target per year, many orders of magnitude greater than existing accelerator light sources and also far greater than all current and planned electron and proton fixed target experiments. We determine the Gamma Factory's discovery potential through "dark Compton scattering", $\gamma e \rightarrow eX$, where X is a new, weakly-interacting particle. For dark photons and other new gauge bosons with masses in the 1 to 100 MeV range, the Gamma Factory has the potential to discover extremely weakly-interacting particles with just a few hours of data and will probe couplings as low as $\sim 10^{-9}$ with a year of running. The Gamma Factory therefore may probe couplings lower than all other terrestrial experiments and is highly complementary to astrophysical probes. We outline the requirements of an experiment to realize this potential and determine the sensitivity reach for various experimental configurations.

Beyond Standard Model / 119**Search for a Generic Heavy Higgs Boson at ATLAS****Author:** Carter Cheney Vu¹**Co-authors:** Ke Li¹; Shih-Chieh Hsu²¹ *University of Washington (US)*² *University of Washington Seattle (US)***Corresponding Author:** carter.cheney.vu@cern.ch

Many beyond the Standard Model (BSM) theories suggest the existence of multiple fundamental scalar fields and associated Higgs bosons, with the standard model Higgs boson being the lightest and most easily discovered. The dimension-4 interactions between a theorized generic heavy Higgs boson and Standard Model (SM) particles have already been explored in all major Higgs boson production channels, particularly in gluon-gluon fusion, with no evidence of BSM effects so far. Thus, our study takes a new direction by accounting for effective dimension-6 interactions with SM particles in addition to dimension-4 interactions, and by probing the VH channel for a heavy Higgs boson. If the generic heavy Higgs boson is connected with BSM physics at the scale of a few TeV, these dimension-6 operators will dramatically boost heavy Higgs boson momentum such that it can be distinguished from background. This particular region of the phase space has not been investigated by previous LHC studies, enhancing its potential for discovery of BSM physics and a generic heavy Higgs boson.

In this talk, I will present the motivations for the Generic Heavy Higgs Search and the reason for exploring this particular corner of the phase space, as well as the work-in-progress Monte-Carlo kinematic distributions and upper limits describing various signal hypotheses.

The Integration and Commissioning of the Small-Strip Thin Gap Chambers for ATLAS New Small Wheel Phase-I Upgrade

Authors: ATLAS Muon Collaboration^{None}; Prachi Atmasiddha¹

¹ *University of Michigan, Ann Arbor*

Corresponding Author: prachi.atmasiddha@cern.ch

At the high luminosity Large Hadron Collider (LHC), the instantaneous luminosity will be up to $5 - 7.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$. This necessitates the upgrade of the muon spectrometer of the ATLAS detector. The Small Wheel, the innermost station of muon end-cap system, will be replaced by the 'New Small Wheel (NSW)'. For the high luminosity runs, the new system is required to improve trigger selectivity for the end-cap region in a high background environment, while maintaining excellent tracking capability for the events in pp collisions at $\sqrt{s} = 13$ TeV to 14 TeV with the ATLAS detector. To accomplish this, it should deliver hardware-based online track measurements with a pointing accuracy of 1 mrad at Level-1 in the end-cap region. All of this is achieved by two detector technologies, the Small-Strip Thin Gas Chamber (sTGC) and the Micro Mesh Gaseous structures (MM). The sTGC is the primary trigger detector because of its bunch-crossing identification capability. Along with this state of the art detector technology, radiation tolerant custom-made Application-Specific Integrated Circuits (ASICs) are built to create high-speed data inter-connections, which achieve up to 1 MHz of Level-1 data readout using the Back-End FELIX (Front End Link eXchange) system. This complex system of $\sim 400\text{K}$ physical channels and more than $\sim 14\text{K}$ ASICs creates many challenges, which include achieving precise alignment of the readout channels for high spatial resolution and maintain simultaneous trigger and readout with a background rate of $\sim 20 \text{ kHz cm}^{-2}$. The sTGC detector quadruplets are assembled and aligned into wedges at CERN. We summarize our experiences during the sTGC integration and commissioning of the sTGC detector wedges. These studies are performed for the first time together with the final Front-End and Back-End electronics. Our work includes alignment survey of the detector channels, establishing proper connectivity between the detector and the Front-End channels, verifying the robustness of the detector performance against various noise sources, while tuning numerous clock phases and delays for synchronous trigger and readout at high data rate.

Some reflexions on hidden features of SM extensions with scalar triplets

Authors: Bernardo Gonçalves¹; Filipe Joaquim^{None}; Pedro Ferreira^{None}

¹ *CFTP/IST*

Corresponding Author: bernardo.lopes.goncalves@tecnico.ulisboa.pt

The Standard Model of particle physics is in remarkable agreement with most experimental data so far. However, a lot of questions remain unanswered, such as the origin of neutrino masses or the need for extra sources of CP violation. Possible solutions rest on scalar sector extensions, popular beyond-the-Standard-Model scenarios, in which the addition of scalar triplets is an attractive possibility. Such models are much studied in the literature, but they still hide some features underneath. In the Higgs-triplet model, in which small neutrino masses may be generated via the type-II seesaw mechanism, the theory can a priori develop a charge-breaking vacuum as the global minimum of the theory, which would spoil electromagnetism. Furthermore, and although not possible with just one triplet, a CP-breaking vacuum is possible with the addition of two triplets, which could lead to interesting leptonic CP-violating effects. However, it also introduces novel and unexpected features in its scalar spectrum. In this work, we briefly present such hidden features.

Probing the minimal $U(1)$ model at future lepton colliders via the fermion pair-production channel

Authors: Arindam Das¹; Bhupal Dev^{None}; Sanjoy Mandal^{None}; Yutaka Hosotani^{None}

¹ *Hokkaido University*

Corresponding Author: dasarindamphysics@gmail.com

The general $U(1)$ extension of the Standard Model (SM) is a well motivated scenario which has a plenty of new physics options. Such a model is anomaly free which requires to add three generations of the SM singlet right-handed neutrinos (RHNs) which naturally generates the light neutrino masses by the seesaw mechanism. This offers interesting phenomenological aspects in the model. In addition to that the model is equipped with a beyond the SM (BSM) neutral gauge boson, Z' which interacts with the SM and BSM particles showing a variety of new physics driven signatures. After the anomaly cancellation the $U(1)$ charge of the particles are expressed in terms of the SM Higgs doublet and the SM Higgs singlet which allows us to study the interaction of the fermions with the Z' . In this paper we investigate the pair production mechanism of the different charged through the photon, and Z' boson exchange processes at the electron-positron (e^+e^-). The angular distributions, forward-backward (\mathcal{A}), left-right (\mathcal{A}) and left-right forward-backward ($\mathcal{A}_{LR,FB}$) asymmetries of the different charged fermion pair productions show substantial deviation from the SM results

Dark matter and neutrino mass in the radiative seesaw model

Authors: Mrinal Kumar Das¹; Najimuddin Khan²; Pritam Das¹

¹ *Tezpur University*

² *Indian Institute of Technology Indore*

Corresponding Author: khanphysics.123@gmail.com

We study the simplest viable dark matter model with an additional neutral real singlet scalar, including a vectorlike singlet and doublet fermions. We find a considerable enhancement in the allowed region of the scalar dark matter parameter spaces in the presence of these fermions. This model could also accommodate tiny neutrino masses and mixing at one loop-level through the radiative seesaw mechanism. Dilepton + transverse missing energy signature arising from the new fermionic sector can observe at Large Hadron Collider (LHC), satisfying relic density, including other theoretical and experimental bounds. We perform such analysis for a benchmark point in the context of 14 TeV LHC experiments with a future integrated luminosity of 3000 fb^{-1} .

A genuine fermionic quintuplet seesaw model: phenomenological introduction

Authors: Kirtiman Ghosh^{None}; Saiyad Ashanujjaman¹

¹ *Institute of Physics, Bhubaneswar*

Corresponding Author: saiya.a@iopb.res.in

We study a model which generates Majorana neutrino masses at tree-level via low-energy effective operator with mass-dimension-9. The introduction of such a higher dimensional operator brings down the lepton number violating mass scale to TeV making such model potentially testable at present or near future colliders. This model possesses several new $SU(2)_L$ fermionic multiplets, in particular, three generations of triplets, quadruplets and quintuplets, and thus a rich phenomenology at the LHC. Noting that lepton flavour violation arises very naturally in such a setup, we put constraints on the Yukawa couplings and heavy fermion masses using the current experimental bounds on lepton flavour violating processes. We also obtain 95% CL lower bounds on the masses of the triplets, quadruplets and quintuplets using a recent CMS search for multilepton final states with 137 inverse femtobarn integrated luminosity data at 13 TeV centre of mass-energy. The possibility that the heavy fermions could be long-lived leaving disappearing charge track signatures or displaced vertex at the future colliders like LHeC, FCC-he, MATHUSLA, etc. is also discussed.

Neutrinos / 126

Testing the neutrino mass generation mechanism at the colliders

Author: Arindam Das¹

¹ *Hokkaido University*

Corresponding Author: dasarindamphysics@gmail.com

The generation of the neutrino mass is an essential observation from the neutrino oscillation experiments. This indicates a major revision of the Standard Model which initiated with the massless neutrinos. A possible interesting scenario is the seesaw mechanism where SM gauge singlet Right Handed Neutrinos are introduced. Another interesting aspect is the extension of the SM with $SU(2)$ triplet fermions. Alternatively a general $U(1)_L$ extension of the SM is also an interesting idea which involves three generations of the SM singlet RHNs to generate the tiny neutrino mass through the seesaw mechanism. Additionally such models can contain a \prime boson which could be tested at the colliders through the pair production of the RHNs.

Search for Rare Higgs Decays into Z Bosons and J/Psi Mesons or into Quarkonium Pairs with the CMS Experiment

Author: Himal Acharya¹

¹ *University of Tennessee (US)*

Corresponding Author: hacharya@vols.utk.edu

Rare decays of the Higgs boson are promising laboratories to search for physics beyond the standard model (BSM). Such BSM physics might alter Yukawa couplings to lighter quarks and add loop diagrams, possibly resulting in higher decay rates than predicted by the standard model. For the first time in four-lepton final states, decays of the Higgs boson into a ZJ/ψ or $Z\psi(2S)$ final states are searched for. In addition, Higgs decays into J/ψ pair, Υ pair, $\psi(2S)J/\psi$, or $\psi(2S)\psi(2S)$ final states are studied. Events with subsequent decays of the Z boson into lepton pairs (e^+e^- or $\mu^+\mu^-$) and J/ψ or Υ mesons into muon pairs are selected using online event filters. Final states with $\psi(2S)$ mesons are accessed via the inclusive decay of $\psi(2S)$ into J/ψ . A data sample of proton-proton collisions collected at a center-of-mass energy of 13 TeV with the Compact Muon Solenoid detector at the Large Hadron Collider that corresponds to an integrated luminosity of about 137 fb^{-1} is used. This talk will present recent searches and implications for future searches of such BSM signatures with higher luminosities.

W + W – H production through bottom quarks fusion at hadron colliders

Authors: Biswajit Das¹; Pankaj Agrawal²

¹ *Institute Of Physics, Bhubaneswar, India*

² *Institute of Physics, Bhubaneswar, India*

Corresponding Author: biswajit.das@iopb.res.in

With the standard model working well in describing the collider data, the focus is now on determining the standard model parameters as well as for any hint of deviation. In particular, the determination of the couplings of the Higgs boson with itself and with other particles of the model is important to better understand the electroweak symmetry breaking sector of the model. In this letter, we look at the process $pp \rightarrow W W H$, in particular through the fusion of bottom quarks. Due to the non-negligible coupling of the Higgs boson with the bottom quarks, there is a dependence on the $W W H$ coupling in this process. This sub-process receives the largest contribution when the W bosons are longitudinally polarized. We compute one-loop QCD corrections to various final states with polarized W bosons. We find that the corrections to the final state with the longitudinally polarized W bosons are large. It is shown that the measurement of the polarization of the W bosons can be used as a tool to probe the $W W H$ coupling in this process. We also examine the effect of varying $W W H$ coupling in the κ -framework.

Corresponding Author: awaleed@sci.cu.edu.eg

We show that one of the simplest extensions of the Standard Model, the addition of a second Higgs doublet, when combined with a dark sector singlet scalar, allows us to: i) explain the long-standing anomalies in the Liquid Scintillator Neutrino Detector (LSND) and MiniBooNE (MB) while maintaining compatibility with the null result from KARMEN, ii) obtain, in the process, a portal to the dark sector, and iii) comfortably account for the observed value of the muon $g-2$. Three singlet neutrinos allow for an understanding of observed neutrino mass-squared differences via a Type I seesaw, with two of the lighter states participating in the interaction in both LSND and MB. We obtain very good fits to energy and angular distributions in both experiments. We explain features of the solution presented here and discuss the constraints that our model must satisfy. We also mention prospects for future tests of its particle content.

Effective Field Theory interpretation of the VBF HWW differential analysis with the ATLAS detector

Author: Jiayi Chen¹

¹ *Brandeis University (US)*

Corresponding Author: jiayi.chen@cern.ch

An Effective Field Theory (EFT) re-interpretation of the differential measurement of Vector Boson Fusion Higgs production and decay to two W bosons will be reported. The analysis used the full Run-2 data in 2015–2018 of pp collisions at $\sqrt{s}=13$ TeV with the ATLAS detector at the LHC, which correspond to an integrated luminosity of 139 fb^{-1} . Events with an electron and a muon from the decay of the W bosons and two energetic jets in the final state are considered as signals. At particle level, Standard Model predictions can be modified by expressing the differential cross section of various observables as a function of parameters that represent new phenomena predicted by EFT. The background subtracted and unfolded data are used to set limits on these new physics parameters.

Search for four top quark production in the single-lepton final state with the CMS data

Authors: The CMS Collaboration^{None}; Wenyu Zhang¹

¹ *Brown University (US)*

Corresponding Author: wenyu.zhang@cern.ch

We present a search for the standard model four top quark (tttt) production in the single-lepton final state. We analyze the proton-proton collision data collected by the CMS experiment at center-of-mass energy of 13 TeV, corresponding to an integrated luminosity of 35.8 fb^{-1} in 2016, 41.5 fb^{-1} in 2017 and 59.97 fb^{-1} in 2018. The single lepton final state features a high jet multiplicity, with at least four jets coming from the hadronization of a bottom quark, an electron or a muon, and missing transverse momentum from neutrino. We consider the distribution of HT and BDT to discriminate the signal from background, where HT is the scalar sum of transverse momentum of all the jets and BDT is the discriminator from a multivariate analysis based on Boosted Decision Tree approach. We set limits on the four tops production cross section in the absence of signal. The expected limits and significances on tttt production cross section for data-taking period 2016 to 2018, and their combination are presented.

The Mu2e experiment will search for Beyond-the-Standard-Model, Charged Lepton Flavor Violation (CLFV) in the neutrinoless muon-to-electron conversion process $\mu^- + \text{Al} \rightarrow e^- + \text{Al}$. The number of muons stopped and captured by the aluminum Stopping Target is measured by the Stopping Target Monitor (STM) using muon atomic capture x-rays and muon nuclear capture γ -rays. An HPGe detector with $\sim 0.8 \text{ keV}$ Gaussian resolution at 662 keV, and with an estimated photon rate capability of $\sim 100 \text{ kcps}$ along with a LaBr₃ detector with Gaussian energy resolution of 7 keV at 662 keV, with an estimated photon rate capability $\sim 800 \text{ kcps}$ are used to report the muon capture rate. In one beam-on second, 2.3×10^{13} protons hit the Production Target, 3.7×10^{10} muons are stopped in the Stopping Target and together, generate an energy flux of $3.2 \times 10^8 \text{ TeV cm}^{-2} \text{ sec}^{-1}$ consisting of muons, electrons, neutrons, x-rays, and γ -rays, with mean particle energy $\sim 10 \text{ MeV}$. In order to measure the number of stopped muons in the experiment, the energy flux must be reduced by a factor of 5×10^8 for the LaBr₃ detector and 3×10^9 for the HPGe detector. In order to accomplish this reduction, a detector shielding house is placed 35 m from the target, downstream of a beam line consisting of poly absorbers and a sweeping magnet, and containing a tungsten collimator with 0.5 cm^2 apertures. A combination of lead, tungsten, copper and aluminum are layered to achieve the shielding goals. Borated polyethylene is used to absorb neutrons. Separate protection plans are made for the HPGe detector and the LaBr₃ detector because of their different rate and radiation

sensitivities. Rate and energy flux requirement for the detectors are shown to be satisfied using Geant4 simulations.

Measurement of the Z boson production in association with at least two b jets in pp collisions at $\sqrt{s} = 13$ TeV

Authors: Avto Kharchilava¹; Duong Hai Nguyen¹; Hsin-Wei Hsia¹; Peter William Young¹

¹ *The State University of New York SUNY (US)*

Corresponding Author: hsin-wei.hsia@cern.ch

The cross sections of the Z boson production in association with at least two b jets as a function of various kinematic variables are measured in pp collisions at $\sqrt{s} = 13$ TeV using 137 fb^{-1} of data collected by the CMS experiment at LHC. The Z boson decays to electrons or muons are considered with leading (sub-leading) lepton transverse momentum $p_T > 35$ (25) GeV and pseudorapidity $|\eta| < 2.4$, and the invariant mass within 71 and 111 GeV. Jets are selected with $p_T > 30$ GeV and $|\eta| < 2.4$. The results are compared to various QCD calculations.

CaloFlow: Fast and Accurate Generation of Calorimeter Showers with Normalizing Flows

Authors: Claudius Krause¹; David Shih¹

¹ *Rutgers University*

Corresponding Author: claudius.krause@rutgers.edu

We introduce CaloFlow, a fast detector simulation framework based on normalizing flows. For the first time, we demonstrate that normalizing flows can reproduce many-channel calorimeter showers with extremely high fidelity, providing a fresh alternative to computationally expensive GEANT4 simulations, as well as other state-of-the-art fast simulation frameworks based on GANs and VAEs. Besides the usual histograms of physical features and images of calorimeter showers, we introduce a new metric for judging the quality of generative modeling: the performance of a classifier trained to differentiate real from generated images. We show that GAN-generated images can be identified by the classifier with 100% accuracy, while images generated from CaloFlow are able to fool the classifier much of the time. More broadly, normalizing flows offer several advantages compared to other state-of-the-art approaches (GANs and VAEs), including: tractable likelihoods; stable and convergent training; and principled model selection. Normalizing flows also provide a bijective mapping between data and the latent space, which could have other applications beyond simulation, for example, to detector unfolding.

Search for dark matter in events with missing transverse momentum and a Higgs boson decaying to a photon pair in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

Author: Yan Qian¹

Co-author: Sau Lan Wu¹

¹ *University of Wisconsin Madison (US)*

Corresponding Author: yan.qian@cern.ch

We present a search for dark matter production in events with missing transverse momentum and a Higgs boson decaying to a photon pair using 139 fb^{-1} of pp collisions recorded by the ATLAS experiment at a center-of-mass energy of 13 TeV. The search considers three simplified dark matter models which include either vector or pseudo-scalar mediators and predict final states with a pair of dark matter candidates and a Higgs boson. Events are selected using a combination of missing transverse momentum cuts and a boosted decision tree (BDT) trained to separate dark matter signals from background. This talk will focus on the optimization of the BDT training and categorization procedure, resulting in a final selection which provides improved sensitivity to all considered signal models. No significant excess is observed and limits are set on various model parameters such as the mass of the dark matter candidate.

Electrical and functional performance of the first full loaded ITk Strip stave at Brookhaven National Laboratory

Author: Francesca Capocasa¹

¹ *Brandeis University (US)*

Corresponding Author: francesca.capocasa@cern.ch

The ATLAS experiment is currently preparing for an upgrade of the inner tracking detector for High-Luminosity Large Hadron Collider (LHC) operation, scheduled to start in 2027. The new detector, known as the Inner Tracker or ITk, employs an all-silicon design with five inner Pixel layers and four outer Strip layers. The staves are the building blocks of the ITk Strip barrel layers. Each stave consists of a low-mass support structure which hosts the common electrical, optical and cooling services as well as 28 silicon modules, 14 on each side. The first pre-production electrical stave was assembled at Brookhaven National Laboratory in December 2019. To characterize the stave, a set of electrical and functional measurements have been performed both at room and at cold temperature. In this talk I will present the methods used to characterize this stave with particular focus on noise studies.

Reconciling a minimal length scale with lack of photon dispersion

Authors: Douglas Singleton¹; Joey Contreras²; Lee Jaeyeong²; Michael Bishop³

¹ *California State University, Fresno*

² *Fresno State*

³ *CSU Fresno*

Corresponding Author: dougs@mail.fresnostate.edu

Generic arguments lead to the idea of a minimal length scale in quantum gravity. An observational signal of such a minimal length scale is that photons would exhibit dispersion. In 2009, the observation of a short gamma ray burst seemed to push the minimal length scale to distances smaller than the Planck length. This poses a challenge for minimal length models. Here we propose a modification of the position and momentum operators which lead to a minimal length scale, but preserve the photon energy-momentum relationship $E=pc$. In this way there is no dispersion of photons with different energies. This can be accomplished without modifying the commutation relationship $[x,p]=i\hbar$.

² *Lawrence Berkeley National Lab. (US)*

³ *Michigan State University (US)*

Corresponding Author: barnett@lbl.gov

We created an extremely successful planetarium show called: Phantom of the Universe - The Hunt for Dark Matter, which has been seen in more than 600 planetariums in 67 countries and 42 US states. It has been translated into 22 languages. We were motivated in part by envisioning several scenes that could only work in a planetarium. Our target audiences were the public and students. We found that many planetariums had an interest in a dark matter show. They present our show for many months at a time (more than feature films). Planetariums have the perfect science-interested audience for us. None of the physicist organizers had ever made a planetarium show before (involving a spherical screen). To create the show, we worked with renowned people with extensive experience in filmmaking and with people at seven planetariums (in multiple countries). We hired a Hollywood producer and screenwriter. Our narrator for the English-language version was Academy

Award-winning actor Tilda Swinton. Sound editing and sound effects were done by an Academy-Award-winning team at Skywalker Sound. As we developed the show, we never imagined such success.

Beyond the Standard Model Effective Field Theory: The Singlet Extended Standard Model and Higgs Flits

Authors: Ian Lewis¹; Matthew Sullivan²; Matthew Sullivan³; Shekhar Adhikari¹

¹ *The University of Kansas*

² *University of Kansas*

³ *Brookhaven National Laboratory*

Corresponding Author: ian.lewis@ku.edu

One of the assumptions of simplified models is that there are a few new particles and interactions accessible at the LHC and all other new particles are heavy and decoupled. The effective field theory (EFT) method provides a consistent method to test this assumption. Simplified models can be augmented with higher order operators involving the new particles accessible at the LHC. Any UV completion of the simplified model will be able to match onto these beyond the Standard Model EFTs (BSM-EFT). In this paper we study the simplest simplified model: the Standard Model extended by a real gauge singlet scalar. In addition to the usual renormalizable interactions, we include dimension-5 interactions of the singlet scalar with Standard Model particles. As we will show, even when the cutoff scale is 3 TeV, these new effective interactions can drastically change the interpretation of Higgs precision measurements and scalar searches.

Search for Dark Matter from Baryon Number Violation Process in Proton-Proton Collisions at $\sqrt{s}=13$ TeV.

Author: Samila Muthumuni¹

¹ *Texas Tech University (US)*

Corresponding Author: samila.muthumuni@ttu.edu

The visible content of the Universe is made up of baryons and almost without of anti-baryons, so it requires a baryogenesis mechanism to generate the baryon asymmetry and it is widely believed that successful baryogenesis requires extending the Standard Model. There are strong evidence of invisible contents, Dark Matter (DM) in the universe in astrophysical observations, such as rotational curves of galaxies, gravitational lensing and bullet cluster. This analysis searches for the dark matter production in baryon number violation (BNV) process in proton-proton collision. The data sample, collected by the CMS experiment during the 2016-2018 data taking of the LHC, corresponds to an

integrated luminosity of 137 fb^{-1} at a center-of-mass energy of 13 TeV. The events are required to contain missing transverse momentum and one jet with additional b-tagged jet arising from initial-state gluon splitting. The results are interpreted in the context of simple TeV-scale model of BNV in which a heavy colored scalar mediator is produced in down-type quarks interaction ($b+s$ or $b+d$) and decays into DM and one up-type quark (u or c).

First Order Electroweak Phase Transition from Weakly Coupled sub-GeV Physics

Author: Hooman Davoudiasl¹

¹ *BNL*

Corresponding Author: hooman@bnl.gov

We propose that the dynamics of a scalar ϕ of mass $O(10)$ MeV, weakly coupled to the Higgs, can give rise to a first order electroweak phase transition. Vacuum stability close to the weak scale requires a suppressed (maybe vanishing) top Yukawa coupling before the transition, rising to the Standard Model (SM) value later. All SM flavor could appear similarly, after the electroweak phase transition, through dimension-5 interactions of ϕ suppressed by scales from $O(10^3)$ TeV to near Planck mass. The scalar ϕ is long-lived and can yield missing energy signals in rare kaon decays.

Dark Matter / 145**Baryons and Dark Matter from Dark Phase Transitions****Author:** Robert McGehee¹¹ *University of Michigan***Corresponding Author:** rmcgehee@umich.edu

We present two distinct models which rely on 1st order phase transitions in a dark sector. The first is a minimal model for baryogenesis which employs a new dark SU(2) gauge group with two doublet Higgs bosons, two lepton doublets, and two singlets. The singlets act as a neutrino portal that transfers the generated baryon asymmetry to the Standard Model. The model predicts extra relativistic degrees of freedom, exotic decays of the Higgs and Z bosons, and stochastic gravitational waves detectable by future experiments.

The second model additionally produces (asymmetric) dark matter while the dark sector is expanded to an SU(3) \times SU(2) \times U(1) gauge group. Dark matter is comprised of dark neutrons or dark protons and pions. This model is highly discoverable at both dark matter direct detection and dark photon search experiments and the strong dark matter self interactions may ameliorate small-scale structure problems.

Lepton Flavor and Precision Measurements / 146**Cosmic Ray Event Reconstruction in Mu2e****Author:** Mackenzie Devilbiss¹¹ *University of Michigan***Corresponding Author:** macndevv@umich.edu

The Mu2e experiment at Fermilab seeks to observe the ultra-rare conversion of a muon to an electron in a nuclear field, which produces a monoenergetic electron with an energy close to the muon rest mass. This process violates charged lepton flavor number conservation in the Standard Model, and is a clear signal for New Physics if observed. Mu2e's most dangerous source of background is conversion-like events produced from cosmic rays, which can interact with the apparatus and generate fake signal candidates. Cosmic rays are mitigated by an active cosmic ray veto (CRV) detector that surrounds the apparatus. We will briefly summarize the backgrounds to the conversion signal and then dive into how Mu2e detects, reconstructs, and rejects cosmic ray events, including discussion of some recent work that was done to improve the timing reconstruction of the cosmic rays. In this discussion, we study the impact of the signal propagation time through long, up to 6m, scintillating CRV counter bars and the time-of-flight corrections on the cosmic rejection efficiency. These newly introduced corrections will be used to improve the cosmic ray vetoing and optimize event selection.

Higgs & Electroweak Physics / 147**NLO EW corrections to $W^+Z\gamma$ production in SM and tree-level effects of dimension-eight operators in SMEFT at the LHC****Author:** Huanfeng Cheng¹**Co-author:** Doreen Wackerath¹¹ *SUNY Buffalo***Corresponding Author:** huanfeng@buffalo.edu

Triple gauge boson production is an important class of processes at the LHC. It allows measurements to test the quartic gauge couplings in the Standard Model and constrain the non-standard gauge couplings in the Standard Model effective field theory (SMEFT). We perform the computations of the NLO EW and QCD corrections to $W^+Z\gamma$ production with leptonic decays in SM at the LHC. The considered process is $pp \rightarrow e^+ \nu_e \mu^+ \mu^- \gamma$. We study the impacts of the corrections on the total and differential cross sections. We also study the tree-level effects of individual dimension eight operator in SMEFT. The corresponding unitarity bound is derived from partial wave expansions. By showing the interplay between the NLO corrections in SM and the effects of dimension-eight operators in SMEFT, we conclude that the NLO EW corrections are indispensable to test the gauge couplings in SM and draw the limits on the dimension-eight operators in SMEFT precisely.

We explore the implications of $g_\mu - 2$ new result to five models based on the $SU(3)_C \times SU(3)_L \times U(1)_N$ gauge symmetry and put our conclusions into perspective with LHC bounds. We show that previous conclusions found in the context of such models change if there are more than one heavy particle running in the loop. Moreover, having in mind the projected precision aimed by the $g_\mu - 2$ experiment at FERMILAB, we place lower mass bounds on the particles that contribute to muon anomalous magnetic moment assuming the anomaly is resolved otherwise. Lastly, we discuss how these models could accommodate such anomaly in agreement with existing bounds.

Computation, Machine Learning, and AI / 151**The ATLAS Multi-threaded Trigger Selection Framework**

Author: Werner Wiedenmann¹

¹ *University of Wisconsin Madison (US)*

Corresponding Author: werner.wiedenmann@cern.ch

Athena is the software framework used in the ATLAS experiment throughout the data processing path, from the software trigger system through offline event reconstruction to physics analysis. The shift from high-power single-core CPUs to multi-core systems in the computing market means that the throughput capabilities of the framework have become limited by the available memory per process. For Run 2 of the Large Hadron Collider (LHC), ATLAS has exploited a multi-process forking approach with the copy-on-write mechanism to reduce the memory use. To better match the increasing CPU core count and the, therefore, decreasing available memory per core, a multi-threaded framework, AthenaMT, has been designed and is now being implemented. The ATLAS High Level Trigger (HLT) system has been remodelled to fit the new framework and to rely on common solutions between online and offline software to a greater extent than in Run 2.

We present the implementation of the new HLT system within AthenaMT, which is being commissioned now for ATLAS data-taking during LHC Run 3.

Polynomial Inflation and Dark Matter

Authors: Nicolás Bernal¹; Yong Xu²

¹ *Universidad Antonio Nariño*² *Bethe Center for Theoretical Physics, Universität Bonn***Corresponding Author:** yongxu@th.physik.uni-bonn.de

We present a minimal UV complete framework to embed inflation and dark matter by extending the standard model with a singlet real scalar field (the inflaton) and a singlet fermionic field acting as dark matter. The inflaton features the most general renormalizable polynomial up to quartic order, which is flat due to the existence of a perturbed inflection-point, comfortably fitting CMB measurements. We also analyze (p)reheating by considering the Higgs production via inflaton decay. In the early universe, dark matter can be generated by the mediation of gravitons or inflatons. However, the production via the direct decay of the inflatons dominates, making viable a large range of dark matter masses, from $\mathcal{O}(10^{-5})$ GeV to $\mathcal{O}(10^{11})$ GeV.

Search for a Light Pseudoscalar Higgs Boson in the Two Higgs Doublet Model using Data from the Large Hadron Collider (LHC)

Authors: Fengwangdong Zhang¹; Redwan Md Habibullah²; Grace Haza¹; Jingyu Zhang²; Maxwell Chertok¹; Rachel Yohay²

¹ *University of California Davis (US)*² *Florida State University (US)***Corresponding Author:** redwan.habibullah@cern.ch

A search is presented for a light pseudoscalar Higgs boson (a) using data collected by the CMS experiment at LHC, at the center-of-mass of energy of 13 TeV. The study looks into the decay Higgs boson (H) via the $H \rightarrow aa \rightarrow \mu\mu\tau\tau$ channel. The Higgs boson can be both standard-model-like (125 GeV) or heavier. The pseudoscalar mass falls within the range $m_a \in [2m_\tau, m_H/2]$. The large mass difference between the Higgs and the pseudoscalar means that the final tau lepton decay products are highly boosted in the decay direction and collimated. A modified version of tau reconstruction is used to account for the highly overlapping decay products. The modified reconstruction technique gives higher reconstruction efficiency over the standard tau reconstruction and hence better signal significance and background rejection. This technique also becomes useful when looking into various final states, especially the ones where one of the taus decays hadronically while the other decays leptonically (μ/e). The performance of the altered reconstruction technique, as opposed to the standard tau reconstruction, is also presented. The results from the 2016 and 2017 CMS datasets will be shown.

Massless Preheating and Electroweak Vacuum Metastability

Author: Jeff Kost¹

Co-authors: Chang Sub Shin ²; Takahiro Terada ²

¹ *University of Sussex*

² *IBS-CTPU*

Corresponding Author: jeffreydkost@gmail.com

Current measurements of Standard-Model parameters suggest that the electroweak vacuum is metastable. This metastability has important cosmological implications because large fluctuations in the Higgs field could trigger vacuum decay in the early universe. For the false vacuum to survive, interactions which stabilize the Higgs during inflation—e.g., inflaton-Higgs interactions or non-minimal couplings to gravity—are typically necessary. However, the post-inflationary preheating dynamics of these same interactions could also trigger vacuum decay, thereby recreating the problem we sought to avoid. This dynamics is often assumed catastrophic for models exhibiting scale invariance since these generically allow for unimpeded growth of fluctuations. In this talk, we examine the dynamics of such “massless preheating” scenarios and show that the competing threats to metastability can nonetheless be balanced to ensure viability. We find that fully accounting for both the backreaction from particle production and the effects of perturbative decays reveals a large number of disjoint “islands of (meta)stability” over the parameter space of couplings. Ultimately, the interplay among Higgs-stabilizing interactions plays a significant role, leading to a sequence of dynamical phases that effectively extend the metastable regions to large Higgs-curvature couplings.

CMB Birefringence due to ultralight axion string networks

Author: Mudit Jain¹

Co-authors: Mustafa Amin¹; Andrew Long¹

¹ *Rice University*

Corresponding Authors: mustafa.a.amin@rice.edu, andrewjlong@rice.edu

Ultralight axions (ULA), whose masses can lie in a wide range of values and can be even smaller than 10^{-28} eV, are generically predicted in UV theories such as string theory. In the cosmological context, the early Universe may have gotten filled with a network of ultralight axion (ULA) cosmic strings which, depending upon the mass of the axion, can survive till very late times. If the ULA also couples to electromagnetism, and the network survives post recombination, then the interaction between the strings and the CMB photons induces a rotation of the polarization axis of the CMB photons (otherwise known as the birefringence effect). This effect is independent of the string tension, and only depends on the coupling between the ULA and the photon (which in turn is sensitive to UV physics). In this talk I will present some results for this birefringence effect on CMB, due to three different models of string network. Interestingly, this is within the reach of some current and future CMB experiments.

The CMS Electromagnetic Calorimeter calibration and performance during LHC Run 2

Author: Jelena Mijuskovic¹

¹ *University of Montenegro (ME)*

Corresponding Author: jelena.mijuskovic@cern.ch

The CMS electromagnetic calorimeter (ECAL) of the Compact Muon Solenoid (CMS) is a high granularity lead tungstate crystal calorimeter operating at the CERN Large Hadron Collider. The ECAL is designed to achieve excellent energy resolution which is crucial for studies of Higgs boson decays with electromagnetic particles in the final state, as well as for searches for new physics involving electrons and photons. Recently the energy response of the calorimeter has been precisely calibrated exploiting the full Run 2 data, with the goal of achieving the most optimal performance. A dedicated calibration of each detector channel has been performed with physics events using electrons from W and Z boson decays, photons from π^0/η decays, and the azimuthally symmetric energy distribution of minimum bias events. We will describe the calibration strategies that have been implemented and the excellent performance achieved by the CMS ECAL with the ultimate calibration of Run 2 data, in terms of energy scale stability and energy resolution.

IceCube-Upgrade Reconstructions using Recurrent Neural Networks

Author: Brandon Pries¹

¹ *Michigan State University*

Corresponding Author: priesbr1@msu.edu

Neutrinos offer a variety of insights into Standard Model physics that are not yet understood, including flavor oscillations and the neutrino mass ordering. One instrument being used to study neutrinos is the IceCube South Pole Neutrino Observatory, a cubic kilometer-scale Cherenkov detector over 1.5 km below the South Pole. An extension, the IceCube-Upgrade, is currently under development and is designed to enhance the detector's low-energy performance. The DOMs detect Cherenkov radiation from neutrino interactions within the ice. Using features of the recorded light, such as arrival time and intensity, we can reconstruct neutrino properties such as energy and direction. Reconstructing neutrino events in IceCube is difficult at lower energies (below 100 GeV) due to both the lower number of Cherenkov photons produced during interactions, as well as the large spacing between DOMs, which is optimized for higher-energy events. One way to reconstruct these events is with neural networks, specifically Recurrent Neural Networks (RNNs). RNNs excel at handling data with a sequential relationship such as time, which makes them a great candidate for reconstructing particle interactions. This study highlights the results of an RNN trained to reconstruct the energy and direction of low-energy neutrinos using IceCube-Upgrade simulation; we also provide a comparison to an existing likelihood-based reconstruction.

Resonant Self Interacting Dark Mesons from Hidden QCD

Author: Yu-Dai Tsai¹

¹ *Fermilab***Corresponding Author:** ytsai@fnal.gov

We present models of resonant self-interacting dark matter in a dark sector with QCD, based on analogies to the meson spectra in Standard Model QCD. For dark mesons made of two light quarks, we present a simple model that realizes resonant self-interaction (analogous to the ϕ -K-K system) and thermal freeze-out. We also consider asymmetric dark matter composed of heavy and light dark quarks to realize a resonant self-interaction (analogous to the Y(4S)-B-B system) and discuss the experimental probes of both setups. Finally, we comment on the possible resonant self-interactions already built into SIMP and ELDER mechanisms while making use of lattice results to determine feasibility.

Field and String Theory / 162**Wormholes and black hole microstates in AdS/CFT****Author:** Kristan Jensen¹**Co-author:** Jordan Cotler²¹ *University of Victoria*² *Harvard University***Corresponding Author:** kristanj@uvic.ca

It has long been known that the coarse-grained approximation to the black hole density of states can be computed using classical Euclidean gravity. In this talk I will present evidence for another entry in the dictionary between Euclidean gravity and black hole physics, namely that Euclidean wormholes describe a coarse-grained approximation to the energy level statistics of black hole microstates. Our main result is an integral representation for wormhole amplitudes in Einstein gravity and in full-fledged AdS/CFT. These amplitudes are non-perturbative corrections to the two-boundary problem in AdS quantum gravity. The full amplitude is UV sensitive, dominated by small wormholes, but it admits an integral transformation with a macroscopic, weakly curved saddle-point approximation. In the boundary description this saddle appears to dominate a smeared version of the connected two-point function of the black hole density of states, and suggests level repulsion in the spectrum of AdS black hole microstates.

Higgs & Electroweak Physics / 163**Optimization of sensitivity for the Di-Higgs search in b $Barbl\nu qq$ final state in the LHC data recorded by the ATLAS detector in pp collisions at $\sqrt{s} = 13$ TeV****Author:** Pratik Kafle¹¹ *Ohio State University (US)*

Corresponding Author: pratik.kafle@cern.ch

A study of optimization of signal sensitivity in the search for the Di-Higgs event in the ATLAS experiment is presented where one of the Higgs bosons decays via the $H \rightarrow b\bar{b}$ channel and the other via $H \rightarrow WW^*$ with b decay as the final state. Large irreducible background contamination from $t\bar{t}$ decay significantly decreases the signal sensitivity in the Di-Higgs search. We employ ROOT's built-in Multivariate analysis tool (TMVA) to train new physics-motivated variables along with currently trained variables. An increment in the rejection of $t\bar{t}$ background while keeping the signal efficiency high is observed.

New Low Scale Baryogenesis

Author: Tony Menzo¹

Co-authors: Jure Zupan²; Julia Gehrlein

¹ *University of Cincinnati*

² *University of Cincinnati*

Corresponding Author: menzoad@mail.uc.edu

We present a novel mechanism for baryogenesis via a low scale leptogenesis. The mechanism consists of two parts: first, out of equilibrium sub-weak-scale CP asymmetric decays of heavy sterile neutrinos result in leptogenesis carried by lighter sterile neutrinos. Second, the lepton asymmetry is transferred into a baryon asymmetry via baryon number violating scatterings of the light neutrino, dark states and neutrons. We show that the mechanism produces lepton and baryon abundances in agreement with current observational constraints. Finally, we discuss relevant phenomenology and potential signatures.

The Inner Tracker is an all-silicon detector that will replace ATLAS' inner tracking layers for the High Luminosity LHC. SLAC National Accelerator Laboratory is responsible for the loading and integration of the pixel layers closest to the LHC Beamline, the Inner System. We'll mount the silicon pixel detectors on their mechanical supports, then connect the loaded mechanical supports ("loaded local supports") to integrate the full Inner System. This talk will present the loading of the first thermomechanical local support prototype.

Pion Production Optimization for Mu2e

Author: Helenka Casler¹

¹ *City University of New York / York College campus*

Corresponding Author: hcasler@gradcenter.cuny.edu

The Mu2e experiment, currently under construction at Fermilab, will search for charged lepton flavor violation (CLFV) in the form of coherent neutrinoless conversion of muons to electrons in the presence of an atomic nucleus. In order to reach its projected single-event sensitivity of 3×10^{-17} , Mu2e will need to create the most intense muon beam ever developed, with 10^{10} muons per second stopping in the stopping target. These muons will be produced from pions originating from the production target. Optimizing pion production is therefore a vital component of the Mu2e design. This talk will discuss how the design of the production target, solenoid, and instrumentation is optimized for pion production.

A systematic approach to neutrino masses and their phenomenology

Author: Michael Schmidt¹

¹ *UNSW Sydney*

Corresponding Author: m.schmidt@unsw.edu.au

We propose a model-independent framework to classify and study neutrino mass models and their phenomenology. The idea is to introduce one particle beyond the Standard Model which couples to leptons and carries lepton number together with an operator which violates lepton number by two units and contains this particle. This allows to study processes which do not violate lepton number, while still working with an effective field theory. The contribution to neutrino masses translates to a robust upper bound on the mass of the new particle. We compare it to the stronger but less robust upper bound from Higgs naturalness and discuss several lower bounds.

Search for Dark Matter produced in association with a Higgs boson decaying to a pair of b quarks at 13 TeV with the ATLAS detector

Author: Tuan Minh Pham¹

Co-author: Sau Lan Wu¹

¹ *University of Wisconsin Madison (US)*

Corresponding Author: tuan.minh.pham@cern.ch

We present a search for dark matter candidates produced in association with a Higgs boson using data collected from pp collision at $\sqrt{s} = 13$ TeV with the ATLAS detector that corresponds to an integrated luminosity of 139 fb^{-1} . This search targets events that contain a large missing transverse momentum and a Higgs boson reconstructed either as two b -tagged small-radius jets or as a single large-radius jet associated with two b -tagged sub-jets. Compared to the previous iteration, this search represents an optimised event selection and advances in object identification that enhance the expected sensitivity and simplify the analysis. No significant excess from the Standard Model prediction is observed. The results are interpreted in two benchmark models with a Two-Higgs-Doublet extended by either a heavy vector boson Z' or a pseudoscalar singlet a which provide dark matter candidates.

Corresponding Author: rhitaja@iisc.ac.in

Sophisticated machine learning techniques have promising potential in search for physics beyond Standard Model in Large Hadron Collider (LHC). Convolutional neural networks (CNN) can provide powerful tools for differentiating between patterns of calorimeter energy deposits by prompt particles of Standard Model and displaced particles coming from decay of long-lived particles predicted in various models beyond the Standard Model. We demonstrate the usefulness of CNN by using a couple of physics examples from well motivated BSM scenarios predicting long-lived particles giving rise to displaced jets. Our work suggests that modern machine-learning techniques have potential to discriminate between energy deposition patterns of prompt and displaced particles, and thus, they can be useful tools in such searches.

Colliding light: photon fusion production at ATLAS

Author: Jesse Liu¹

¹ *University of Chicago*

Corresponding Author: jesse.liu@cern.ch

What happens when we collide light at the highest laboratory energies? LHC beams source energetic photons that can collide to create new particles. Recently, ATLAS reported the landmark observation of photon-induced W boson pairs in the electron–muon channel using 139 fb^{-1} of $\sqrt{s} = 13 \text{ TeV}$ proton–proton collision data. A hallmark of photon fusion production is the forward scattering of protons, which was recently measured using the ATLAS Forward Proton spectrometer in association with electron and muon pairs using 14.6 fb^{-1} of data. Moreover, 2.2 nb^{-1} of $\sqrt{s_{NN}} = 5.02 \text{ TeV}$ lead–lead collision data enabled the observation of light-by-light scattering and search for axion-like particles in diphoton final states. This talk summarizes these remarkable experimental advances using the LHC as a photon collider, opening novel probes of the Standard Model and beyond in uncharted regimes.

Beyond Standard Model / 172**Search for charged Higgs bosons decaying via $H^\pm \rightarrow \tau^\pm \nu_\tau$ in the τ +jets and τ +lepton final states in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS experiment****Author:** Elliot Parrish¹¹ Northern Illinois University**Corresponding Author:** elliot.wesley.parrish@cern.ch

Charged Higgs bosons produced either in top-quark decays or in association with a top-quark, subsequently decaying via $H^\pm \rightarrow \tau^\pm \nu_\tau$, are searched for in 36.1 fb^{-1} of proton-proton collision data at $\sqrt{s} = 13$ TeV recorded with the ATLAS detector. Depending on whether the associated top-quark decays hadronically or leptonically, the search targets τ +jets and τ +lepton final states. In both cases, the τ -lepton decays hadronically. No evidence of a charged Higgs boson is found. For the mass range of $m_{H^\pm} = 90\text{-}2000$ GeV, upper limits at the 95% confidence level are set on the production cross-section of the charged Higgs boson times the branching fraction $\text{calB}(H^\pm \rightarrow \tau^\pm \nu_\tau)$ in the range $4.2\text{-}0.0025$ pb. In the mass range $90\text{-}160$ GeV, assuming the Standard Model cross-section for $t\bar{t}$ production, this corresponds to upper limits between 0.25% and 0.031% for the branching fraction $\text{calB}(t \rightarrow bH^\pm) \times \text{calB}(H^\pm \rightarrow \tau^\pm \nu_\tau)$. In the newest iteration of the search, the mass range has been extended to $m_{H^\pm} = 80\text{-}3000$ GeV and novel machine learning techniques have been developed to sift through 139 fb^{-1} of data. A parameterized neural network (PNN) is trained across the entire mass spectrum to provide signal-background discrimination in τ +jets or τ +lepton final states.

Higgs & Electroweak Physics / 173**Search for the Decay of the Higgs Boson to Charm Quarks with the ATLAS Experiment****Author:** Zijun Xu¹¹ SLAC National Accelerator Laboratory (US)**Corresponding Author:** zijun.xu@cern.ch

The measurements at the Large Hadron Collider(LHC), so far, have established Higgs Yukawa couplings to Fermions are close to the Standard Model(SM) expectation for the 3rd Fermion generation. However, the rather ad hoc assumption of universal Yukawa coupling for other Fermion generations has a little experimental constraint. This is very challenging to probe due to small branching fractions, extensive quantum chromodynamics(QCD) backgrounds, and difficulties in jet flavor identification. A direct search by the ATLAS experiment for the SM Higgs boson decaying to a pair of charm quarks is presented. The dataset delivered by the LHC in pp collisions at $\sqrt{s} = 13$ TeV and recorded by the ATLAS detector corresponds to an integrated luminosity of 139 fb^{-1} . Charm tagging algorithms are optimized to distinguish c-quark jets from both light flavor jets and b-quark jets. The analysis method is validated with the study of diboson (WW, WZ, and ZZ) production, with observed (expected) significances of 2.6(2.2) standard deviations above the background-only hypothesis for the $(W/Z)Z(\rightarrow c\bar{c})$ process and 3.8(4.6) standard deviations for the $(W/Z)W(\rightarrow c\bar{q})$ process. The $(W/Z)H(\rightarrow c\bar{c})$ search yields an observed (expected) limit of 26(31) times the predicted cross-section times branching fraction for a Higgs boson with a mass of 125 GeV, corresponding to an observed (expected) constraint on the charm Yukawa coupling modifier $|\kappa_c| < 8.5(12.4)$, at the 95% confidence level.

Convolutional Neural Network Reconstruction of Neutrino Event Interaction Vertex in IceCube

Author: Julia Willison^{None}

Corresponding Author: julia.frances.marnie@gmail.com

The IceCube Neutrino Observatory detects atmospheric and astrophysical neutrinos using a cubic kilometer of ice instrumented with optical sensors at the South Pole. Neutrinos are detected using these sensors which record the cone of light from Cherenkov radiation, emitted by charged particles moving faster than the speed of light in ice, allowing the event vertex of neutrino interactions to be reconstructed. Low energy events are difficult to detect in IceCube because the detector is sparse and there is less Cherenkov radiation emitted, so optimized reconstruction methods are required. Reconstructing the event vertex in particular is important to ensure that the events are contained in the detector, and to allow us to remove background atmospheric muons and other noise. Current and past reconstruction methods have been likelihood-based, however, these methods are computationally intensive. We utilized a Convolutional Neural Network, which has proven to be faster than the likelihood-based methods, and has comparable resolution for vertex reconstruction.

Reinterpretation of the ATLAS Search for Displaced Hadronic Jets with the RECAST Framework

Author: Mason Proffitt¹

¹ *University of Washington (US)*

Corresponding Author: mason.louis.proffitt@cern.ch

A search for neutral long-lived particles decaying into displaced jets in the ATLAS hadronic calorimeter in pp collisions at $\sqrt{s} = 13$ TeV during 2016 with data corresponding to 10.8 fb^{-1} or 33.0 fb^{-1} of integrated luminosity (depending on the trigger) is preserved in RECAST and thereafter used to constrain three new physics models not studied in the original work. A Stealth SUSY model and a Higgs-portal baryogenesis model, both predicting long-lived particles and therefore displaced decays, are probed for proper decay lengths between a few cm and 500 m. A dark sector model predicting Higgs and heavy boson decays to collimated hadrons via long-lived dark photons is also probed. The cross-section times branching ratio for the Higgs channel is constrained between a few millimeters and a few meters, while for a heavier 800 GeV boson the constraints extend from tenths of a millimeter to a few tens of meters. The original data analysis workflow was completely captured using virtualization techniques, allowing for an accurate and efficient reinterpretation of the published result in terms of new signal models following the RECAST protocol.

Higgs & Electroweak Physics / 176**A measurement of the $D^* \rightarrow \pi(K\pi\pi^0)$ decay channel as pertaining to the production of a W boson in association with a charm quark in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS Detector****Author:** Rohith Anand Karur¹**Co-author:** Heather Gray²¹ Lawrence Berkeley National Lab. (US)² UC Berkeley/LBNL**Corresponding Author:** r_karur137@berkeley.edu

The measurement of the production of a W boson with a c quark (termed “ $W + c$ analysis”) is studied with the ATLAS detector using the full Run 2 dataset of pp collisions at $\sqrt{s} = 13$ TeV. This measurement is crucial in obtaining increasingly precise values of the s and \bar{s} parton distribution function (PDF) of the proton, as well as studying the physics of the charm quark. One of the decay modes through which $W + c$ analysis can be performed is the so-called “Satellite” mode, where a D^* decays according to: $D^* \rightarrow \pi D^0 \rightarrow \pi(K\pi\pi^0)$, and a W boson decays leptonically. We present the measurement of the cross section of $W^+ + D^{*-}, W^- + D^{*+}$, and the ratio of these cross sections $R_c^\pm(WD^*)$ using the Satellite mode in pp collisions at $\sqrt{s} = 13$ TeV. Specifically, we measure the scaling factor μ (which scales Standard Model predictions to observed data) for each charged lepton channel to be: $\mu(e^-) : 1.15 \pm 0.07$, $\mu(e^+) : 1.08 \pm 0.07$, $\mu(\mu^-) : 1.11 \pm 0.07$, and $\mu(\mu^+) : 1.06 \pm 0.09$. Additionally, we calculate a first pass value of $R_c^\pm(WD^*)$ to be 0.92, and we bound the uncertainty on this ratio to be $\sigma(R_c^\pm(WD^*)) < 0.06$.

Beyond Standard Model / 177**Searching for a new leptophilic vector boson Z' with four-muon final state with the ATLAS detector****Author:** Shuzhou Zhang¹¹ University of Michigan (US)**Corresponding Author:** shuzhou.zhang@cern.ch

The talk presents a search for a new leptophilic vector boson Z' decaying into the four-muon final state using the data collected by ATLAS detector in the year 2015-2018. A moderate excess of 4μ events with a $\mu^+\mu^-$ pair is the experimental signature for this study. The gauge boson Z' is predicted by the highly motivated gauged $U(1)_{L\mu}$ model, which is the simplest extension of the Standard Model (SM). The model addresses the observed $g-2$ of the muon anomalous magnetic dipole moment and the B physics anomalies. At the same time, the model probes physics and cosmology outstanding questions related to the dark matter and neutrino mass.

Designing adversarial machine learning techniques to tag displaced jets in the ATLAS calorimeter

Author: Felix Cormier¹¹ *University of British Columbia (CA)***Corresponding Author:** felix.cormier@cern.ch

The ATLAS detector was designed to detect prompt particles from the LHC. A pair of long-lived particles, as part of a new Hidden Sector added to the Standard Model, would lead to challenging reconstruction and differentiating from background in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector. The two main backgrounds to a search for such long-lived particles are QCD multijet and Beam-induced Background (BIB), the latter being muons arising from proton bunch interaction with LHC collimators or beam gas which then deposit energy in the calorimeter. Beam-induced background is non-standard and mimics signal very well, such that an algorithm is used to isolate a sample of BIB jets in ATLAS data which is used to train a neural network. This neural network was designed to take low-level variables from the ATLAS tracker, calorimeters and muon system through 1D convolutions and an LSTM to take advantage of the natural ordering and correlations of those subsystems' constituents, and uses this to discriminate between signal, QCD and BIB jets.

Due to the BIB background requiring the use of data in training an adversarial network was added to reduce the effect of simulation/data differences into the final NN score. The adversary is instrumental in controlling systematic uncertainties, using a novel technique which trains on both signal and background to reduce the effects of simulation/data mis-modelling. To do this, a control region is constructed containing a multijet selection and signal trigger veto of both data and simulation. This way, the same population of jets in both data and simulation could be studied, such that the only difference would be mis-modelling in the input variables. The adversary uses this control region to ignore the mis-modelling while discriminating between signal, QCD and BIB.

Search for Higgs boson decays to bottom quarks in the vector boson fusion production mode with the ATLAS detector

Author: Matthew Henry Klein¹¹ *University of Michigan (US)***Corresponding Author:** matthew.henry.klein@cern.ch

The Higgs Boson is expected to decay to bb approximately 58% of the time. Despite the large branching fraction, due to the large background from Standard Model events with b -jets, measuring this decay has been less precise than other, less frequent, decays. Measuring $H(bb)$ in the vector boson fusion production mode has historically been insensitive, but developments in the background estimates and discrimination, as well as improvements in the signal extraction techniques, have resulted

in an observed (expected) significance of 2.6 (2.8) standard deviations from the background-only hypothesis. This analysis uses a dataset with an integrated luminosity of 126 fb^{-1} , collected in pp collisions at $\sqrt{s} = 13 \text{ TeV}$ with the ATLAS detector at the Large Hadron Collider (LHC) during LHC Run 2 and considers only fully-hadronic final states. This talk will focus on the background estimation and signal extraction techniques that are unique to this analysis, as well as the results.

“Study of QCD phenomena in Z+Heavy-Flavor jet measurements performed on Run-2 ATLAS data at $\sqrt{s} = 13 \text{ TeV}$ ”

Author: Alec Swenson Drobac¹

Co-author: Pierre-Hugues Beauchemin¹

¹ *Tufts University (US)*

Corresponding Author: alec.drobac@gmail.com

Measurements of the production rate of Z bosons in association with heavy quarks provide sensitive tests of perturbative quantum chromodynamics (pQCD) predictions, which are made at next-to-leading-order (NLO) accuracy using either a 4-flavor number scheme (4FNS) or 5-flavor number scheme (5FNS). In the 4FNS, b-quarks are not present in the parton distribution functions (PDFs) and only appear as a product of gluon splitting ($g \rightarrow b\bar{b}$). In the 5FNS, on the other hand, a (massless) b-quark PDF is included. A previous analysis studying Z + b-jet events using 2015 & 2016 data showed that the 5FNS predictions match the data well, while the 4FNS predictions underestimate the data. The uncertainties are substantial, however. In our analysis we are attempting to further investigate these results by also including Z + c-jet events and looking at the combined “heavy-flavor” (b+c) region to reduce uncertainties. We are also updating the 2015-2016 results with 140 fb^{-1} of ATLAS Run-2 data at $\sqrt{s} = 13 \text{ TeV}$. This is still a work in progress, but important milestones will be presented.

The Photon PDF within the CT18 global analysis

Authors: C.-P. Yuan¹; Keping Xie²; Carl Schmidt¹; Mengshi Yan³; TIMOTHY J HOBBS⁴; Tie-Jiun Hou⁴

¹ *Michigan State University*

² *University of Pittsburgh*

³ *Peking University*

⁴ *Southern Methodist University*

Corresponding Author: kex10@pitt.edu

Building upon the most recent CT18 global fit, we present a new calculation of the photon content of proton based on an application of the LUXqed formalism. In this work, we explore two principal variations of the LUXqed ansatz. In one approach in which we designate CT18lux, the photon PDF is calculated directly using the LUXqed formula for all scales, Q . In an alternative realization, CT18qed, we instead initialize the photon PDF in terms of the LUXqed formulation at a lower scale, $Q \sim Q_0$, and evolve to higher scales with a combined QED+QCD kernel at $\mathcal{O}(\alpha)$, $\mathcal{O}(\alpha\alpha_s)$ and $\mathcal{O}(\alpha^2)$. While we find these two approaches generally agree, especially at intermediate x ($10^{-3} < x < 0.3$), we discuss some moderate discrepancies that can occur toward the end-point regions at very high or low x .

We also study effects that follow from variations of the inputs to the LUXqed calculation originating outside the purely DIS region, including from elastic form factors and other contributions to the photon PDF. Finally, we investigate the phenomenological implications of these photon PDFs at the LHC, including high-mass Drell-Yan, vector-boson pair, top-quark pair, and Higgs+vector-boson production.

Search for Heavy (pseudo)Higgs boson A/H produced in association with a top-antitop quark pair leading to the final state with four top quarks in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

Author: Meng-Ju Tsai¹

¹ *University of Michigan*

Corresponding Author: metsai@umich.edu

Four top-quark production, a rare process in the Standard Model (SM) with a cross-section around 12 fb, is one of the heaviest final states produced at the LHC, and it is naturally sensitive to physics beyond the Standard Model (BSM). A data excess is observed with twice of the expectation. A follow-up analysis is the search for Heavy (pseudo)Higgs boson A/H produced in association with a top-antitop quark pair leading to the final state with four top quarks. The data analyzed correspond to an integrated luminosity of 139 fb^{-1} of proton-proton collision data at a centre-of-mass energy of 13 TeV collected by the ATLAS detector at the LHC. In this talk, the four top-quark decay final states containing either a pair of same-sign leptons or multi-lepton (SSML) are considered. To enhance the search sensitivity, a mass-parameterized BDT is introduced to discriminate the BSM signal against the irreducible SM four-top and other dominant SM backgrounds. Expected upper bounds on the production cross-section of A/H are derived in the mass range from 400 GeV to 1000 GeV.

Probing the standard cosmological model with the population of binary black-holes

Author: Jose Maria Ezquiaga¹

¹ *University of Chicago*

Corresponding Author: ezquiaga@uchicago.edu

Gravitational-wave (GW) detections are rapidly increasing in number, enabling precise statistical analyses of the population of compact binaries. In this talk I will show how these population analyses cannot only serve to constrain the astrophysical formation channels, but also to learn about cosmology. The three key observables are the number of events as a function of luminosity distance, the stochastic GW background of unresolved binaries and the location of any feature in the source mass distribution, such as the expected pair instability supernova (PISN) gap. Given data from LIGO-Virgo observations, I will present constraints in cosmological modifications of gravity. I will also discuss future prospects on measuring H_0 given a possible population of black holes above the PISN gap. These novel tests of the standard cosmological model require GW data only and will become increasingly relevant as GW catalogs grow, specially if multi-messenger events remain elusive.

The AMAC ASIC for the ATLAS ITk silicon strip detector: Results of prototype wafer testing

Author: Luis Felipe Gutierrez Zagazeta¹

¹ *University of Pennsylvania (US)*

Corresponding Author: luis.felipe.gutierrez.zagazeta@cern.ch

A new silicon strip charged particle detector (ITk strips) is a major component of the future upgrade of the ATLAS experiment for the high luminosity LHC. The Autonomous Monitoring and Control (AMAC) chip is an application specific integrated circuit designed to monitor voltages and currents on each ITk module, and to control power to the front-end readout electronics. To guarantee the reliability of the AMAC, a comprehensive probe station testing procedure has been developed, which allows for the testing of the digital and analog functionality of every AMAC to be installed in an ITk module. To date, the probe station has successfully tested over one thousand prototype AMAC chips, validating most of the functionality while also identifying non-optimal features that will be adjusted in the newer chip version. I will present the probe-station setup, the functionality of the AMAC that was tested, and the results of probing the wafers with prototypes.

ttH and ttW analysis in multileptons channel

Author: Rohin Thampilali Narayan¹

¹ *Southern Methodist University (US)*

Corresponding Author: rohin.narayan@cern.ch

The Large Hadron Collider (LHC) is a “top quark factory”. It allows for precise measurements of several top quark properties. In addition to this, for the first time ever it is now possible to measure rare processes involving top quarks. Associated production of top and anti-top quarks along with the Higgs boson or with electro-weak gauge bosons like W or Z has been observed at the LHC. Precise measurements of these processes have implications on the Standard Model of particle physics and even in cosmology. Recent results from measurements of these rare top quarks processes involving multileptonic final states, at the ATLAS experiment in $\sqrt{s} = 13$ TeV with 80 fb⁻¹ of data will be discussed.

Solving Adjoint QCD₂ with Asymptotic Basis Functions

Author: Uwe Trittman¹

¹ *Otterbein University*

Corresponding Author: utrittman@otterbein.edu

A method to construct the asymptotic eigenstates of two-dimensional adjoint QCD in all parton sectors is described. It is used to explain known properties of the spectrum of QCD_{2A}, as well as the basis of a numerical approach to tackle the full theory. First results in a discrete approximation and a continuous formulation are presented. Prospects to uncover the true single-particle content of the theory are discussed.

The Singly-Charged Scalar Singlet as the Origin of Neutrino Masses

Authors: Juan Herrero¹; Michael Schmidt²; Tobias Felkl³

¹ *IFIC, UV/CSIC*

² *UNSW Sydney*

³ *University of New South Wales*

Corresponding Author: tobiasfelkl@gmx.net

We consider the generation of neutrino masses via a singly-charged scalar singlet. Under general assumptions we identify two distinct structures for the neutrino mass matrix which are realised in several well-known radiative models. Either structure implies a constraint for the antisymmetric Yukawa coupling of the singly-charged scalar singlet to two left-handed lepton doublets, irrespective of how the breaking of lepton-number conservation is achieved. The constraint disfavors large hierarchies among the Yukawa couplings. We study the implications for the phenomenology of lepton-flavour non-universality, measurements of the W -boson mass, flavour violation in the charged-lepton sector and decays of the singly-charged scalar singlet. We also discuss the parameter space that can address the Cabibbo Angle Anomaly.

A last chance for kinetic mixing: Explaining $(g - 2)_\mu$ with semi-visible dark photons

Author: Matheus Hostert¹

Co-authors: Daniele Massaro²; Silvia Pascoli³; Asli Abdullahi⁴

¹ *University of Minnesota*

² *Università di Bologna*

³ *Duke University (US)*

⁴ *University of Durham*

Corresponding Author: mhostert@umn.edu

We revisit the solution to the $(g - 2)_\mu$ puzzle based on a kinetically mixed dark photon. Despite this scenario being excluded in minimal models with fully visible and fully invisible dark photon decays, we show that semi-visible scenarios are still allowed by explicitly re-evaluating constraints from B-factories and fixed-target experiments. Such a solution points to dark photons with masses around a few GeV that couple to dark sectors with co-annihilating dark matter particles or heavy neutral leptons. In all models, we predict a large rate of multi-leptons at Belle-II and NA64.

Dark Matter / 193**Superfluid EFT for sub-GeV dark matter detection****Authors:** Jordan Smolinsky¹; Konstantin Matchev²; Wei Xue²; Yining You³¹ *UC Irvine*² *University of Florida (US)*³ *University of Florida***Corresponding Author:** youy@ufl.edu

The detection of low mass dark matter is under development with the advancement of experiment techniques. The superfluid helium-4 detector covers an extensive detection range from DM mass keV to GeV among the setups. I will present a complete theoretical framework for all processes within the superfluid to fill in the missing theory for sub-GeV DM detection. First, we use effective field theories to construct the interaction Lagrangian between quasi-particles. Second, we use a U(1) gauge spontaneous breaking and current element method to derive the interaction between test particles and quasi-particles. In the end, I will discuss relevant cross-sections and decay rates.

Higgs & Electroweak Physics / 194**Search for di-Higgs production with ATLAS experiment in the $b\bar{b}l\nu$ final state****Author:** Zhe Yang¹¹ *University of Michigan (US)***Corresponding Author:** zheya@umich.edu

A search for Higgs boson pair production in $b\bar{b}l+\text{MET}$ final state with the ATLAS experiment will be presented. The analysis uses the full Run-2 data-set (139fb-1) collected at the LHC in pp collisions at $\sqrt{s}=13\text{TeV}$. Di-Higgs boson production from the SM tri-Higgs-boson interaction and from BSM resonant decays are investigated with a final state containing two jets (one or two tagged as b-jets) and two leptons with opposite electric charge. Three different channels where one of the Higgs bosons decays via $H\rightarrow b\bar{b}$ and the other via $H\rightarrow WW^*/ZZ^*/\tau^+\tau^-$ are included as di-Higgs signals contributions in the analysis. A deep-learning neural network has been used for event selection to improve the ATLAS di-Higgs boson detection sensitivity. The expected upper limits on the cross-sections were investigated based on MC simulated events.

The AMAC ASIC for the ATLAS ITk silicon strip detector: design and verification**Author:** Sicong Lu¹¹ *University of Pennsylvania (US)***Corresponding Author:** sicong.lu@cern.ch

A new silicon-strip charged-particle tracking detector (ITk strips) is a major component of the future upgrade of the ATLAS experiment for the high-luminosity LHC. The Autonomous Monitoring and Control (AMAC) chip is an application-specific integrated circuit designed to monitor voltages, currents and temperatures on each ITk module, and to control power to the front-end electronics. The ASIC design has been tested by both simulation and in-situ testing of prototype chips. The high fluence of charged particles moving through the read-out electronics during operation in the HL-LHC presents a set of inevitable radiation hazards. Python-interfaced simulation sequences were developed to challenge the chip's response to both single-event upsets (SEU) and single-event transients (SET). I will present how we use the simulation framework to verify that the AMAC performs its required functions and to study the response to single-event errors. I will also show the results from probing prototype chips and describe the database used to store this information.

Theoretical Uncertainties in the Higgs Boson Pair Production in the $b\bar{b}\tau\tau$ Decay Channel**Author:** Jem Aizen Mendiola Guhit¹**Co-author:** Thomas Andrew Schwarz¹¹ *University of Michigan (US)***Corresponding Author:** jem.aizen.mendiola.guhit@cern.ch

Higgs boson pair production (HH) is one of the more interesting processes to study at the LHC, as it allows us to probe Higgs Boson self-coupling and associated parameters of the Higgs potential, as well as search for physics beyond the standard model. The $b\bar{b}\tau\tau$ final state is one of the most sensitive channels for HH studies due to an appreciable branching ratio, and a relatively clean background. In this talk, the methods used in calculating a few of the more important theoretical uncertainties associated with this analysis are presented - in particular, perturbative QCD (pQCD) calculations and Parton Showers for single Higgs backgrounds. From pQCD, three main sources of uncertainties come from (i) missing higher orders in the perturbative expansion from the partonic cross section, (ii) parton distribution functions and (iii) experimental determination of the strong coupling constant. These uncertainties associated with pQCD correspond to parton-level final states. Since the simulated samples also pass-through showering and hadronization generators that convert the parton cross section to a hadron level cross section, additional uncertainties occur in (i) modelling parton shower and hadronization through the algorithm or parameters and (ii) matrix element next-to-leading-order calculations.

Higgs & Electroweak Physics / 197**Searching for lepton-flavour-violating decays of the Higgs boson with the ATLAS detector****Author:** Michaela Mlynarikova¹¹ *Northern Illinois University (US)***Corresponding Author:** michaela.mlynarikova@cern.ch

The quest for lepton-flavor-violating processes at the LHC represents one of the key searches for new physics beyond the Standard Model (SM). We present a search for Higgs boson decays into a tau lepton and either an electron or a muon. The analysis uses data from proton-proton collisions at the LHC at $\sqrt{s} = 13$ TeV, collected by the ATLAS detector and corresponding to an integrated luminosity of 36.1 fb^{-1} . No significant excess of events was found over the SM expectation and upper limits at 95% CL were placed on the branching ratios $\mathcal{B}(H \rightarrow e\tau)$ and $\mathcal{B}(H \rightarrow \mu\tau)$ of 0.47% and 0.28%, respectively. We conclude with a brief overview of an ongoing analysis of a larger data set with more sophisticated techniques that is expected to yield improved results.

Search for di-jet resonances along with an isolated charged lepton at $\sqrt{s} = 13$ TeV p-p collision with the ATLAS detector

Author: Wasikul Islam¹

¹ *University of Wisconsin-Madison (US)*

Corresponding Author: wasikul.islam@cern.ch

A search for dijet resonances in events with identified leptons has been performed using full Run 2 data collected in $\sqrt{s}=13$ TeV collisions at $\sqrt{s}=13$ TeV by the ATLAS detector, corresponding to an integrated luminosity of 139 fb⁻¹. The dijet invariant-mass (m_{jj}) distribution from events with at least one isolated electron or muon was probed in the range of $0.22 < m_{jj} < 6.3$ TeV. The analysis probes much lower m_{jj} than traditional inclusive dijet searches and has been sensitive to a large range of new physics models in association with a final-state lepton. As no statistically significant deviation from the Standard Model background hypothesis was found, limits were set on contributions from generic gaussian signals and on various beyond the Standard Model scenarios including the Sequential Standard Model, a technicolor model, a charged Higgs boson model and a simplified Dark Matter model.

The structure of an electron and calculation the actual energy of that

Author: Gh. Saleh¹

Co-authors: M. J. Faraji¹; Reza Alizadeh¹

¹ *Saleh Research Centre*

Corresponding Author: postmaster@saleh-theory.com

Everything in the Universe has its own structure; every structure is in harmony with the others; solar system, Milky Way, black holes, other systems of star around, etc. Also, electron which is one of the main subatomic particles is no exception. We could find electron in two different states: ground or excited state. Regardless of how it gets excited, we realize that it wants to return to the ground state by the emission of a photon. Indeed, the excited electron is the birthplace of photon. Photons are generated by Electrons, and if we show that an Electron is also made of Photons; it would be obvious that Electron and the Photon have a common nature. In this paper, we are going to show that an electron is made of photons and we will explain how they gather together.

By explaining the structure of the electron, we are going to calculate the energy of the electron. The energy of an electron is the summation of stored energy and kinetic energy which in the various applications of electrons, they show their special effect. Sometimes we perceive the stored energy, and sometimes the kinetic energy.

ATLAS Search for Non-Pointing and Delayed Photons

Author: Devin Mahon¹

¹ *Columbia University (US)*

Corresponding Author: devinmahon@comcast.net

Searches for physics beyond the Standard Model (SM) at collider experiments—mostly focused on prompt signatures with high momentum and high missing transverse energy—have thus far produced no definitive evidence for such phenomena. But what if they have been looking in the wrong places? Just as long-lived particles exist in the SM, beyond the SM physics may too feature such particles. Here, a novel search for displaced photons is introduced, using 139 fb⁻¹ of *pp* collision data at center-of-mass energy $\sqrt{s} = 13$ TeV collected with the ATLAS detector. The search specifically targets the relatively unconstrained branching ratio of the Higgs boson to invisible particles, where there is still ample room for signatures featuring relatively soft photons and modest missing transverse energy. Exploiting the longitudinal segmentation and the excellent precision timing capabilities of the ATLAS detector's liquid argon electromagnetic calorimeter, the striking, smoking-gun signature of a displaced photon that both fails to point back to the interaction point and arrives significantly delayed can be employed as a powerful discrimination variable. The analysis strategy, including the entirely data-driven background estimation method and expected sensitivities, is presented in detail.

Reconstructing Electrons and Photons in the CMS ECAL using Graph Neural Networks.

Authors: Lindsey Gray¹; Simon Rothman²; Rajdeep Mohan Chatterjee²; Roger Rusack²

¹ *Fermi National Accelerator Lab. (US)*

² *University of Minnesota (US)*

Corresponding Author: srothman@wesleyan.edu

One of the key sub-detectors of the CMS experiment, located at the CERN Large Hadron collider, is the electromagnetic calorimeter (ECAL). This homogeneous calorimeter is designed to detect electrons and photons with energies from as low as 500 MeV up to 1 TeV. The ECAL is a homogeneous calorimeter consisting of ~76,000 scintillating crystals arranged around the collision point in an 8m long barrel that has a diameter of 3m and two endcaps, all within a 4T magnetic field. Electrons and photons are detected as showers that spread across many crystals due to the magnetic field and interactions with the detector material.

A multi-step procedure has been developed in order to reconstruct the energy of these particles from the energy deposits in the crystals of the ECAL. In the first step of this procedure a clustering algorithm is employed to gather the energies deposited around a “seed” crystal, which are above a certain threshold and subject to certain topological requirements to ensure that energy being clustered is not electronic noise and belongs to the showering electromagnetic particle. In the next step corrections are applied to this clustered energy in order to account for effects such as out of cluster energy deposits, energy losses upstream of the ECAL as well as in dead crystal and gaps in the ECAL, energy leakage, etc. In order to apply this correction a gradient boosted regression is trained using a detector simulation to correct the reconstructed energy of electrons and photons to their true energies. This regression uses several high level variables which describe the electromagnetic shower as its input features. This regression-based correction is crucial to ensure that electrons and

photons are reconstructed with the correct energy scale and with an optimal resolution, and consequently is a key ingredient for several precision measurements, such as the masses of the Higgs and W bosons. This necessarily implies that any improved algorithm would result in gains in these flagship measurements in CMS.

We have recently developed an updated energy regression correction using graph neural networks which uses only low level information of the electromagnetic shower as input features. The algorithm we have developed already shows an improved energy reconstruction performance as compared to the current legacy algorithm and the same has also been validated in collision data. Efforts are now underway to extend it to other use cases, for example, discriminating prompt electrons and photons from jets which can fake them. In this report we will present this novel machine learning based algorithm and the results obtained with it, using both simulated and collision data from the CMS experiment.

¹ *Oklahoma State University*

² *Max-Planck-Institut fuer Kernphysik, Heidelberg, Germany*

³ *Max-Planck-Institut für Kernphysik*

Corresponding Author: vipadma@okstate.edu

We have analyzed new contributions to the muon anomalous magnetic moment in a class of models that generates a naturally large transition magnetic moment for the neutrino (needed to explain the XENON1T electron recoil excess). These models are based on an approximate $SU(2)_H$ symmetry that suppresses the neutrino mass while allowing for a large neutrino transition magnetic moment. We have shown that the new scalars present in the theory with masses around 100 GeV can yield the right sign and magnitude for the muon $g-2$ which has been confirmed recently by the Fermilab collaboration. Such a correlation between muon $g-2$ and the neutrino magnetic moment is generic in models employing leptonic family symmetry to explain a naturally large neutrino magnetic moment. We have also outlined various other experimental tests of these models at colliders. Results will be presented.

Triggering long-lived particles (LLPs) at the first stage of the trigger system is very crucial in LLP searches to ensure that we do not miss them at the very beginning. The future High Luminosity runs of the Large Hadron Collider will have an increased number of pile-up events per bunch crossing. There will be major upgrades in hardware, firmware and software sides, like tracking at level-1 (L1). The L1 trigger menu will also be modified to cope with pile-up and maintain the sensitivity to physics processes. In our study we found that the usual level-1 triggers, mostly meant for triggering prompt particles, will not be very efficient for LLP searches in the 140 pile-up environment of HL-LHC, thus pointing to the need to include dedicated L1 triggers in the menu for LLPs. We consider the decay of the LLP into jets and develop dedicated jet triggers using the track information at L1 to select LLP events. We show in our work that these triggers give promising results in identifying LLP events with moderate trigger rates.

Higgs to two b's or not two b's: The measurement for a Standard Model Higgs boson, produced in association with a W or Z boson, decaying into a pair of b-quarks in pp collisions at 13 TeV with the ATLAS detector

Author: Amy Tee¹

¹ *University of Wisconsin Madison*

Corresponding Author: amy.tee@cern.ch

Following the discovery of the Higgs boson in 2012 by both the ATLAS and CMS experiments, a wealth of papers have been published concerning measurements or observations of the Higgs' decay modes. However, the most dominant decay mode, $H \rightarrow b\bar{b}$, proved to be an elusive and challenging search due to the low signal-to-background environment, and a diverse range of backgrounds arising from multiple Standard Model processes. The backgrounds include W +jets, Z +jets, and $t\bar{t}$ production amongst others. Measurements of the WH and ZH production, with the W or Z boson decaying into charged leptons (electrons or muons, including those produced from the leptonic decay of a tau lepton), in the $H \rightarrow b\bar{b}$ decay channel in pp collisions at 13 TeV, corresponding to an integrated luminosity of 139 fb^{-1} , with the ATLAS detector was performed. The production of a Higgs boson in association with a W or Z boson has been established with observed (expected) significances of 4.0 (4.1) and 5.3 (5.1) standard deviations, respectively.

Search for heavy resonances decaying into a W boson and a Higgs boson in final states with leptons and b-jets in 139 fb⁻¹ of pp collisions at sqrt(s)=13TeV with the ATLAS detector

Author: Makayla Vessella¹

Co-author: Carlo Dallapiccola¹

¹ *University of Massachusetts (US)*

Corresponding Author: makayla.vessella@cern.ch

This talk presents a search for a new resonance W' decaying into a W boson and a 125 GeV Higgs boson H in the $\ell^\pm \nu b \bar{b}$ final states, where $\ell = e, \mu, \text{ or } \tau$, using pp collision data at 13 TeV corresponding to an integrated luminosity of 139 fb⁻¹ collected by the ATLAS detector at LHC. The search considers the one-lepton channel, where an electron, muon, or leptonically decaying tau lepton is successfully reconstructed. Both resolved and merged regimes, as well as one and two b-tag regions, are employed to reconstruct the $H \rightarrow b\bar{b}$ decay across the range of W' masses. The search is conducted by examining the reconstructed invariant mass distributions of $W' \rightarrow WH$ candidates in the mass range from 400 GeV to 5 TeV. Upper limits are placed at the 95% confidence level on the production cross-section times branching fraction of heavy W' resonances in heavy-vector-triplet models.

Constraints on anomalous Higgs boson couplings to vector bosons and fermions in its production and decay using the four-lepton final state

Author: Heshy Roskes¹

¹ Johns Hopkins University (US)

Corresponding Author: jroskes1@jhu.edu

Studies of CP violation and anomalous couplings of the Higgs boson to vector bosons and fermions are presented. The data were acquired by the CMS experiment at the LHC and correspond to an integrated luminosity of 137 fb^{-1} at a proton-proton collision energy of 13 TeV. The kinematic effects in the Higgs boson's four-lepton decay $H \rightarrow 4\ell$ and its production in association with two jets, a vector boson, or top quarks are analyzed, using a full detector simulation and matrix element techniques to identify the production mechanisms and to increase sensitivity to the Higgs boson tensor structure of the interactions. A simultaneous measurement is performed of up to five Higgs boson couplings to electroweak vector bosons (HVV), two couplings to gluons (Hgg), and two couplings to top quarks (Htt). The CP measurement in the Htt interaction is combined with the recent measurement in the $H \rightarrow \gamma\gamma$ channel. The results are presented in the framework of anomalous couplings and are also interpreted in the framework of effective field theory, including the first study of CP properties of the Htt and effective Hgg couplings from a simultaneous analysis of the gluon fusion and top-associated processes. The results are consistent with the standard model of particle physics.

Call for Abstracts Search for pair production of vector-like quarks in the $Wb+X$ final state using the full Run 2 dataset of pp collisions at $\sqrt{s} = 13 \text{ TeV}$ from the ATLAS detector

Author: Evan Richard Van De Wall¹

¹ Oklahoma State University (US)

Corresponding Author: evan.richard.vandewall@cern.ch

Vector-like quarks (VLQ) are predicted in many extensions to the Standard Model (SM), especially those aimed at solving the hierarchy problem. Their vector-like nature allows them to extend the SM while still being compatible with electroweak sector measurements. In many models, VLQs decay to a SM boson and to a third-generation quark. Pair production of VLQ provides a model-independent method of searching due to the Quantum Chromodynamics production of the particles. This talk presents a search for pair production of vector-like top quarks that each decay into a SM W boson and a bottom quark, with one W boson decaying leptonically and the other decaying hadronically. The analysis takes advantage of boosted boson identification and data-driven correction of the dominant $t\bar{t}$ background prediction to improve sensitivity. Further, this analysis extends the previous analysis sensitivity by including the full 140 fb^{-1} dataset of pp collisions at $\sqrt{s} = 13 \text{ TeV}$ collected with the ATLAS detector.

Using Dropout to Capture Uncertainty: A Novel Application to B-tagging

Authors: Binbin Dong¹; Jeremy Robert Love²; Yiming Abulaiti²

¹ *Shanghai Jiao Tong University (CN)*

² *Argonne National Laboratory (US)*

Corresponding Author: binbin.dong@cern.ch

Deep learning techniques have gained tremendous attention from researchers in many fields, including particle physics. However such techniques typically do not capture model uncertainty. Bayesian models offer a solid framework to quantify the uncertainty, but they normally come with a high computational cost. A recent paper develops a new theoretical framework casting dropout in Neural Networks (NNs) as approximate Bayesian inference for Gaussian processes without changing either the models or the training.

In this talk, I will present how this method can be applied to evaluate multi-classification uncertainty using the Modified National Institute of Standards and Technology (MNIST) dataset. The results from evaluating will include both the model uncertainty, as well as uncertainties from systematic mis-modeling of the training data. I will also present preliminary results of this method applied to the ATLAS identification of jets coming from b-quarks with high momentum, and compare the difference in uncertainties between NNs trained on samples of low momentum only and those including high momentum jets.

Muon Momentum Estimation in ProtoDUNE Using Multiple Coulomb Scattering

Authors: Hunter Meyer¹; Thomas Jan Kutter²

¹ *Louisiana State University*

² *Louisiana State University (US)*

Corresponding Author: hmeyer5@lsu.edu

The Deep Underground Neutrino Experiment (DUNE) is a long baseline neutrino experiment using liquid argon detectors to study neutrino oscillations, proton decay, and other phenomena. The single-phase ProtoDUNE detector is a prototype of the DUNE far detector and is located in a charged particle test beam at CERN. It is critical to have accurate momentum estimation of charged particles for calibration and testing of the ProtoDUNE detector performance, as well for proper analysis of DUNE data. Charged particles passing through matter undergo multiple Coulomb scattering (MCS). MCS is momentum-dependent, allowing it to be used in muon momentum estimation while allowing for momentum estimation of muons exiting the detector, a key benefit of MCS over various other methods. We will present the status of the MCS analysis which was developed and evaluated using Monte Carlo simulations and discuss the bias and resolution of our momentum estimation method, as well as its dependencies on the detector resolution.

⁴ *Fermi National Accelerator Laboratory*

Corresponding Author: vspron@fnal.gov

The Mu2e experiment being constructed at Fermilab will search for indications of Charged Lepton Flavor Violation by measuring 105-MeV electrons emitted in conversions of negative muons into electrons in the nuclear field without emission of neutrinos. Mu2e-II is a proposed upgrade to the baseline Mu2e experiment to extend the reach by an order of magnitude. To enhance charged-pion production, the Mu2e-II upgrade will rely on a 100-kW 800-MeV proton beam from the dedicated linac accelerator complex PIP-II to be built at Fermilab. Mu2e-II will reach a higher sensitivity than the Mu2e baseline by increasing the rate of negative muons stopped in the detector's stopping target foils by a factor of about 10. Such sensitivity will allow Mu2e-II to reach New Physics mass scales up to $2 \cdot 10^4$ TeV. For Mu2e-II we are considering a novel conveyor target with spherical target elements moved through the beam path both mechanically and by a gas flow. We will discuss our recent advances in conceptual design R&D for a Mu2e-II target station, based on energy deposition and radiation damage simulations involving Monte-Carlo codes (MARS15, G4beamline, and FLUKA) as well as thermal and mechanical analyses to estimate the survivability of the system. The concurrent use of several simulation codes is intended to allow us to elucidate the specific systematic uncertainty inherent in simulations. Our simulations warrant that some other designs are less preferable and support our assessment of the target station's required working parameters and constraints. We show how thermal and mechanical analyses determine the choice of cooling scheme and prospective materials for the conveyor's spherical elements.

Higgs & Electroweak Physics / 215**Using the light: A search for vector boson fusion production of the $H(\rightarrow b\bar{b})\gamma$ final state at $\sqrt{s} = 13$ TeV with the ATLAS detector****Author:** Carolyn Gee¹¹ *University of California, Santa Cruz (US)***Corresponding Author:** carolyn.mei.gee@cern.ch

A search for the Standard Model Higgs boson produced in association with a high-energy photon is performed using 132 fb^{-1} of pp collision data at $\sqrt{s} = 13$ TeV collected with the ATLAS detector at the Large Hadron Collider. The vector boson fusion production mode of the Higgs boson is particularly powerful for studying the $H(\rightarrow b\bar{b})\gamma$ final state because the photon requirement greatly reduces the multijet background and because the Higgs boson decays primarily to bottom quark-antiquark pairs. Utilization of Monte Carlo, machine learning, and model fitting techniques resulted in a measured Higgs boson signal strength of 1.3 ± 1.0 relative to the Standard Model prediction. This correlates with an observed signal significance greater than background of 1.3 standard deviations, compared to 1.0 standard deviations expected.

Neutrinos / 216**Search for low-energy nuclear recoil in XENON1T****Authors:** Fei Gao¹; Zihao Xu¹; Knut Moraa¹; Joseph Howlett¹¹ *Columbia University***Corresponding Author:** zx2281@columbia.edu

The XENON collaboration has recently published results lowering the energy threshold to search for nuclear recoils produced by solar ^8B neutrinos using a 0.6 tonne-year exposure with the XENON1T detector. Due to the low energy threshold, a number of novel techniques are required to reduce the consequent increase in backgrounds. No significant ^8B neutrino-like excess is found after unblinding. New upper limits are placed on the dark matter-nucleus cross section for dark matter masses as low as $3\text{ GeV}/c^2$, as well as on a model of non-standard neutrino interactions. This talk will present the techniques used to lower backgrounds and to validate signal and background models.

Beyond Standard Model / 217**Search for Gluino-Mediated Stop Pair Production in Events with b-jets and Large Missing Transverse Momentum Collected with the ATLAS Detector**

Author: Egor Antipov¹

¹ *Oklahoma State University (US)*

Corresponding Author: egor.antipov@cern.ch

A search for supersymmetry involving the pair production of gluinos decaying via stop quarks into the lightest neutralino $\tilde{\chi}_1^0$ is reported. It uses LHC pp collision data at $\sqrt{s} = 13 \text{ TeV}$ with an integrated luminosity of 139 fb^{-1} collected with the ATLAS detector in 2015-2018. The search is performed in events containing large missing transverse momentum and several energetic jets, at least three of which must be identified as originating from b-quarks. The analysis is done in two final states, one of which is required to have at least one charged lepton (electron or muon), and the second one is required the veto on leptons. Expected exclusion limit for gluino and neutralino masses is evaluated using simplified signal model. It is found to be 800 GeV and below for neutralino masses with gluino masses of less than 2275 GeV at the 95% confidence level.

Readout Tests of the ATLAS Detector's ITk Pixel System Toward the HL-LHC Upgrade

Author: Egor Antipov¹

¹ *Oklahoma State University (US)*

Corresponding Author: egor.antipov@cern.ch

Data acquisition (DAQ) tests of the RD53a single chip cards (SCC) using Yet Another Rapid Readout (YARR), Front-End Link eXchange (FELIX) and Reconfigurable Cluster Element (RCE) readout systems are performed. Test stand for the DAQ tests of RD53a SCC was assembled at the SLAC National Accelerator Laboratory. YARR is the system developed for readout of up to 4 SCC or one quad module. It is widely used by universities and labs. FELIX system is designed to readout multiple modules; it is selected as the baseline readout system of the prototypes after the system integration. RCE is a System-on-Chip based readout system developed at SLAC, that is the principal data transmission qualification platform which also serves early module tests and large structure readout. DAQ tests of the three readout systems are required to proceed further with the ITk Pixel System upgrade toward the High Luminosity LHC Upgrade of the ATLAS detector. Comparison of results obtained with YARR, FELIX and RCE readout systems is presented.

Celestial-Body Focused Dark Matter Annihilation Throughout the Galaxy

Authors: Natalia Toro¹; Rebecca Leane²; payel mukhopadhyay³; Tim Linden^{None}

¹ SLAC² Massachusetts Institute of Technology³ Stanford University**Corresponding Author:** payelmuk@stanford.edu

Indirect detection experiments typically measure the flux of annihilating dark matter (DM) particles propagating freely through galactic halos. We consider a new scenario where celestial bodies “focus” DM annihilation events, increasing the efficiency of halo annihilation. In this setup, DM is first captured by celestial bodies, such as neutron stars or brown dwarfs, and then annihilates within them. If DM annihilates to sufficiently long-lived particles, they can escape and subsequently decay into detectable radiation. This produces a distinctive annihilation morphology, which scales as the product of the DM and celestial body densities, rather than as DM density squared. We show that this signal can dominate over the halo annihilation rate in γ -ray observations in both the Milky Way Galactic center and globular clusters. We use Fermi and H.E.S.S. data to constrain the DM-nucleon scattering cross section, setting powerful new limits down to $\sim 10^{-39} \text{ cm}^2$ for sub-GeV DM using brown dwarfs, which is up to nine orders of magnitude stronger than existing limits. We demonstrate that neutron stars can set limits for TeV-scale DM down to about 10^{-47} cm^2 .

Particle Detectors / 220**The HCCStar ASIC for the ATLAS ITk silicon strip detector: design and verification****Author:** Benjamin John Rosser¹¹ University of Pennsylvania (US)**Corresponding Author:** bjr@sas.upenn.edu

The Hybrid Controller Chip (HCC) is an application specific integrated circuit that's part of the front-end electronics for the new ATLAS Inner Tracker Strip detector, which will be installed as part of the High Luminosity LHC upgrade program. A prototype of the HCC was produced and tested in 2018 and 2019, and the production version is currently being prepared. The HCC must read out clustered hit data from the strip tracker at a high rate while simultaneously surviving exposure to large amounts of ionizing radiation. This radiation can interfere with the normal operations of the circuit by causing logic and memory errors known as single event effects, which can cause bits to invert and data to become corrupted. This talk will discuss work to verify the correctness of the digital logic of the production HCC, with a particular focus on simulation of these single event effects to assess how well the design is protected against radiation before submitting the chip.

Lepton Flavor and Precision Measurements / 221**A Familon Search Using the Mu2e Calibration Run****Authors:** David Koltick¹; Pavel Murat²; Shihua Huang¹

¹ *Purdue University*² *Fermi National Accelerator Lab. (US)***Corresponding Author:** huan1151@purdue.edu

One major puzzle in particle physics is the replicated lepton families. There appears to be a ‘family symmetry’ which prevents charged lepton flavor violating (CLFV) processes. If a continuous global lepton family symmetry exists, it leads to associated Goldstone bosons, ‘familons’, through spontaneous symmetry breaking. The familon can acquire mass if this symmetry is also explicitly broken. Such family symmetry can be tested by searching for the beyond-standard-model (BSM) muon decay,

$$\mu^\pm \rightarrow f + e^\pm$$

For μ -decay at rest, the signal would be a mono-energetic electron with its energy determined by the familon mass. Various experiments have established branching ratio limits from $10^{-5} \sim 10^{-6}$ for $\mu^+ \rightarrow f + e^+$, over the familon mass range.

Mu2e has an opportunity to search for familon production using data from a short momentum calibration run at the experiment’s start. The goal of the run is a high precision measurement of the (positron) Michel spectrum, to study both the momentum scale and the momentum resolution of the detector, near the decay positron’s kinematic endpoint ($m_\mu c/2 \sim 53$ MeV/c). This same study will have acceptance for decay familons in the momentum range [35-53] MeV/c.

A familon signal would appear as a line in the reconstructed Michel spectrum. A number of changes to the standard Mu2e running conditions need to be implemented to accomplish the familon search. Assuming the proton beam intensity is reduced to 1/10 nominal, an averaged luminosity of 2.5×10^8 μ^+ stops per real second allows, in 1-day of continuous data-taking, to surpass existing branching ratio limits by ~ 2 orders of magnitude. However, such a beam intensity at 50% magnetic field requires the charged particle tracker to operate outside its Mu2e parameter set, which is now under-study. Nonetheless, even if the proton beam intensity is reduced to 1/1000 nominal, in 1-day of data collection the existing branching ratio limits will be surpassed by an order of magnitude. In both cases limits are set over the familon mass range from [0-40] MeV/c².

Algorithm design and expected performance for ATLAS Run-3 Level-1 calorimeter trigger system

Authors: Ava Anne Myers¹; Tae Min Hong¹¹ *University of Pittsburgh (US)***Corresponding Author:** ava.anne.myers@cern.ch

In Run 3 of the LHC (2022-2024), the Level-1 trigger system of the ATLAS experiment will introduce three feature extractors (FEX): eFEX for electron/photon, jFEX for jets/MET, and gFEX for global quantities. The increased calorimeter granularity is useful for all physics channels that deposit energy in the calorimeter, from high-bandwidth items like electrons to MET (missing transverse momentum). An overview of the hardware implementation will be discussed. Details of the algorithm design will be presented, along with the projected performance for electron/photon, jet, and MET triggers.

Dark Matter Search Results from DAMIC at SNOLAB**Author:** Alexander Piers¹¹ *University of Washington***Corresponding Author:** apiers@uw.edu

The DAMIC experiment at SNOLAB uses thick, fully-depleted, scientific grade charge-coupled devices (CCDs) to search for the interactions between proposed dark matter particles in the galactic halo and the ordinary silicon atoms in the detector. DAMIC CCDs operate with an extremely low instrumental noise and dark current, making them particularly sensitive to ionization signals expected from low-mass dark matter particles. Throughout 2017-18, DAMIC has collected data with an array of seven CCDs (40-gram target) installed in a low radiation environment in the SNOLAB underground laboratory. This talk will focus on the recent dark matter search results from DAMIC. We will present the search methodology and results from an 11 kg day exposure WIMP search, including the strictest limit on the WIMP-nucleon scattering cross section for a silicon target for $m_\chi < 9 \text{ GeV } c^{-2}$. Additionally, we will discuss recent limits on light dark matter that could interact with the electrons of the silicon atoms.

Search for invisible decays of the Higgs boson and for dark matter with the ATLAS detector**Author:** Chuanshun Wei¹¹ *University of Michigan (US)/University of Science and Technology of China (CN)***Corresponding Author:** chuanshun.wei@cern.ch

The total decay width of the Higgs has not yet been constrained precisely, which allows for up to 11% of the branching fraction to be from beyond the standard model decays, so the Higgs Decay represents one possible way for Dark Matter(DM) searches. This talk will discuss the search for invisibly decaying Higgs boson or DM particles produced in association with a Z boson that decays into an electron or muon pair in pp collisions at $\sqrt{s} = 13 \text{ TeV}$ corresponding to an integrated luminosity of 139 fb^{-1} collected with the ATLAS detector during the 2015-2018. Z+Higgs boson(ZH), Mono-Z spin-1 simplified models and 2HDM+a models are involved in this analysis, and the observed events number is consistent with the Standard Model prediction. The upper limit on the branching ratio for the Higgs to invisible particles is also updated.

Higgs & Electroweak Physics / 225**Studies of $t\bar{t}HH$ with the CMS Detector****Author:** Wei Wei¹¹ *University of California Davis (US)***Corresponding Author:** wei.w@cern.ch

Precision measurements of Higgs boson couplings to SM particles is a central task at the LHC today and for the future HL-LHC. Due to the $\sim O(\text{nb})$ $t\bar{t}$ cross section and large Yukawa coupling, measurements of the interaction of the Higgs with top quarks is particularly compelling. The $t\bar{t}HH$ signal can be used to probe this coupling and also provides a direct measurement of trilinear Higgs self-coupling. We search for $t\bar{t}HH$ production with the CMS detector at the LHC both in the SM and in an EFT model. In SM we look for semi-leptonic decay of the top-quark pair and the decay of both Higgs bosons to b-quarks using full Run 2 data. We also develop a simplified EFT model to study this signal independently of $t\bar{t}H$, in which 6D and 8D gauge-invariant operators are included to modify $t\bar{t}HH$ while keeping $t\bar{t}H$ unchanged at tree level. In this model, which includes a BSM $t\bar{t}HH$ vertex, Higgs bosons are produced at higher p_T compared with those from SM production. Due to the resulting Lorentz boost, we observe an enhancement around the Higgs mass in the single b-jet mass spectrum.

Gravity and Gravitational Waves / 226**A possible mass distribution of primordial black holes implied by LIGO-Virgo****Author:** Heling Deng¹¹ *Arizona State University***Corresponding Author:** dengheling@gmail.com

The LIGO-Virgo Collaboration has so far detected around 90 black holes, some of which have masses larger than what were expected from the collapse of stars. The mass distribution of LIGO-Virgo black holes appears to have a peak at $\sim 30M_\odot$ and two tails on the ends. By assuming that they all have a primordial origin, we analyze the GWTC-1 (O1&O2) and GWTC-2 (O3a) datasets by performing maximum likelihood estimation on a broken power law mass function $f(m)$, with the result $f \propto m^{1.2}$ for $m < 35M_\odot$ and $f \propto m^{-4}$ for $m > 35M_\odot$. This appears to behave better than the popular log-normal mass function. Surprisingly, such a simple and unique distribution can be realized in our previously proposed mechanism of PBH formation, where the black holes are formed by vacuum bubbles that nucleate during inflation via quantum tunneling. Moreover, this mass distribution can also provide an explanation for supermassive black holes formed at high redshifts.

FPGA filter for fast tracking in the ATLAS HL-LHC trigger

Author: William Kalderon¹

¹ *Brookhaven National Laboratory (US)*

Corresponding Author: william.kalderon@cern.ch

This talk introduces and shows the simulated performance of an FPGA-based technique to improve fast track finding in the ATLAS trigger. A fast track trigger is being developed in ATLAS for the High Luminosity upgrade of the Large Hadron Collider (HL-LHC), the goal of which is to provide the high-level trigger with full-scan tracking at 100 kHz in the high pile-up conditions of the HL-LHC. Options under development for achieving this include a method based on matching detector hits to pattern banks of simulated tracks stored in a custom made Associative Memory ASIC (Hardware Track Trigger, “HTT”) and one using the Hough transform (whereby detector hits are mapped onto a 2D parameter space with one parameter related to the transverse momentum and one to the initial track direction) on FPGAs (“Hough”).

Both of these methods can benefit from a pre-filtering step, to reduce the number of hit clusters that need to be considered and hence reduce the overall system size and/or power consumption, by examining pairs of clusters in adjacent strip detector layers (or lack thereof). This stub-filtering was first investigated by CMS but has been unexplored in ATLAS until now, and we will show the reduction in throughput enabled along with the performance impact on both HTT and Hough systems of track finding, as well as estimates of resource usage.

Non-Abelian Vector Dark Matter and Lepton Anomalous Magnetic Moments

Author: shaikh saad¹

¹ *University of Basel*

Corresponding Author: shaikh.saad@okstate.edu

A non-Abelian $SU(2)_X$ gauge extension of the Standard Model is considered under which leptons carry non-trivial charge. Gauge anomaly cancellation requires additional vectorlike fermions, which along with neutral vector bosons that play the role of Dark Matter correct the muon and the electron anomalous magnetic moments as preferred by experiments. When Collider bounds, electroweak precision data, dark matter relic abundance, and lepton $g - 2$ are considered, the model is viable only within a narrow range of parameter space that corresponds to 1-3 TeV mass for the dark matter.

In this talk, we will introduce a technique to train neural networks into being good event variables, which are useful to an analysis over a range of values for the unknown parameters of a model.

We will use our technique to learn event variables for several common event topologies studied in colliders. We will demonstrate that the networks trained using our technique can mimic powerful, previously known event variables like invariant mass, transverse mass, and MT2.

We will describe how the machine learned event variables can go beyond the hand-derived event variables in terms of sensitivity, while retaining several attractive properties of event variables, including the robustness they offer against unknown modeling errors.

The Cherenkov Telescope Array: probing fundamental Physics with the next-generation observatory for very-high-energy gamma rays

Author: Massimo Capasso¹

¹ *Barnard College, Columbia University*

Corresponding Author: capasso@nevis.columbia.edu

The Cherenkov Telescope Array (CTA) is the next-generation ground-based observatory for very-high-energy (VHE, $E > 100$ GeV) gamma-rays. It will consist of more than 100 imaging atmospheric Cherenkov telescopes (IACTs) divided between two arrays in the Northern and the Southern hemispheres. Featuring telescopes with different sizes, it will provide coverage of the whole sky over a wide energy range, between ~ 20 GeV and ~ 300 TeV.

The science topics that CTA wants to address can be divided into three main themes: understanding the origin and role of relativistic cosmic particles, probing extreme environments such as neutron stars and black holes, and exploring frontiers in Physics. Physics frontier topics to be studied with CTA include the particle nature and constituents of Dark Matter in indirect searches through gamma rays, tests of Lorentz invariance using gamma-ray propagation and probes of cosmology. U.S. scientists have led an international collaboration to build and operate a prototype 9.7-m IACT for CTA, the prototype Schwarzschild-Couder Telescope (pSCT), an innovative design proposed as a telescope candidate for CTA. The pSCT features an innovative dual-mirror design and a camera with state-of-the-art silicon photomultiplier detectors. The pSCT has recently successfully detected the Crab Nebula with 8.6 standard deviations utilizing a partially-equipped camera. A funded upgrade of the pSCT focal plane sensors and electronics is currently ongoing, which will bring the total number of channels from 1600 to 11328 and the telescope field of view from about 2.7° to 8° .

In this talk, I will introduce the CTA project with particular focus on its potential to explore frontiers in Physics as well as describe the proposed U.S. participation.

Photophilic hadronic axion from heavy magnetic monopoles

Author: Anton Sokolov¹

Co-author: Andreas Ringwald²

¹ DESY

² Deutsches Elektronen-Synchrotron DESY

Corresponding Author: anton.sokolov@desy.de

We propose a model for the QCD axion which is realized through a coupling of the Peccei-Quinn scalar field to magnetically charged fermions at high energies. We show that the axion of this model solves the strong CP problem and then integrate out heavy magnetic monopoles using the Schwinger proper time method. We find that the model discussed yields axion couplings to the Standard Model which are drastically different from the ones calculated within the KSVZ/DFSZ-type models, so that large part of the corresponding parameter space can be probed by various projected experiments. Moreover, the axion we introduce is consistent with the astrophysical hints suggested both by anomalous TeV-transparency of the Universe and by excessive cooling of horizontal branch stars in globular clusters. We argue that the leading term for the cosmic axion abundance is not changed compared to the conventional pre-inflationary QCD axion case for axion decay constant $f_a > 10^{12}$ GeV.

Study of inclusive Higgs-boson production at high transverse momentum in the $H \rightarrow b\bar{b}$ decay mode with the ATLAS detector

Author: Andrea Sciandra¹

¹ *University of California, Santa Cruz (US)*

Corresponding Author: andrea.sciandra@cern.ch

The ever-growing interest into high-energy production of the Higgs boson, motivated by an enhanced sensitivity to New Physics scenarios, pushes the development of experimental techniques for the reconstruction of boosted decay products from the Higgs-boson hadronic decays.

This talk will discuss recent studies of inclusive Higgs-boson production with sizable transverse momentum decaying to a $b\bar{b}$ quark pair (ATLAS-CONF-2021-010). The analyzed data were recorded with the ATLAS detector in proton-proton collisions with a center-of-mass energy of $\sqrt{s} = 13$ TeV at the Large Hadron Collider between 2015 and 2018, corresponding to an integrated luminosity of 136 fb^{-1} .

Higgs bosons decaying to $b\bar{b}$ are reconstructed as single large-radius jets and identified by the experimental signature of two b -hadron decays. The analysis takes advantage of an analytical model for the description of the multi-jet background, and combines multiple regions rich in Higgs-boson signal and specific background signatures. The experimental techniques are validated in the same kinematic regime using the $Z \rightarrow b\bar{b}$ process.

For Higgs-boson production at transverse momenta above 450 GeV, the production cross section is found to be $13 \pm 57(\text{stat.}) \pm 22(\text{syst.}) \pm 3(\text{theo.}) \text{ fb}$. The differential cross section 95% confidence level upper limits as a function of Higgs boson transverse momentum are $\sigma_H(300 < p_T^H < 450 \text{ GeV}) < 2.8 \text{ pb}$, $\sigma_H(450 < p_T^H < 650 \text{ GeV}) < 91 \text{ fb}$, $\sigma_H(p_T^H > 650 \text{ GeV}) < 40.5 \text{ fb}$, and $\sigma_H(p_T^H > 1 \text{ TeV}) < 10.3 \text{ fb}$. Evidence for the production of $Z \rightarrow b\bar{b}$ with $p_T^Z > 650 \text{ GeV}$ is obtained. All results are consistent with the Standard Model predictions.

Stellar Shocks From Dark Matter

Authors: Anirban Das¹; Sebastian Ellis²; Philip Schuster^{None}; Kevin Zhou³

¹ *SLAC National Accelerator Laboratory*

² *SLAC National Accelerator Laboratory (US)*

³ *Stanford University*

Corresponding Author: knzhou@stanford.edu

Macroscopic dark matter is almost unconstrained over a wide “asteroid-like” mass range, where it could scatter on baryonic matter with geometric cross section. We show that when such an object travels through a star, it produces shock waves which reach the stellar surface, leading to a distinctive transient optical, UV and X-ray emission. This signature can be searched for on a variety of stellar types and locations. In a dense globular cluster, such events occur far more often than flare backgrounds, and an existing UV telescope could probe orders of magnitude in dark matter mass in one week of dedicated observation.

Low-mass primordial black holes as the dark matter candidateAuthor: Ranjan Laha¹¹ *Indian Institute of science (IN)*

Corresponding Author: ranjan.laha@cern.ch

Primordial black holes (PBHs), possibly formed via gravitational collapse of large density perturbations in the very early universe, are one of the earliest proposed and viable dark matter (DM) candidates. Recent studies indicate that PBHs can make up a large or even entire fraction of the present day DM density for a wide range of masses. Ultralight PBHs in the mass range of 10^{15} - 10^{17} g, emit particles through Hawking radiation, and can be probed via observations of those emitted particles in various detectors. In this talk, I will discuss how the observations of the 511 keV gamma ray line and continuum gamma-rays set some of the most stringent exclusion limits on the DM fraction of ultralight PBHs. I will also demonstrate how measurements of low-energy photons from the Galactic Center by the imminent telescopes such as AMEGO can probe the DM fraction of PBHs into a completely unexplored mass window.

Gravitational corrections to two-loop beta function in quantum electrodynamicsAuthors: Adilson Silva¹; André Lehum²; Huan Souza²; Carlos Senise³; Leandro Bevilaqua⁴; Marco Dias³¹ *University of São Paulo*² *Federal University of Pará*³ *Federal University of São Paulo*⁴ *Federal University of Rio Grande do Norte*

Corresponding Author: huan.souza@icen.ufpa.br

The quantization of Einstein's general relativity leads to a nonrenormalizable quantum field theory. However, the potential harm of nonrenormalizability, can be overcome in the effective field theory (EFT) framework, where there is an unambiguous way to define a well behaved and reliable quantum theory of gravitation, if only we agree to restrict ourselves to low energies compared to the Planck scale. Although the effective field theory of gravitation is perfectly well-defined as a quantum field theory, some subtleties arise from its nonrenormalizability, such as the use of the renormalization group equations, as illustrated by the controversy involving the gravitational corrections to the beta function of gauge theories. In 2005, Robinson and Wilczek announced their conclusion that gravity contributes with a negative term to the beta function of the gauge coupling, meaning that quantum gravity could make gauge theories asymptotically free. This result was soon contested. It was shown that the claimed gravitational correction is gauge dependent, and a lot of subsequent research on the subject followed with varying conclusions. In this work we use the framework of effective field theory to couple Einstein's gravity to quantum electrodynamics and determine the gravitational corrections to the two-loop beta function of the electric charge. Our results indicate that gravitational corrections do not alter the running behavior of the electric charge, on the contrary, we observe that it gives a positive contribution to the beta function, making the electric charge grow faster.

Thermal and electrical performance of the ATLAS strips module testing setup

Author: Punit Sharma¹

¹ *University of Iowa (US)*

Corresponding Author: punit.sharma@cern.ch

The inner tracking detector of the ATLAS experiment at CERN is currently preparing for an upgrade to operate in the high Luminosity LHC, scheduled to start in 2027. A complete replacement of the existing Inner Detector of ATLAS is required to cope with the expected radiation damage. The all-silicon Inner Tracker (ITk) design under construction composes a mixture of Pixel and Strips layers. At the core of the strips detector barrel are the staves, which host 28 silicon modules. A thorough characterization of the modules before the assembly on each stave is critical; therefore, each module undergoes electrical and thermal quality control (QC) testing between module production and stave assembly. All the modules must be thermal cycled ten times between -35C and +40C. This talk will show the thermal and electrical performance of the US testing setup, focusing on the difficulties encountered to meet the QC requirements. It will also give an overview of the results obtained by analyzing the first batch of produced modules.

The high collision energy and luminosity of the LHC allow studying jets and hadronically-decaying tau leptons at extreme energies with the ATLAS detector. These signatures lead to topologies with charged particles, which are reconstructed as tracks with the ATLAS inner detector, at an angular separation smaller than the size of a charge cluster in the ATLAS pixel detector, forming merged pixel clusters. In the presence of these merged clusters, the track reconstruction efficiency is reduced, as hits can no longer be uniquely assigned to individual tracks. Well-defined tracks are very important for many analyses. To partially recover the track reconstruction efficiency loss, a neural network (NN) based approach was adopted in the ATLAS pixel detector in 2011 to split the merged clusters by estimating particle hit multiplicity, hit positions, and associated uncertainties. An improved algorithm based on Mixture Density Networks (MDN) shows promising performance and will be used in the ATLAS inner detector track reconstruction in Run-3. An overview of the MDN algorithm and its performance will be highlighted in this presentation. This talk will also show a performance comparison between the Run-2 NN and Run-3 MDN.

Axion-like Particle Searches at Rare Nuclear Isotope Accelerator Facilities

Authors: Doojin Kim¹; Jae Yu²; K.C. Kong³; Wooyoung Jang⁴

¹ *Texas A & M University (US)*

² *University of Texas at Arlington (US)*

³ *University of Kansas*

⁴ *Kyungpook National University (KR)*

Corresponding Author: doojin.kim@cern.ch

Rare nuclear isotope accelerator facilities provide high-flux proton beams to produce a large number of rare nuclear isotopes. The high-intensity nature of their beams enables investigating dark-sector particles including axion-like particles (ALPs). In this talk, we will discuss detection prospects of ALP, using its coupling to Standard Model photons, in DAMSA (Dump-produced Aboriginal Matter Searches at Accelerator), a proposed experiment at RAON (Rare isotope Accelerator complex for ONline experiment) constructed in Korea. DAMSA features the close proximity of its detector to the target (i.e., ALP production dump) and a high-intensity proton beam, and as a result, DAMSA is capable of probing a high-mass region of ALP parameter space, which has never been explored by the existing experiments, and the region below the so-called “cosmological triangle”. While the neutrino-induced backgrounds produced in the target and subsequently entering the detector are greatly suppressed thanks to the low 600-MeV proton beam energy, the mitigation of huge beam-related neutron backgrounds is rather challenging. We argue that they can be significantly suppressed with a high-capability detector system and hence the proposed ALP searches are feasible, inspiring other nuclear isotope accelerator facilities to pursue similar physics opportunities.

The LDMX Trigger Scintillator system

Authors: Andrew James Whitbeck¹; Niramay Gogate²

¹ *Texas Tech University (US)*

² *Texas Tech University*

Corresponding Author: niramay.gogate@cern.ch

New theoretical developments have motivated “hidden sector” dark matter with mass below the proton mass. The Light Dark Matter Experiment (LDMX) will use an electron beam to produce dark matter in fixed-target collisions. A low current, high repetition rate (37.2MHz) electron beam extracted from SLAC’s LCLS-II will provide LDMX with sufficient luminosity to explore many dark matter candidates. Using a novel detector design, LDMX is expected to definitively search for thermal relic dark matter with masses between 1 MeV and several hundred MeV. The LDMX trigger system will reduce the high repetition rate of 37.2MHz down to about 5 kHz. In order to identify signal events, a missing energy trigger will be used that will rely on knowledge of the number of incoming electrons. To determine the electron multiplicity, arrays of fast scintillators will be used. A strategy for the missing energy trigger will be described. An overview of the LDMX trigger scintillators and the current status of simulation studies will be presented.

Search for Resonant and Non-Resonant VHH Production

Authors: Jianming Qian¹; Lianliang Ma²; Matthew Henry Klein³; Nicholas Graves Kyriacou³; Nikolaos Rompotis⁴; Tong Li²; Zhongyukun Xu²

¹ *University of Michigan*² *Shandong University (CN)*³ *University of Michigan (US)*⁴ *University of Liverpool (UK)***Corresponding Author:** nkyriaco@umich.edu

After the Higgs Boson, with a mass of 125 GeV, was discovered in 2012, studies of single Higgs boson production have largely confirmed that this particle has similar properties to the Higgs boson predicted by the Standard Model (SM). However, it is clear that physics beyond the SM is required to explain many observed phenomena in nature, and there remains the possibility that the Higgs Boson can act as a portal for BSM physics. Studies of Higgs boson pair production (HH) represent the next crucial step to constraining the Higgs sector and allow for the chance to explore resonant HH production as well as refining measurements of the Higgs boson self-coupling. While previous searches have focused on the HH production in the gluon-gluon and vector-boson fusion modes, this analysis documents a new search, with 136 fb^{-1} of pp collisions at $\sqrt{s} = 13 \text{ TeV}$ collected by ATLAS in LHC Run 2, for both resonant and non-resonant HH production in association with a vector boson (VHH). Three different channels are considered, corresponding to either $ZllHH$, $Z\nu\nu HH$, or $Wl\nu HH$, in order to have good coverage over the different final states. Only $H \rightarrow b\bar{b}$ is considered for simplicity and for the sake of high-statistics. The analysis benefits from small backgrounds and attempts to set limits for the first time on VHH production. Analysis techniques and expected significance will be presented.

Self-interacting dark matter from late decays and the H0 tension

Authors: Andrzej Hryczuk¹; Krzysztof Jodkowski²¹ *National Centre for Nuclear Research, Poland*² *National Centre for Nuclear Research***Corresponding Author:** krzysztof.jodkowski@ncbj.gov.pl

I will discuss dark matter production mechanism based on decays of a messenger WIMP-like state into a pair of dark matter particles that are self-interacting via exchange of a light, stable mediator. A natural by-product of this mechanism is a possibility of a late time transition to subdominant dark radiation component which increases the present-day Hubble rate. Simple realization of the proposed mechanism was studied in a Higgs portal dark matter model. We found a significant region of the parameter space that leads to a mild relaxation of the Hubble tension while simultaneously having the potential of addressing small-scale structure problems of Λ CDM.

Using Photosensitive Dopants to Enhance Large LArTPC Performance

Author: Joseph Zennaro¹

Co-authors: Andrew Mastbaum¹; Fernanda Psihas¹

¹ *Fermi National Accelerator Laboratory*

Corresponding Author: jaz8600@fnal.gov

A challenge in large LArTPCs is efficient photon collection for low energy, MeV-scale, deposits. Past studies have demonstrated that augmenting traditional ionization-based calorimetry with information from the scintillation signals can greatly improve the precision of measurements of energy deposited. We propose the use of photosensitive dopants to efficiently convert the scintillation signals of the liquid argon directly into ionization signals. This could enable the collection of more than 40% of all the scintillation information, a considerable improvement over conventional light collection solutions. We will discuss the implications this can have on LArTPC physics programs, what hints of performance improvements we can gather from past studies, and what R&D we envision are needed to establish using these dopants in large LArTPCs.

Search for top squark production in fully-hadronic final states in proton-proton collisions at $\sqrt{s}=13$ TeV

Author: Anna Henckel Merritt¹

Co-author: CMS Collaboration

¹ *University of Illinois at Chicago (US)*

Corresponding Author: anna.louise.henckel@cern.ch

A search for production of the supersymmetric partners of the top quark, top squarks, is presented. The search is based on proton-proton collision events containing multiple jets, no leptons, and large transverse momentum imbalance. The data were collected with the CMS detector at the CERN LHC at a center-of-mass energy of 13 TeV, and correspond to an integrated luminosity of 137 fb⁻¹. The targeted signal production scenarios are direct and gluino-mediated top squark production, including scenarios in which the top squark and neutralino masses are nearly degenerate. The search utilizes novel algorithms based on deep neural networks that identify hadronically decaying top quarks and W bosons, which are expected in many of the targeted signal models. No statistically significant excess of events is observed relative to the expectation from the standard model, and limits on the top squark production cross section are obtained in the context of simplified supersymmetric models for various production and decay modes.

Yukawa couplings from magnetized tori

Author: Shreya Shukla^{None}

Corresponding Author: sshukla4@uci.edu

One of the current problems of the Standard Model is that it does not predict the parameters of the flavor sector, e.g. mixing angles and CP phases need to be adjusted by hand. Recently, a new approach to address this problem has been to assume that Yukawa couplings are modular forms which give rise to a modular flavor symmetry in the Lagrangian. The two main ways to proceed have been to either impose the modular symmetry, or to derive it from e.g. a compactified torus. In this work, using the latter approach, we obtain a simplified version of Yukawa couplings, which are given by the overlap integral of the Dirac zero-mode wavefunctions. Using Euler's Theorem, we derive closed form analytic expressions for these Yukawa couplings that are valid for arbitrary magnetic flux parameters. This form is not only simple, but also has the advantage of making the modular transformations of Yukawa coupling more transparent.

Axion-like Particle Searches in the Laboratory

Author: Adrian Raphael Thompson¹

¹ *Texas A & M University*

Corresponding Author: thompson@tamu.edu

Axion-like particles (ALPs) provide a promising direction in the search for new physics, while a wide range of models incorporate ALPs. We point out that neutrino and dark matter experiments, such as DUNE, CCM, possess competitive sensitivity to ALP signals. High-intensity proton beams can not only produce copious amounts of neutrinos, but also cascade photons that are created from charged particle showers stopping in the target. Therefore, ALPs interacting with photons can be produced (often energetically) with high intensity via the Primakoff effect $\gamma \rightarrow \gamma \gamma$ and then leave their signatures via inverse Primakoff scattering or decays to photon pairs, $\gamma \rightarrow \gamma \gamma$. The proton beam may also induce an electron flux, which, together with the cascade photons, can produce ALPs via their couplings to electrons through bremsstrahlung-like and compton-like processes. Through this coupling, ALP detection via decays to $\gamma + \gamma$ and inverse compton scattering $\gamma \rightarrow \gamma \gamma$ are also possible.

The Large Hadron Collider (LHC) will soon undergo an upgrade, referred to as the High-Luminosity LHC (HL-LHC), which will increase the instantaneous luminosity beyond the LHC's design value. The ATLAS experiment is upgrading the innermost portion of the detector to the ITk pixel detector to accommodate the increase in luminosity. The RD53 collaboration was formed to develop the ASIC read out chips that are used inside the ITk pixel detector. In the preproduction RD53B chip, an encoding system was implemented to help shrink data streams and reduce the overall bandwidth of the system. An exploratory effort was undertaken to create a hardware decoder for Field Programmable Gate Arrays (FPGA) to cut down on CPU usage from software decoders later in the system. A parallelized hardware decoder was designed to meet the data rates produced by an RD53B chip. Overall, the final product is a base hardware decoder design that can handle the throughput constraints of a single RD53B and is resource efficient. In this talk I will report necessary background, hardware decoder design, and conclusions based on this design.

Metaplectic Flavor Symmetries from Magnetized Torus

Author: Victor Knapp-Perez¹

¹ UNAM

Corresponding Author: victorknapp@ciencias.unam.mx

Despite of the successful predictions of the Standard model, some of the parameters from the flavor sector, e.g. the mixing angles and the CP phases, do not have an origin within the model. It has been proposed to use modular flavor symmetries to solve this issue, either by imposing them or deriving them from an underlying theory. In this work, we derive the modular symmetries by using the Yukawa couplings given by a magnetized compactified torus. We show that modular transformations of torus give rise to finite metaplectic groups, whose order is determined by the least common multiple of the number of flavors involved. We also comment on the role of supersymmetry in these constructions and outline a path towards non-supersymmetric models with modular flavor symmetries.

Implementation of Jupyter Notebooks into The Reproducible Open Benchmarks for Data Analysis Platform (ROB)

Authors: Aaron Wang^{None}; Ajay Rawat¹; Heiko Mueller^{None}; Shih-Chieh Hsu²

¹ University of Washington

² University of Washington Seattle (US)

Corresponding Authors: hm74@nyu.edu, anrunw@uw.edu

The Reproducible Open Benchmarks for Data Analysis Platform (ROB) is a platform that allows for the evaluation of different data analysis algorithms in a controlled competition-style format [1]. One example for such a comparison and evaluation of different algorithms is the “The Machine Learning Landscape of Top Taggers” paper, which compiled and compared multiple different top tagger neural networks [2]. Motivated by the significant amount of time required to organize and evaluate such benchmarks, ROB provides a platform that automates the collection, execution, and comparison of participant submissions in a benchmark. Although convenient, the ROB currently requires participants to package their submissions into docker containers, which can pose an additional burden due to the steep learning curve.

To increase ease of use, we implement support for the commonly used Jupyter Notebooks [3] in ROB. Jupyter Notebooks are a popular tool that many physicists are already familiar with. Using Jupyter notebooks, physicists are able to combine live code, comments, and documentation inside one document. By utilizing the PaperMill package [4], we allow ROB users to submit their implementations directly as Jupyter Notebooks in order to evaluate different data analysis algorithms without the need to package the code into Docker containers. To demonstrate functionality and spur usage of the ROB, we provide demos using bottom and top tagging neural networks that display the application of the ROB within particle physics as a way of providing a competition style platform for algorithm evaluation [5].

Searching for ultralight bosons using black hole spins measured from gravitational waves

Authors: Ken Ng¹; Salvatore Vitale¹; Otto Hannuksela²; Tjonnie Li³

¹ MIT

² Utrecht University

³ The Chinese University of Hong Kong, Katholieke Universiteit Leuven

Corresponding Author: kenkyng@mit.edu

Clouds of ultralight bosons - such as axions - can form around a rapidly spinning black hole, if the black hole radius is comparable to the bosons' wavelength. The cloud rapidly extracts angular momentum from the black hole, and reduces it to a characteristic value that depends on the boson's mass as well as on the black hole mass and spin. Therefore, a measurement of a black hole mass and spin can be used to reveal or exclude the existence of such bosons. Using hierarchical Bayesian inference, we can simultaneously measure the black hole spin distribution at formation and the mass of the scalar boson. Based on the black holes released by LIGO and Virgo in their GWTC-2, the data strongly disfavors the existence of scalar bosons in the mass range between 1.3×10^{-13} eV and 2.7×10^{-13} eV. Our mass constraint is valid for bosons with negligible self-interaction, that is with a decay constant 10^{14} GeV. The statistical evidence is mostly driven by the two {binary black holes} systems GW190412 and GW190517, which host rapidly spinning black holes. The region where bosons are excluded narrows down if these two systems merged shortly ($\sim 10^5$ years) after the black holes formed. If time permits, we will also discuss the prospect of this search in the coming decade, as well as a multiband technique for precise measurement of boson mass.

Parity, not Peccei-Quinn, to Solve Strong CP

Authors: Amara McCune¹; Giacomo Koszegi²; Isabel Garcia Garcia³; Nathaniel Craig⁴

¹ University of California, Santa Barbara

² UCSB

³ Conseil Europeen Recherche Nucl. (CERN)

⁴ UC Santa Barbara

Corresponding Author: amara@ucsb.edu

Parity solutions to the strong CP problem are a compelling alternative to approaches based on Peccei-Quinn symmetry, particularly given the expected violation of global symmetries in a theory of quantum gravity. The most natural of these solutions break parity at a low scale, giving rise to a host of experimentally accessible signals. In this talk, we give an overview of this class of solutions and assess the simplest parity-based solution in light of LHC and flavor constraints. We further highlight prospects for near-future tests at colliders, tabletop experiments, and gravitational wave observatories. The origin of parity breaking and associated gravitational effects provide new avenues for discovery through EDMs and gravity waves, establishing generalized parity as a promising and testable solution to the strong CP problem.

Multi-TeV Signals of Baryogenesis in Higgs Troika Model

Authors: Matthew Sullivan¹; Hooman Davoudiasl²; Ian Lewis³

¹ *Brookhaven National Laboratory*

² *BNL*

³ *The University of Kansas*

Corresponding Author: msullivan1@bnl.gov

A modest extension of the Standard Model by two additional Higgs doublets - the Higgs Troika Model - can provide a well-motivated scenario for successful baryogenesis if neutrinos are Dirac fermions. Adapting the "Spontaneous Flavor Violation" framework, we consider a version of the

Troika model where light quarks have significant couplings to the new multi-TeV Higgs states. Resonant production of new scalars leading to di-jet or top-pair signals are typical predictions of this setup. The initial and final state quarks relevant to the collider phenomenology also play a key role in baryogenesis, potentially providing direct access to the relevant early Universe physics in high energy experiments. Viable baryogenesis generally prefers some hierarchy of masses between the observed and the postulated Higgs states. We show that there is a complementarity between direct searches at a future 100 TeV pp collider and indirect searches at flavor experiments, with both sensitive to different regions of parameter space relevant for baryogenesis. In particular, measurements of $D - \bar{D}$ mixing at LHCb probe much of the interesting parameter space. Direct and indirect searches can uncover the new Higgs states up to masses of $\mathcal{O}(10)$ TeV, thereby providing an impressive reach to investigate this model.

Status of the Measurement of Neutrino-Electron Elastic Scattering in the NOvA Near Detector

Author: Yiwen Xiao¹

¹ *University of California Irvine*

Corresponding Author: yiwenx7@uci.edu

NOvA is a long-baseline neutrino experiment optimized to observe the oscillation of muon neutrinos to electron neutrinos. It uses a high purity muon neutrino beam produced at Fermilab with central

energy of approximately 1.8 GeV. NOvA consists of a near detector located 1 km downstream of the neutrino production target at Fermilab and a far detector located 810 km away in Ash River, Minnesota. Neutrino cross-section measurements performed at the near detector are affected by a large uncertainty on the absolute neutrino flux. Since the neutrino-electron elastic-scattering cross section can be accurately calculated, the measured rate of these interactions can be used to constrain the neutrino flux. We present the status of the neutrino-electron elastic-scattering measurement using a Convolutional Neural Network (CNN) to identify signal events with high purity.

Linearized Optimal Transport for Jet Physics

Authors: Tianji Cai¹; Junyi Cheng¹; Nathaniel Craig¹; Katy Craig¹; Bernhard Schmitzer²; Matthew Thorpe³

¹ *University of California, Santa Barbara*

² *UNIVERSITÄT GÖTTINGEN*

³ *UNIVERSITY OF MANCHESTER*

Corresponding Author: tianji_cai@ucsb.edu

As an unsupervised machine learning strategy, optimal transport (OT) has been applied to jet physics for the computation of distance between collider events. Here we generalize the Energy Mover's Distance to include both the balanced Wasserstein-2 (W2) distance and the unbalanced Hellinger-Kantorovich (HK) distance. Whereas the W2 distance only allows for mass to be transported, the HK distance allows mass to be transported, created and destroyed, therefore naturally incorporating the total pt difference of the jets. Both distances enjoy a weak Riemannian structure and thus admit linear approximation. Such a linear framework significantly reduces the computational cost and in addition provides a Euclidean embedding amenable to simple machine learning algorithms and

visualization techniques downstream. Here we demonstrate the benefit of this linear approach for jet classification and study its behavior in the presence of pileup.

Measurement of proton and deuteron electric dipole moments using the prototype electric dipole moment ring (PTR)

Author: Richard Talman¹

¹ *Laboratory for Elementary-Particle Physics, Cornell*

Corresponding Author: richard.talman@cornell.edu

Any measurably large elementary particle electric dipole moment (EDM) would constitute physics beyond the standard model. Based on frozen spin polarized beam control technology developed at the COSY laboratory in Juelich, Germany, a conceptual design is presented for a storage ring (PTR) capable of measuring proton (p) and deuteron (d) EDMs. Superimposed electric and magnetic bending make it possible to freeze the spins of simultaneously counter circulating polarized beams. This permits the monotonic accumulation of "out-of-plane" (meaning "out of the horizontal ring plane") precession of the polarization direction of one of the two beams, as caused by the bend fields acting on its particle EDMs, thereby supporting the EDM determination. Bunch accumulation and polarization preparation would be accomplished using an "arcs-only bunch accumulator" reconfiguration of COSY, now side-by-side with PTR in the existing COSY beam hall. Using doubly frozen (p,p), (p,d), and (d,d) proton and deuteron pairings, the EDMs and their differences can be obtained with unprecedented precision. The required spin control technology has already been demonstrated using deuterons in COSY. Existing polarized beam sources, injection, extraction, electron cooling and other existing beam-handling apparatus would be re-deployed. Newly to be constructed would be the PTR ring described in a recent CPEDM report, "Storage ring to search for EDMs of charged particles".

Improved Treatment of Dark Matter Capture in Neutron Stars: Leptonic and Baryonic Targets

Authors: Anthony Thomas¹; Michael Virgato²; Giorgio Busoni³; Nicole Bell⁴; Sandra Robles²

¹ *University of Adelaide*

² *The University of Melbourne*

³ *Max-Planck-Institut für Kernphysik*

⁴ *University of Melbourne*

Corresponding Author: m.virgato@student.unimelb.edu.au

The capture of Dark Matter in Neutron Stars has garnered considerable interest in recent years. This interest is driven by the prospect that the energy deposited by dark matter scattering can heat these objects to infra-red temperatures, which may soon be within reach of observations. In order to obtain reliable results from these searches, proper incorporation of the physics of Neutron stars into the capture process is necessary. Key among these are gravitational focusing, relativistic kinematics, Pauli blocking, and multiple scattering. Additionally, we incorporate the internal structure of the Neutron star through the adoption of an equation of state coupled to the Tolman-Oppenheimer-Volkoff equations. In the case of hadronic targets, we must also account for strong interactions of the targets, which induce an effective mass, and that the momentum transfer is sufficiently large that hadrons cannot be treated as pointlike objects. Accounting for these effects allows us to project sensitivities for dark matter-lepton and nucleon cross sections using dimension-6 effective operators. In many cases, limits are potentially stronger than those obtained from direct detection searches.

Multi-component multiscatter capture of Dark Matter

Authors: Caleb Levy¹; Cosmin Ilie²

¹ *Colgate*

² *Colgate University*

Corresponding Author: cmlevy@colgate.edu

In recent years, the usefulness of astrophysical objects as Dark Matter (DM) probes has become more and more evident, especially in view of null results from direct detection and particle production experiments. The potentially observable signatures of DM gravitationally trapped inside a star, or another compact astrophysical object, have been used to forecast stringent constraints on the nucleon-Dark Matter interaction cross section. Currently, the probes of interest are: at high redshifts, Population III stars that form in isolation, or in small numbers, in very dense DM minihalos at $z \sim 15-40$, and, in our own Milky Way, neutron stars, white dwarfs, brown dwarfs, exoplanets, etc. Of those, only neutron stars are single-component objects, and, as such, they are the only objects for which the common assumption made in the literature of single-component capture, i.e. capture of DM by multiple scatterings with one single type of nucleus inside the object, is valid. In this paper, we present an extension of this formalism to multi-component objects and apply it to Pop III stars, thereby investigating the role of He on the capture rates of Pop III stars. As expected, we find that the inclusion of the heavier He nuclei leads to an enhancement of the overall capture rates, further improving the potential of Pop III stars as Dark Matter probes.

Using Underground Nuclear Accelerators in the Quest for Dark Matter

Author: Marianne Moore¹¹ *University of British Columbia***Corresponding Author:** mmoore@phas.ubc.ca

The existence of dark matter is ubiquitous in cosmological data, yet numerous particle detectors have been thoroughly looking for it without any success. For strongly interacting dark matter, the bounds from these experiments are actually irrelevant; as dark matter enters the atmosphere, it scatters and slows down, such that it has a much lower velocity than the detector threshold when it reaches underground laboratories. In this case, however, it would accumulate within the Earth and reach a density much greater than that of the dark matter halo. Here, I will describe a scheme for adapting present-day underground nuclear physics experiments to detect dark matter within this context. In particular, I will show that accumulated dark matter can be up-scattered to resolvable energies using underground nuclear accelerators, such as LUNA in Gran Sasso, and captured in nearby located low-background detectors.

Backgrounds and Shielding for SuperCDMS SNOLAB

Author: Jack Nelson¹¹ *University of Minnesota***Corresponding Author:** nels8013@umn.edu

SuperCDMS deploys cryogenic germanium and silicon detectors which are sensitive in both the athermal phonon and ionization channels to search for dark matter. In order to observe such a small potential signal, all background sources need to be well understood and then mitigated. Low-background shielding was designed such that the environmental background is negligible compared to the irreducible background due to cosmogenic activation in the detectors themselves. The overall background budget of the SuperCDMS experiment will be presented, along with the iterative process of design, assay, and fabrication of the now complete shielding system.

The THDMa and possible $e+e^-$ signatures

Author: Tania Natalie Robens¹

¹ *Rudjer Boskovic Institute (HR)*

Corresponding Author: tania.robens@cern.ch

The THDMa is a new physics model that extends the scalar sector of the Standard Model by an additional doublet as well as a pseudoscalar singlet and allows for mixing between all possible scalar states. In the gauge eigenbasis, the additional pseudoscalar serves as a portal to the dark sector, with a priori any dark matter spin states. The option where dark matter is fermionic is currently one of the standard benchmarks for the experimental collaborations, and several searches at the LHC constrain the corresponding parameter space. However, most current studies constrain regions in parameter space by setting all but 2 of the 12 free parameters to fixed values.

I will discuss a generic scan on this model, allowing all parameters to float. All current theoretical and experimental constraints are applied. I identify regions in the parameter space which are still allowed after these have been applied and which might be interesting for an investigation at a future e^+e^- collider.

The CMS GE1/1 commissioning and alignment status

Authors: Devin Michael Aebi¹; Hyunyong Kim¹; Towsifa Akhter¹

¹ *Texas A & M University (US)*

Corresponding Author: aebid@tamu.edu

The CMS muon system plays an important role in the discovery of new physics like the Higgs boson and new particles. The next phase of the LHC is planned to increase luminosity to improve the discovery power. The high luminosity LHC (HL-LHC) will be a harsh environment of pp collisions and will require high-performance muon trigger and muon track reconstruction, especially in the endcap region. In order to maintain the performance of the CMS muon system, the CMS collaboration has been developing a Gas Electron Multiplier (GEM) detector for the endcap regions of the CMS muon system. The new sub-detector system requires a new procedure of commissioning and alignment to be developed. We report the status of the GE1/1 commissioning and alignment.

Corresponding Author: wooyoung.jang@uta.edu

Rare nuclear isotope accelerator facilities require high-intensity proton beams to produce different types of nuclear isotopes more copiously. Such requirements provide an excellent opportunity to

search for dark-sector particles such as axion-like particles(ALPs). This presentation will introduce an experimental proposal called DAMSA (Dump-produced Aboriginal Matter Searches at Accelerator) at the RAON (Rare isotope Accelerator complex for ONline experiment) facility, which is under construction in Korea. One of the main features of DAMSA is the proximity of the detector to the target, which enables the exploration of the high-mass region of ALP parameter space. The proximity, however, requires a method to effectively control beam-related neutron backgrounds effectively. We performed a Geant4 Monte Carlo simulation for the neutron production at the target, the proton beam dump, and their interactions inside the detector system. In this talk, we will discuss the current status of the study and its results.

Detector performance and Data Quality monitoring at the NOvA Experiment

Author: Gandrajula Reddy Pratap¹

¹ *NOvA Collaboration*

Corresponding Author: reddypg@virginia.edu

NOvA is a long-baseline neutrino oscillations experiment designed to precisely measure the neutrino oscillation parameters. We do this by directing a beam of predominantly muon neutrinos from Fermilab towards northern Minnesota to measure the rate of electron-neutrino appearance. The experiment consists of two functionally equivalent detectors each located 14.6 mrad off the central axis of Fermilab's nearly 700 kW NuMI neutrino beam, the world's most intense neutrino beam. Both the Near Detector, located 1 km downstream from the beam source, and the Far Detector, located 810 km away in Ash River, MN, were constructed from plastic extrusions filled with liquid scintillator. With the data measured at the Near Detector being used to accurately determine the expected rate at the Far Detector, it is very important to have automated and accurate monitoring of the data recorded by the detectors so any hardware, data acquisition systems or beam issues arising in the 344k (20k) channels of the Far (Near) detector which could affect quality of the datasets collected for physics analyses are determined. I will present the techniques and detector monitoring systems in various stages of data taking and show the NOvA detectors data taking performance up to the end of recent beam run period.

Effects of Primordial Black Holes on Dark Matter Models

Authors: Barmak Shams Es Haghi¹; Paolo Gondolo¹; Pearl Sandick¹

¹ *University of Utah*

Corresponding Author: shams@physics.utah.edu

We investigate the effects of producing dark matter by Hawking evaporation of primordial black holes (PBHs) in scenarios that may have a second well-motivated dark matter production mechanism, such as freeze-out, freeze-in, or gravitational production. We show that the interplay between PBHs and the alternative sources of dark matter can give rise to model-independent modifications to the required dark matter abundance from each production mechanism, which in turn affect the prospects for dark matter detection. In particular, we demonstrate that for the freeze-out mechanism, accounting for evaporation of PBHs after freeze-out demands a larger annihilation cross section of dark matter particles than its canonical value for a thermal dark matter. For mechanisms lacking thermalization due to a feeble coupling to the thermal bath, we show that the PBH contribution to the dark matter abundance leads to the requirement of an even feebler coupling. Moreover, we show that when a large initial abundance of PBHs causes an early matter-dominated epoch, PBH evaporation alone cannot explain the whole abundance of dark matter today. In this case, an additional production mechanism is required, in contrast to the case when PBHs are formed and evaporate during a radiation-dominated epoch.

Asymmetric Reheating by Primordial Black Holes

Authors: Barmak Shams Es Haghi¹; Pearl Sandick¹; Kuver Sinha²

¹ *University of Utah*

² *University of Oklahoma*

Corresponding Author: shams@physics.utah.edu

We investigate Hawking evaporation of a population of primordial black holes (PBHs) as a novel mechanism to populate a dark sector which consists of self-interacting scalar dark matter with pure gravitational coupling to the visible sector. We demonstrate that depending on initial abundance of PBHs and the dark matter mass, the dark sector can reach chemical equilibrium with a temperature above, below, or equal to the temperature of the visible sector at the same time. Due to the absence of non-gravitational mediators between two sectors, any temperature asymmetry between two sectors will persist and evolve to keep the entropy of each sector conserved during the expansion of the Universe. We show that an equilibrated dark sector populated by Hawking evaporation of PBHs can explain the dark matter relic abundance today for dark matter in the MeV-TeV mass range.

Probing MeV-Range Scalar Bosons and TeV Range Vectorlike Fermions Associated with $U(1)_{T3R}$ at the LHC

Authors: Alfredo Gurrola¹; Dale Adam Julson¹; Bhaskar Dutta²; Jason Kumar^{None}; Teruki Kamon³

¹ *Vanderbilt University (US)*

² *Texas A&M University*

³ *Texas A & M University (US)*

Corresponding Author: daleadamjulson@gmail.com

Recently, there has been great interest in beyond-the-Standard Model (BSM) physics involving new low-mass matter and mediator particles. One such model, $U(1)_{T3R}$, proposes a new U(1) gauge symmetry under which only right-handed fermions of the standard model are charged, as well as the addition of new vector-like fermions (e.g., χ_t) and a new dark scalar particle (ϕ) whose vacuum expectation value breaks the $U(1)_{T3R}$ symmetry. For this work, we perform a feasibility study to explore the mass ranges for which these new particles can be probed at the LHC. We consider the interaction $pp \rightarrow \chi_t t \phi$ in which the top quark decays purely hadronically, the χ_t decays semi-leptonically ($\chi_t \rightarrow W + b$), and the ϕ decays to two photons. The proposed search is expected to achieve a discovery reach with signal significance greater than 5σ for χ_t masses up to 1.8 TeV and ϕ masses as low as 1 MeV, assuming an integrated luminosity of 3000 fb^{-1} .

Reconstructing proton-proton collision positions at the Large Hadron Collider with a D-Wave quantum computer

Author: Andrew Wildridge¹

Co-authors: Souvik Das¹; Sachin Vaidya²; Andreas Jung¹

¹ *Purdue University (US)*

² *Purdue University*

Corresponding Author: andrew.james.wildridge@cern.ch

Clustering of charged particle tracks along the beam axis is the first step in reconstructing the positions of proton-proton (p-p) collisions at Large Hadron Collider (LHC) experiments. In this talk, we formulate this problem for a 2048 qubit D-Wave quantum computer that works by quantum annealing. We showcase the performance of the quantum annealer on artificial events generated from p-p collision and track distributions measured by the Compact Muon Solenoid experiment at the LHC. This performance is enhanced via multiple hardware optimizations which are outlined in the talk. The quantum clustering algorithm is found to be limited by the connectivity of the qubits and the overall efficiency of the algorithm in addressing event topologies with more than 5 collisions. Current research directions are highlighted in extending this algorithm to be compatible with operating at the full LHC-scale problem complexities relevant for particle physics research.

Muonium-antimuonium oscillations in effective field theory

Authors: Alexey Petrov¹; Renae Conlin¹

¹ *Wayne State University*

Corresponding Author: au9969@wayne.edu

We revisit a discussion of one possible way to search for lepton flavor violation (LFV), muonium-antimuonium oscillations. This process violates muon lepton number by two units and could be sensitive to the types of beyond the standard model physics that are not probed by other types of LFV processes. Using techniques of effective field theory, we calculate the mass and width differences of the mass eigenstates of muonium. We argue that its invisible decays give the parametrically leading contribution to the lifetime difference and put constraints on the scales of new physics probed by effective operators in muonium oscillations.

Corresponding Author: gtx@physik.uni-siegen.de

In this talk we will discuss the production of three Higgs bosons in the LHC and at a proton-proton collider running at a centre-of-mass energy of 100 TeV. We will argue that the seemingly challenging

6-bottom jets final state is a very good candidate to investigate triple Higgs production within and beyond the SM in proton-proton colliders. In particular we will consider three different scenarios: one in which the triple and quartic Higgs boson self-couplings are not affected by new physics phenomena besides the Standard Model (SM) and in addition, we will explore two possible SM extensions by one and two new scalars. We will show that a 100 TeV machine can impose competitive constraints on the quartic coupling in the SM-like scenario. In the case of the scalar extensions of the SM, we will show that large significances can be obtained in the LHC and the 100 TeV collider while obeying current theoretical and experimental constraints including a first order electroweak phase transition.

Total Neutron Cross Section Measurement with a 3D Projection Scintillator Tracker for Long-baseline Neutrino Experiments

Author: POOI SEONG CHONG¹

Co-author: YANG GUANG²

¹ *University of Pennsylvania*

² *Stony Brook University*

Corresponding Author: eric0722@upenn.edu

The long-baseline neutrino oscillation experiments depend on detailed models of neutrino interactions on nuclei. However, these models constitute an important source of systematic uncertainty partly due to the missing information of the final state neutrons in the detectors to date. As such, neutron information is desired in the near detectors of upcoming long-baseline neutrino experiments. Here, we are proposing a three-dimensional projection scintillator tracker to be used as a near detector component in the next generation long-baseline neutrino experiments such as T2K upgrade and DUNE. Due to the good timing resolution and fine granularity, this technology is capable of measuring neutron kinetic energy from neutrino interactions and can provide valuable data for refining neutrino interaction models and better reconstruct the neutrino energy. Neutron beam data has been taken in Los Alamos National Lab (LANL) in both 2019 and 2020 with neutron energy ranging from 0 to 800 MeV using two of such prototype detectors. In order to demonstrate the capability of the neutron detection, a total neutron-scintillator cross section is measured with one of the prototypes and compared to external measurements. In this presentation, the details of the cross section measurement and the systematic uncertainty handling will be presented.

Neural Network-based Resolutions for Pion Energy Calibration with the ATLAS Detector

Author: Adithya Suresh¹

Co-authors: Alexander Chkodrov²; Shih-Chieh Hsu³; Saransh Kacharia¹; Elham E Khoda²

¹ *University of Washington*

² *University of Washington (US)*

³ *University of Washington Seattle (US)*

Corresponding Author: adithyas@cs.washington.edu

Calibrating the pion energy response is a core component of reconstruction in the ATLAS calorimeter. Deep learning techniques have shown the best energy resolution for a wide range of particle momenta [1]; to further improve the pion energy resolution, a Mixture Density Network (MDN) based deep learning algorithm is explored. In addition to estimating the energy, the MDN also estimates the associated energy resolution for each individual pion; this enables the resolution to be quantified on a per pion basis for the first time. This work demonstrates the potential of MDN-based low-level hadronic calibrations to significantly improve the quality of particle reconstruction in the ATLAS calorimeter. This work is done in the context of the ML4Pions group in the ATLAS Collaboration.

Quantum Formation of Topological Defects

Authors: George Zahariade¹; Mainak Mukhopadhyay²; Tanmay Vachaspati²

¹ *Institut de Física d'Altes Energies (IFAE), Universitat Autònoma de Barcelona*

² *Arizona State University*

Corresponding Author: mmukhop2@asu.edu

Quantum field theories generally contain small quantum excitations around a true vacuum that we call particles and large classical structures called solitons that interpolate between different degenerate vacua. Often the solitons have a topological character and are then also known as topological defects of which kinks, domain walls, strings, and magnetic monopoles are all examples. After a quantum phase transition, the quantum vacuum can break up to form these classical topological defects. We study these phase transitions with global symmetry breakings and their dynamics, where the only interactions are with external parameters that induce the phase transition. We evaluate the number densities of the defects in 1,2 and 3-dimensions (kinks, vortices, and monopoles respectively) and find that they scale as $t^{-d/2}$ and evolve towards attractor solutions that are independent of the *externally* controlled time dependence.

Search for Accelerator-produced Dark Matter with the Coherent CAPTAIN Mills detector

Author: Edward Dunton¹

¹ *Columbia University*

Corresponding Author: e.dunton@columbia.edu

Cosmological observations indicate that our universe contains dark matter (DM), yet we have no measurements of its microscopic properties. Whereas the gravitational interaction of DM is well understood, its interaction with the Standard Model is not. Direct detection experiments, the current standard, search for nuclear recoil interactions and have low-mass sensitivities down to ~ 1 GeV. A path to detect DM with masses below 1 GeV is the use of accelerators producing boosted low-mass DM. The Coherent CAPTAIN Mills (CCM) experiment uses a 10-ton liquid argon scintillation detector at the Lujan Center at LANSCE to search for physics beyond the standard model. The Lujan Center delivers a 100-kW, 800 MeV, 290 ns wide proton pulse onto a tungsten target at 20 Hz to generate a stopped pion source. The fast pulse, in combination with the speed of the CCM scintillation detector, is crucial for isolating prompt speed of light particles generated by the stopped pion source and reducing neutron and steady state background. In this talk I will discuss CCM's search for Vector Portal Dark Matter by showing the results from our Fall 2019 run, as well as the projected reach of the experiment based on the current upgrades to the CCM detector.

All-Hadronic search for Vector-Like Quarks using the BESTagger with 137 fb^{-1} of $\sqrt{s} = 13$ TeV proton-proton collisions collected by CMS

Author: Johan Sebastian Bonilla¹

¹ *University of California Davis (US)*

Corresponding Author: johan.sebastian.bonilla@cern.ch

We present the status of our all-hadronic analysis in search of pair-produced Vector-Like Quarks (VLQs) using the Boosted Event Shape Tagger (BEST) with the CMS detector using 137 fb^{-1} of $\sqrt{s} = 13$ TeV proton-proton collisions at the LHC. VLQs are motivated by models which predict compositeness of the scalar Higgs boson, and which avoid increasing constraints from Higgs measurements. In the all-hadronic channel, this analysis is sensitive to all possible VLQ decay modes: $T(B) \rightarrow t(b)H/t(b)Z/b(t)W$, capturing the highest branching fraction of each process. The high mass of the VLQs produce highly boosted objects in the final state which can be reconstructed as anti- k $R=0.8$ jets and identified as either $QCD/b/W/Z/H/t$ using the BESTagger. The tagger boosts jet constituents into various rest frames and uses neural networks to find correlations between event shape variables, such as Fox-Wolfram moments and sphericity, to determine the category of identification. We define signal regions by the classification of the highest four jets in p_T . We estimate our QCD-dominant background with a data-driven 3-jet control region, then fit its normalization simultaneously with simulations of well-modeled sub-dominant background such as $t\bar{t}$ and W/Z +jets. The HT (scalar sum p_T) of the event is scanned for an excess of signal in 120 of 126 possible combinations, and the least 6 signal-rich combinations are used as validation regions for the QCD estimation. The analysis is in progress and plans to be completed soon.

Dark Matter and Reactor CEvNS Physics Reach with SBC Liquid Argon Bubble Chambers

Authors: Russell Neilson¹; Russell Neilson^{None}

¹ *Drexel University*

Corresponding Authors: russellneilson79@gmail.com, neilson@drexel.edu

The Scintillating Bubble Chamber (SBC) Collaboration is constructing a 10-kg liquid argon bubble chamber with scintillation readout. The goal for this new technology is to achieve a nuclear recoil detection threshold as low as 100 eV with near complete discrimination against electron recoil events. Following initial characterization in a near-surface site at Fermilab, an underground deployment is planned at SNOLAB for a dark matter search. The sub-keV nuclear recoil threshold would enable sensitivity to GeV-mass WIMPs, and a future ton-scale version could probe for dark matter down to the solar neutrino floor. The same technology has been considered for a first measurement of coherent elastic neutrino nucleus scattering (CEvNS) with reactor neutrinos. With high statistics and high signal-to-background, precision searches for beyond-standard-model physics would be possible. I will discuss the physics case for the liquid argon bubble chamber technology, and SBC studies of backgrounds and nuclear recoil calibration approaches.

Overview of the GRAMS (Gamma-Ray and AntiMatter Survey) Project

Author: Tsuguo Aramaki¹

¹ *Northeastern University*

Corresponding Author: t.aramaki@northeastern.edu

GRAMS (Gamma-Ray and AntiMatter Survey) is a next-generation proposed balloon/satellite mission that will be the first to target both MeV gamma-ray observations and antimatter-based indirect dark matter searches with a LArTPC (Liquid Argon Time Projection Chamber) detector. Astrophysical observations at MeV energies have been poorly explored and long-neglected. With a cost-effective, large-scale LArTPC, a single LDB (Long-Duration Balloon) flight could provide an order of magnitude improved sensitivity compared to previous experiments. We can uniquely measure gamma rays from annihilating dark matter and evaporating primordial black holes. Additionally, GRAMS can extensively explore dark matter parameter space via antimatter measurements. In particular, low-energy antideuterons can be background-free dark matter signatures. In this talk, I will give an overview and the current status of the GRAMS project.

Measurement of the complete top-quark polarization vector in t -channel single-top-quark production with ATLAS detector

Author: Chi Wing Ng¹

Co-authors: Joseph Boudreau²; Huacheng Cai¹; James Alfred Mueller¹

¹ *University of Pittsburgh (US)*

² *University of Pittsburgh*

Corresponding Author: chi.wing.ng@cern.ch

A simultaneous measurement of the three components of the top-quark and top-antiquark polarization vectors in t -channel single-top-quark production is presented. Due to the large mass of the top quark, the $t \rightarrow Wb$ decay occurs before hadronization, giving one access to its polarization through the angular distribution of the decay products. The analysis we present uses an integrated luminosity of 139 fb^{-1} of proton-proton collisions at 13 TeV, collected with the ATLAS detector at the LHC. We also discuss the more intricate analysis of the quadruple-differential decay rate of t -channel single-top-quark, which is currently in progress; its purpose is the simultaneous determination of four decay amplitudes and their phases in addition to all three components of the polarization vector for top quarks and antiquarks separately. Prospects for constraining anomalous couplings/Effective-Field-Theory coefficients with this analysis are also discussed.

The possibility that tiny violations of Lorentz invariance may occur in nature and be detectable with existing technology has been intensely pursued for over two decades. Despite there being no indication for Lorentz violation, many potential signatures, particularly in the QCD and electroweak sectors, remain critically unexamined. Recent theoretical work on Lorentz violation grounded in effective theory has produced an abundance of novel collider observables amenable to sidereal-time analyses. In this talk, I discuss the prospects for studying quark-sector operators contributing to deep inelastic scattering and the Drell-Yan process at existing and future colliders.

Self-interacting neutrinos as a solution(?) to the Hubble tension

Authors: Anirban Das¹; Subhajit Ghosh²

¹ *SLAC National Accelerator Laboratory*

² *Notre Dame University*

Corresponding Author: anirband@slac.stanford.edu

Self-interaction among the neutrinos in the early Universe has been proposed as a solution to the Hubble tension, a discrepancy between the measured values of the Hubble constant from CMB and low-redshift data. However, flavor-universal neutrino self-interaction is highly constrained by BBN and several laboratory experiments such as, tau and K-meson decay, double-neutrino beta decay etc. In this talk, I will discuss about the cosmology if only one or two neutrino states are self-interacting. Such flavor-specific interactions are less constrained by the laboratory experiments. Finally, I will talk about the feasibility of addressing the Hubble tension in the framework of such flavor-specific neutrino self-interaction.

We consider an explicit effective field theory example based on the Bousso-Polchinski framework with a large number N of hidden sectors contributing to supersymmetry breaking. Each contribution comes from four form quantized fluxes, multiplied by random couplings. The soft terms in the observable sector in this case become random variables, with mean values and standard deviations which are computable. We show that this setup naturally leads to a solution of the flavor problem in low-energy supersymmetry if N is sufficiently large. We investigate the consequences for flavor violating processes at low-energy and for dark matter.

Dark, chiral fermions carrying lepton flavor quantum numbers are natural candidates for freeze-in. Small couplings with the Standard Model fermions of the order of lepton Yukawas are 'automatic' in the limit of Minimal Flavor Violation. In the absence of total lepton number violating interactions, particles with certain representations under the flavor group remain absolutely stable. For masses in the GeV-TeV range, the simplest model with three flavors, leads to signals at future direct detection experiments like DARWIN. Interestingly, freeze-in with a smaller flavor group such as $SU(2)$ is already being probed by XENON1T.

We show that assuming flavour violation in the first two generations of sfermions in the decoupling limit leads to interesting consequences for proton decay. Assuming

the decoupling sfermions lie within 30 TeV, for the decay mode $p \rightarrow e^+\pi^0$, which has sensitivity beyond that of DUNE and Hyper K is brought within the reach of those experiments. The most of the decay modes which is $p \rightarrow K^+\bar{\nu}_e$ which essentially rules this model out for this range of masses, is now able to survive and further interestingly can be explored at DUNE and HyperK. Finally partial decoupling has interesting consequences for the mode $p \rightarrow K^+\bar{\nu}_\tau$.

In the Standard Model, we cannot obtain the mechanism how to derive the left-handed neutrino masses. Our strategy to solve it is to exploit the Seesaw Mechanism. To get the right-handed Majorana neutrino masses for the Seesaw Mechanism, we utilized and studied the D-brane instanton effect with magnetized orbifold models on torus. Many models can be constructed by changing the magnetic fluxes. We listed up all models consistent with the Standard Model and pointed out that our calculations are consistent with the Modular transformation on the torus.

Leptogenesis from $SU(5)$ GUT with \mathcal{T}_{13} Family Symmetry

Author: Moinul Rahat¹

¹ *University of Florida*

Corresponding Author: mrahat@ufl.edu

In a seesaw scenario, GUT and family symmetry can severely constrain the structure of the Dirac and Majorana mass matrices of neutrinos. We will discuss an interesting case where these matrices are related in such a way that definite predictions for light neutrino masses are achieved without specifying the seesaw scale. This opens up the possibility to consider both high- and low-scale leptogenesis. We will explore both of these possibilities in an $SU(5) \times \mathcal{T}_{13}$ model and show that sub-GeV right-handed neutrinos with active-sterile mixing large enough to be probed by DUNE can explain baryon asymmetry of the Universe through resonant leptogenesis.

Beyond Standard Model / 303**Updated status of the gluino searches in pMSSM in the light of latest LHC data and Dark Matter constraints****Authors:** Abhi Mukherjee¹; Nabanita Ganguly^{None}; Saurabh Niyogi²; Sujoy Poddar³¹ *University of Kalyani*² *Gokhale Memorial Girls' College*³ *Diamond Harbour Women's University***Corresponding Author:** abhiphys18@klyuniv.ac.in

Minimal Supersymmetric Standard Model (MSSM) is one of the most well-motivated and well-studied scenarios for going beyond the Standard Model (SM). Apart from solving the hierarchy problem, one of the primary motivations is the presence of a suitable dark matter (DM) candidate, namely the lightest neutralino, in the particle spectrum of SUSY. Measurement of DM relic density of the universe by the WMAP/PLANCK experiments puts the model under probe. In addition, stringent constraints on the masses of strongly interacting sparticles have also been shown at the Large Hadron Collider (LHC) experiment by analysing **Run II** data for specific simplified models. However, many assumptions made by the experimental collaborations can not be realized in the actual theoretically motivated models. In this study, we revisit the bound on the gluino mass placed by the ATLAS collaboration. We reveal that the exclusion region is shrunk in the $M_{\tilde{g}} - M_{\tilde{\chi}_1^0}$ plane in the pMSSM scenario corresponding to different hierarchies of left and right squark mass parameters. Importantly, for higgsino type lighter electro-weakinos, the bound on gluino mass from 1l + jets + MET search practically does not exist. We have also performed detailed analysis on neutralino dark matter and have found that in most of the region of LSP mass range, required relic density is achieved and also, the direct as well as the indirect detection constraints are satisfied.

Dark Matter / 304**g-2 Dark Sector Portal: U(1)_{Lμ-Lτ} Solution to Dark Matter****Authors:** Douglas Tuckler^{None}; Timothy Hapitas¹; Yue Zhang¹¹ *Carleton University***Corresponding Author:** timhapitas@gmail.com

The existence of dark matter is widely accepted, with a well motivated theoretical candidate being a class of particles known as WIMPs (weakly interacting massive particles), which appear in the spectra of many extensions to the standard model.

We explore a particular WIMP-like model in which fermionic dark matter weakly couples to the muon/tau sectors of the standard model through a new vector boson Z' , in addition to electrically charged particles through kinetic mixing of the Z' with the SM photon. As well as the model potentially providing a candidate dark matter particle, the hypothetical Z' could also aid in explaining the discrepancy between the predicted and observed value of the anomalous magnetic dipole moment of the muon.

Cosmological observations of the dark matter relic density along with findings from direct detection attempts allow us to tightly constrain the parameter space of the model. By initially assuming a momentum independent kinetic mixing parameter, it is difficult for the resulting parameter space to satisfy the restrictions imposed by both sets of experimental results. In this talk, we focus on the work done to remedy this disagreement. Our work involves an attempt at softening the direct detection constraint by considering the general case in which the mixing parameter is momentum dependent. We construct it in such a way that it vanishes in the zero-momentum transfer limit, which results in a viable parameter space. Our goal is then to compare model derived quantities including interaction cross sections and early universe annihilation rates to well established experimental bounds to determine if the resulting parameter space is consistent with the constraints imposed by both direct detection and relic abundance.

A Novel Scintillator Detector for the Mu2e-II Experiment and a Muon Tomography Probe of the Interior of the Great Pyramid

Author: Edmond Dukes^{None}

Corresponding Author: ecd3m@virginia.edu

The Mu2e experiment is designed to search for the charged-lepton-flavor-violating process, μ^- to a e^- , with unprecedented sensitivity. The single 105-MeV electron that results from this process can be mimicked by electrons produced by cosmic-ray muons traversing the detector. An active veto detector surrounding the apparatus is used to detect incoming cosmic-ray muons. To reduce the backgrounds to the required level it must have an efficiency of about 99.99% as well as excellent hermeticity. The detector consists of four layers of scintillator counters, each with two embedded wavelength-shifting fibers, whose light is detected by silicon photomultipliers. An upgrade of the experiment, Mu2e-II, that will provide an order of magnitude more sensitivity is under design. The

cosmic-ray veto detector is being redesigned to handle the higher rates. This redesign is also being used for a proposed high-resolution probe of the interior of the Great Pyramid of Khufu. The design and expected performance of the detector will be described.

Direction Reconstruction using a CNN for GeV-Scale Neutrinos in IceCube

Author: Shiqi Yu¹

¹ *ANL/IIT*

Corresponding Author: syu21@hawk.iit.edu

The IceCube Neutrino Observatory is designed to observe neutrinos interacting deep within the South Pole ice. It consists of 5,160 digital optical modules, which are arrayed over a cubic kilometer from 1,450 m to 2,450 m depth. At the lower center of the array is the DeepCore subdetector, which has a denser configuration that lowers the observable energy threshold to about 5 GeV and creates the opportunity to study neutrino oscillations with low energy atmospheric neutrinos. A precise reconstruction of neutrino direction is critical in the measurements of oscillation parameters. In this presentation, I will discuss the direction reconstruction of GeV-scale neutrinos in IceCube by using a convolutional neural network (CNN) and compare the result to that of the current likelihood-based reconstruction algorithm.

System for on-Axis Neutrino Detection (SAND) as part of the DUNE near detector

Author: Guang Yang¹

¹ *Stony Brook University*

Corresponding Author: guang.yang.1@stonybrook.edu

In order to achieve a precise measurement of the leptonic CP violation phase, Deep Underground Neutrino Experiment (DUNE) will employ four 10 kt scale far detector modules and a near detector complex.

In the near detector complex, a System for on-Axis Neutrino Detection (SAND) is located downstream of a liquid-argon TPC (LAr) and a high pressure gaseous-argon TPC (GAR). SAND consists of an inner tracking system, surrounded by the KLOE superconducting magnet with an electromagnetic calorimeter inside. Due to the high event rate and accurate neutrino energy reconstruction capability, SAND can serve as a good beam monitor. Besides, SAND provides comprehensive measurements on non-Ar targets allowing constraints on the A-dependence of neutrino interaction models. In addition, with the capability of neutron kinetic energy detection, a full reconstruction of

neutrino interaction would be possible, which opens new ways to analyze the events. In this talk, a number of physics studies and the latest design of SAND will be presented.

HeRALD: Dark Matter Direct Detection with Superfluid 4He

Author: Pratyush Patel¹

¹ *University of Massachusetts Amherst*

Corresponding Author: pratyushkuma@umass.edu

ABSTRACT:

HeRALD, the Helium Roton Apparatus for Light Dark Matter, will use a superfluid 4He target to probe the sub-GeV dark matter parameter space. The HeRALD design is sensitive to all signal channels produced by nuclear recoils in superfluid helium: singlet and triplet excimers, as well as phonon-like excitations of the superfluid medium. Excimers are detected via calorimetry with Transition-Edge-Sensor readout in and around the superfluid helium. Phonon-like vibrational excitations eject helium atoms from the superfluid-vacuum interface which are detected by adsorption onto calorimetry suspended above the interface. I will discuss the design, sensitivity projections, and ongoing R&D for the HeRALD experiment. In particular, I will present an initial light yield measurement of superfluid helium down to order 50 keV.

Probing non-standard neutrino interactions with low energy neutrino-electron elastic scattering in reactor experiments

Authors: Adrian Raphael Thompson¹; Ankur Verma¹; Bhaskar Dutta^{None}; Sumit Ghosh¹; Tianjun Li²

¹ *Texas A & M University*

² *Chinese Academy of Sciences*

Corresponding Author: averma1@tamu.edu

Reactor experiments provide an excellent platform to investigate the atomic ionization effects induced by the unexplored neutrino interaction channels. Including the atomic effects in our calculations, we study the neutrino-electron scattering by reactor anti-neutrinos in low-energy electron recoil detectors such as Si/Ge in light of neutrino non-standard interactions with leptons. We find that the crystal structure in Si/Ge yields a sizable suppression to the neutrino-electron scattering cross-section when compared to the free-electron approximation. We present our sensitivity results for the light vector and scalar mediator case. The explanation of the excess in the recent Xenon1T result can also be investigated at the reactor experiments since the reactors have a similar energy flux profile to solar neutrinos with characteristic neutrino energies <1 MeV.

Design and studies for the Mu2e-II tracker

Author: Giovanni Francesco Tassielli¹

Co-author: Daniel Ambrose²

¹ *Università di Bari & INFN Lecce (IT)*

² *University of Minnesota*

Corresponding Author: gianfranco.tassielli@cern.ch

The upgrade of the Mu2e experiment at Fermilab, Mu2e-II, is proposed to improve the expected Mu2e sensitivity. Mu2e-II will search for the neutrinoless conversion of a muon into an electron in the field of an Al nucleus, with a sensitivity up to few 10^{-18} .

As for Mu2e, the tracker system for the Mu2e-II will be responsible for precisely measuring the momentum of the conversion electron to distinguish it from the background electrons coming from the muons decay in orbit.

To meet the requirements, a preliminary calculation indicates that the Mu2e-II tracker system should be even lighter than the Mu2e tracker by reaching a total material budget of about $4 \times 10^{-3} X/X_0$. Moreover, it must preserve or increase the rate capability of the M2e tracker. We present the ongoing R&D studies and some preliminary simulation results for a tracker made with about 20,000 8um thin-walled straw tubes operating in a vacuum of 10^{-4} torr and for possible alternatives.

Directly Probing the Higgs-top Coupling at High Scales

Authors: Roshan Mammen Abraham¹; Dorival Gonçalves¹; Tao Han²; Sze Ching Iris Leung²; Han Qin²

¹ *Oklahoma State University*

² *University of Pittsburgh*

Corresponding Author: rmammen@ostateemail.okstate.edu

The top-quark Yukawa coupling y_t is the strongest interaction of the Higgs boson in the Standard Model (SM) with $y_t \sim 1$. Due to its magnitude, it plays a central role in Higgs phenomenology in the SM and would be most sensitive to physics beyond the Standard Model. The top Yukawa can be directly measured at the LHC via top pair production in association with a Higgs boson $t\bar{t}h$. We study new physics effects for the Higgs-top coupling at high scales, using jet substructure techniques. We present the high-luminosity LHC sensitivity to new physics parametrized in the EFT framework and through a general Higgs-top form factor.

Dark Matter / 313**Continuum-Mediated Self-Interacting Dark Matter****Authors:** Flip Tanedo¹; Ian Chaffey²; sylvain fichet^{None}¹ *UC Riverside*² *University of California, Riverside***Corresponding Author:** ichaf001@ucr.edu

Dark matter self-interactions have been proposed as a solution to various astrophysical small-scale structure anomalies. We explore the scenario in which dark matter self-interacts through a continuum of low-mass states. This happens if dark matter couples to a strongly-coupled nearly-conformal hidden sector. This type of theory is holographically described by brane-localized dark matter interacting with bulk fields in a slice of 5D anti-de Sitter space. The long-range potential in this scenario depends on a non-integer power of the spatial separation. We find that continuum mediators introduce novel power-law scalings for the scattering cross section, opening new possibilities for dark matter self-interaction phenomenology.

This talk presents a model of the electron-like excess observed by the MiniBooNE experiment comprised of oscillations involving a new mass state, ν_4 , at $\mathcal{O}(1)$ eV and a high mass state, \mathcal{N} , at $\mathcal{O}(100)$ MeV that decays to $\nu + \gamma$ via a dipole interaction.

Short baseline oscillation data sets (omitting MiniBooNE appearance data) are used to predict the oscillation parameters. We simulate the production of \mathcal{N} along the Booster Neutrino Beamline via both Primakoff upscattering ($\nu A \rightarrow \mathcal{N}A$) and Dalitz-like neutral pion decays ($\pi^0 \rightarrow \mathcal{N}\nu\gamma$).

The simulated events are fit to the MiniBooNE neutrino energy and visible scattering angle data separately to find a joint allowed region at 95% CL.

An example point in this region with coupling of $3.6 \times 10^{-7} \text{ GeV}^{-1}$, \mathcal{N} mass of 394 MeV, oscillation mixing angle of 6×10^{-4} and mass splitting of 1.3 eV^2 has $\Delta\chi^2/dof$ for the energy and angular fit of 15.23/2 and 37.80/2, respectively.

The Mu2e Experiment: A Search for Charged Lepton Flavor Violation

Author: Kate Ciampa^{None}

Corresponding Author: ciamp009@umn.edu

The goal of the Mu2e experiment is to test the conservation of charged lepton flavor with a search for neutrinoless muon to electron conversion in the Coulomb field of a nucleus. To extend the sensitivity of this measurement by four orders of magnitude beyond present limits, the Mu2e design incorporates several innovations to produce an intense muon beam, detect signal electrons, and reduce sources of background. This talk will give an overview of the theory and physical significance of the conversion measurement, and will discuss the physics concepts implemented in the beam sequence and primary detector components. Particle progression through the Mu2e apparatus begins with a pulsed proton beam that interacts with nuclei to produce pions, which decay to muons as they travel through the production and transport solenoids, guided by strong magnetic fields. When particles from the resulting muon beam are stopped by a target in the detector solenoid and trapped in atomic orbitals, decay via neutrinoless muon-to-electron conversion would violate charged lepton flavor and indicate the involvement of physics beyond the Standard Model. The Mu2e tracker, a low-mass array of straw drift cells, will identify high-energy signal electrons against a background of electrons from muon decay in orbit by precisely measuring their trajectories through a magnetic field, with additional energy and timing measurements made by the electromagnetic calorimeter. Besides decay in orbit electrons, the other dominant source of background comes from cosmic ray particle interactions, identified and vetoed by layers of active shielding covering the detector. Components of the Mu2e experiment are at various stages of construction and testing, and this talk will conclude with an overview of the current status.

Discovering new forces with gravitational waves from supermassive black holes

Authors: Jeff Dror¹; Benjamin Lehmann²; Hiren Patel³; Stefano Profumo³

¹ *Lawrence Berkeley National Laboratory*

² *UC Santa Cruz*

³ *University of California, Santa Cruz*

Corresponding Author: benvlehmann@gmail.com

Supermassive black hole binary mergers generate a stochastic gravitational wave background detectable by pulsar timing arrays. While the amplitude of this background is subject to significant uncertainties, the frequency dependence is a robust prediction of general relativity. We show that the effects of new forces beyond the Standard Model can modify this prediction and introduce unique features into the spectral shape. In particular, we consider the possibility that black holes in binaries are charged under a new long-range force, and we find that pulsar timing arrays are capable of robustly detecting such forces. Supermassive black holes and their environments can acquire charge due to high-energy particle production or dark sector interactions, making the measurement of the spectral shape a powerful test of fundamental physics.

Heavy leptons and the muon anomalous magnetic moment

Authors: Keith Hermanek¹; Navin McGinnis²; Radovan Dermisek¹

¹ *Indiana University*

² *TRIUMF*

Corresponding Author: nmcginnis@triumf.ca

The recently updated measurement of the muon anomalous magnetic moment strengthens the motivations for new particles beyond the Standard Model. We discuss two well-motivated 2HDM scenarios with vectorlike leptons as well as the Standard Model extended with vectorlike lepton doublets and singlets as possible explanations for the anomalous measurement. In these models we find that, with couplings of order 1, new leptons as heavy as 8 TeV can explain the anomaly, well out of reach of expectations for the LHC. We summarize the implications of future precision measurements of Higgs- and Z- boson couplings which can provide indirect probes of these scenarios and their viability to explain the anomalous magnetic moment of the muon.

The next generation of neutrino telescopes, including Baikal-GVD, KM3NeT, P-ONE, TAMBO, and IceCube-Gen2, will be able to determine the flavor of high-energy astrophysical neutrinos with 10% uncertainties. With the aid of future neutrino oscillation experiments — in particular JUNO, DUNE, and Hyper-Kamiokande — the regions of flavor composition at Earth that are allowed by neutrino oscillations will shrink by a factor of ten between 2020 and 2040. We critically examine the ability of future experiments and show how these improvements will help us pin down the source of high-energy astrophysical neutrinos and a sub-dominant neutrino production mechanism with and without unitarity assumed. As an illustration of beyond-the-Standard-Model physics, we also show that the future neutrino measurements will constrain the decay rate of heavy neutrinos to be below $2 \times 10^{-5} m/eV/s$ assuming they decay into invisible particles.

Improvements to Cosmic Muon Identification Using Machine Learning

Authors: Mohit Srivastav¹; Yuri Oksuzian²

¹ *University of Virginia*

² *Argonne National Lab*

Corresponding Author: mvs2dq@virginia.edu

The Mu2e Experiment at Fermilab is looking for neutrino-less conversion of a muon to an electron. The experiment requires an extremely efficient Cosmic Ray Veto (CRV) to detect cosmic muons and ignore them so they cannot be confused with a successful direct conversion. Similarly, noise generated by neutrons and gamma rays from muon beam production/transportation can challenge the operation of the CRV, and creates difficulties in looking at actual events involving muons by creating experimental dead time. To try to help maintain adequate efficiency levels and minimize dead time, machine learning is being used in an attempt to improve the rejection efficiency and noise event classification. The model being used is a neural net, using Monte Carlo dropout for error analysis and better prediction, built by the Keras library in Python, and is trained on a simulated dataset of noise and cosmic muon events generated using Geant4.

Polynomial Noise Subtraction in Lattice QCD

Author: Paul Lashomb¹

¹ *Baylor University*

Corresponding Author: paul_lashomb@baylor.edu

In Lattice QCD, solutions of the quark matrix M can be difficult to obtain via Krylov methods due to the low-lying eigenvalue distribution. Polynomial preconditioning can be used to speed up the convergence of Krylov solvers by shifting the low-lying eigenvalues away from the origin. New polynomial preconditioners have been previously developed to achieve high-degree polynomials and an application of these high-degree polynomials in the context of noise theory will be the subject of this talk. Measurements in Lattice QCD, particularly those involving disconnected loops, produce a significant amount of noise. Noise subtraction methods have previously been developed to reduce

the noise from such measurements. Some of these methods involve producing polynomials as approximate matrix inverses, but only low-degree polynomials have been applied to these methods. The new method of constructing polynomials has been applied to these methods to allow for much higher degree polynomials to be achieved, theoretically improving the approximation as a matrix inverse in the subtraction methods, the results of which will be discussed.

We report the first search of CP violation using T-odd triple product asymmetries and the most precise branching fraction measurement for the singly Cabibbo suppressed decay $D^0 \rightarrow K_s^0 K_s^0 \pi^+ \pi^-$. These results will be obtained using 922 fb⁻¹ data sample that was collected with the Belle detector at the KEKB asymmetric energy e^+e^- collider. The branching fraction is measured relative to the normalization channel $D^0 \rightarrow K_s^0 \pi^+ \pi^-$. Charm decays are expected to have very small CP violation in the standard model, this makes CP violation searches in charm decays an excellent probe of physics beyond the standard model. We have probed the asymmetries in the observable $C_T = \vec{P}_{K_s^0} \cdot (\vec{P}_{\pi^+} \times \vec{P}_{\pi^-})$ for D^0 and \bar{D}^0 decays. Looking at the difference of T-odd asymmetries between CP conjugate D^0 and \bar{D}^0 decays provides us a CP asymmetry observable free from strong interaction effects.

Di-Higgs observation as a probe of Higgs self-coupling

Author: Amit Adhikary¹

¹ Centre for High Energy Physics, Indian Institute of Science, Bangalore 560012, India

Corresponding Author: amitadhikary@iisc.ac.in

A direct measurement of the Higgs self coupling is very crucial to understand the nature of electroweak symmetry breaking. This requires an observation of production of Higgs boson pair, which suffers from very low event rate even at the current LHC run. In our work, we study the prospects of observing the Higgs pair production at the high luminosity run of the 14 TeV LHC (HL-LHC) and

also the proposed high energy upgrade of the LHC at 27 TeV, namely, HE-LHC. For the HL-LHC study, we choose multiple final states based on the event rate and cleanliness, namely, $b\bar{b}\gamma\gamma$, $b\bar{b}\tau^+\tau^-$, $b\bar{b}WW^*$, $WW^*\gamma\gamma$ and $4W$ channels and do a collider study by employing a cut-based as well as multivariate analyses using the Boosted Decision Tree (BDT) algorithm. In case of HE-LHC study, we select various di-Higgs final states based on their cleanliness and production rates, namely, $b\bar{b}\gamma\gamma$, $b\bar{b}\tau^+\tau^-$, $b\bar{b}WW^*$, $WW^*\gamma\gamma$, $b\bar{b}ZZ^*$ and $b\bar{b}\mu^+\mu^-$ channels. We adopt multivariate analyses using BDT algorithm, the XGBoost toolkit and Deep Neural Network (DNN) for the signal-background discrimination. Also, we perform a study on the ramifications of varying the self-coupling of Higgs boson from its Standard Model (SM) value.

¹ *IIT Kharagpur*

² *Indian Institute of science (IN)*

Corresponding Author: tarak.maity.physics@gmail.com

The discovery of diffuse sub-PeV gamma-rays by the Tibet ASy collaboration promises to revolutionize our understanding of the high-energy astrophysical universe. It has been shown that this data broadly agrees with prior theoretical expectations. In this talk, We will discuss the impact of this discovery on a well-motivated new physics scenario: PeV-scale decaying dark matter (DM). Considering a wide range of final states in DM decay, a number of DM density profiles, and numerous astrophysical background models, we find that this data provides the most stringent limit on DM lifetime for various Standard Model final states. In particular, we find that the strongest constraints are derived for DM masses in between a few PeV to few tens of PeV. Near future data of these high-energy gamma-rays can be used to discover PeV-scale decaying DM.

Vertex Reconstruction with ATLAS Inner Detector and Inner Tracker

Author: Ke Li¹

¹ *University of Washington (US)*

Corresponding Author: ke.li@cern.ch

A rate of 60 or more inelastic collisions per beam crossing was observed during LHC Run 2 and even higher vertex density, or pile-up, is expected in Run 3 and Run 4. Efficient and precise reconstruction of the primary vertex in proton-proton collision is essential for determining the full kinematic

properties of the hard-scatter event and of soft interactions. Increasing instantaneous luminosity poses a challenge for primary vertex reconstruction in ATLAS. To meet this challenge, ATLAS has developed a global approach to vertex finding and fitting, allowing vertices to compete for the association of nearby tracks. This talk will summarize the strategy and performance of this new vertex reconstruction software for Run 3, and the expected performance with Inner Tracker (ITk) upgrade for Run4.

Automated tools for the computation of amplitudes and cross sections have become the backbone of phenomenological studies beyond the standard model. We present the latest developments in MadDM, a calculator of dark matter observables based on MadGraph5_aMC@NLO. The new version enables the fully automated computation of loop-induced annihilation processes, relevant for indirect detection of dark matter. Of particular interest is the electroweak annihilation into γX , where $X = \gamma, Z, h$ or any new unstable particle even under the dark symmetry. These processes lead to the sharp spectral feature of monochromatic gamma lines: a smoking-gun signature for dark matter annihilation in our Galaxy. MadDM provides the predictions for the respective fluxes near Earth and derives constraints from the γ -ray line searches by Fermi-LAT and HESS. As an application, we present the implications for the parameter space of the Inert Doublet model and a top-philic t -channel mediator model.

UV-completion in Particle Theory with Infinite Derivatives: Conformal Invariance, Laboratory and Cosmological Implications

Author: Anish Ghoshal¹

¹ University of Warsaw, Poland

Corresponding Author: anishghoshal1@gmail.com

We will discuss constructions of string-inspired higher-derivative non-local extension of particle theory which is explicitly ghost-free. Showing quantum loop calculations in the weak perturbation

limit we explore the implications on the hierarchy problem and vacuum instability problem in Higgs theory. Then we will discuss the abelian and non-abelian model-building in infinite derivative QFT in 4-D which naturally leads to the predictions of dynamical conformal invariance in the UV at the quantum level due to the vanishing of the β -functions above the energy scale of non-locality M . The theory remains finite and perturbative upto infinite energy scales resolving the issue of Landau poles. We move on to the implications of infinite-derivatives in LHC, dark matter, astrophysical and inflationary observables and comment on constraints on the scale M and dimensional transmutation of the scale M . Next we will discuss the strong perturbation limit and show that mass gap that arises due to the interactions in the theory gets diluted in the UV due to the higher-derivatives again reaching a conformal limit in the asymptotic regions both for the scalar field case and Yang-Mills cases. For the Yang-Mills, the gauge theory is confining without fermions and we explore the exact beta-function in the theory. We conclude by summarising the non-locality as a framework UV-completion in particle theory and gravity and the road ahead for its fate with model-building with respect to BSM physics, particularly neutrinos, dark matter and axions.

The stringent constraints from the direct searches for exotic scalars at the LHC as well as indirect bounds from flavour physics measurements have imposed severe restrictions on the parameter space of new physics models featuring extended Higgs sectors. In the Type-II 2HDM, this implies a lower bound on the charged Higgs masses of $\mathcal{O}(600 \text{ GeV})$. In this work we analyse the phenomenology of a Z_3 HDM in the alignment limit focusing on the impact of flavour physics constraints on its parameter space. We show that the couplings of the two charged Higgs bosons in this model feature an additional suppression factor compared to Type-II 2HDM. This gives rise to a significant relaxation of the flavour physics constraints in this model, allowing the charged Higgs masses to be as low as $\mathcal{O}(200 \text{ GeV})$. We also consider the constraints coming from precision electroweak observables and the observed diphoton decay rate of the 125 GeV Higgs boson at the LHC. The bounds coming from the direct searches of nonstandard Higgs bosons at the LHC, particularly those from resonance searches in the ditau channel, prove to be very effective in constraining this scenario further.

When FIMPs Decay into Neutrinos: The Neff Story

Author: Nashwan Sabti^{None}

Corresponding Author: nashwan.sabti@kcl.ac.uk

The existence of feebly interacting massive particles (FIMPs) could have significant implications on the effective number of relativistic species N_{eff} in the early Universe. In this work, we investigate in detail how short-lived FIMPs that can decay into neutrinos affect N_{eff} and highlight the relevant effects that govern its evolution. We show that even if unstable FIMPs inject most of their energy into neutrinos, they may still decrease N_{eff} , and identify neutrino spectral distortions as the driving power behind this effect. As a case study, we consider Heavy Neutral Leptons (HNLs) and indicate which regions of their parameter space increase or decrease N_{eff} . Moreover, we derive bounds on the HNL lifetime from the Cosmic Microwave Background and comment on the possible role that HNLs could play in alleviating the Hubble tension.

Charged Particle Electric Dipole Moment Measurements at Storage Rings

Author: Jamal Slim¹

¹ *RWTH Aachen University*

Corresponding Author: slim@physik.rwth-aachen.de

The searches for permanent Electric Dipole Moments (EDMs) of elementary particles constitute one of the most powerful tools to probe physics beyond the Standard Model (SM). The existence of EDM can provide an explanation of the dominance of matter over antimatter in the universe which still is considered as one of the most puzzling questions in physics.

The JEDI Collaboration is conducting experimental EDM searches on protons and deuterons at the Cooler Synchrotron (COSY) storage ring at Forschungszentrum Jülich (Germany).

This talk will report on some of the major milestones achieved so far by the the JEDI Collaboration, which in many aspects were world-first achievements including some intermediate and preliminary results of the last presursor EDM experiment conducted on deuterons. Furthermore, an overview of the activities towards a prototype ring of the newly formed CPEDM collaboration will also be briefly presented.

Do neutrinos have sizable self-interactions? This fundamental question, whose answer directly affects future precise astrophysical and cosmological observations, is notoriously difficult to answer with laboratory experiments. For the last years, neutrino telescopes have been identified as unique tools to explore neutrino self-interactions. The actual discovery of astrophysical neutrinos and the advent of future neutrino telescopes, together with a more precise understanding of neutrino masses from laboratory and cosmological probes, calls for a robust theoretical description of the underlying particle physics and its connections with other neutrino observables. In this work, we set up such theoretical framework for present and future studies. We quantify the relevance of previously ignored effects, and we clarify the interplay with other experimental probes of neutrino properties. These directly affect the interpretation of present data in terms of self-interactions, as well as the testability of current “hints” in future facilities. After applying our formalism, we find that current IceCube data shows no evidence of neutrino self-interactions, and it is beginning to exclude self-interactions that have been argued to affect cosmological parameter extraction (most notably H_0). Furthermore, our results show that the future IceCube Gen2 observatory should be sensitive to many cosmologically relevant neutrino self-interaction models.

Radiative M1 Decays of Heavy Flavor bottom Baryons in Effective Mass Scheme

Authors: Avijit Hazra¹; Saheli Rakshit²; Rohit Dhir¹

¹ SRM Institute of Science and Technology

² Florida State University

Corresponding Author: avijithr@srmist.edu.in

We study flavor-conserving M1 radiative decays of heavy flavor bottom baryons in the framework of Effective Mass Scheme (EMS) within the quark model. The intent of the EMS lies in the fact that the masses of the quarks inside the baryon are modified as a consequence of one-gluon exchange interaction with the spectator quarks and it treats all the quarks at the same footing. The baryon mass can be written as the sum of the constituent quark masses and the spin-dependent hyperfine interaction among them. We show that EMS can successfully describe the masses and the magnetic moments, transition moments, and radiative decay widths of the lowest-lying singly heavy flavor baryons in a parameter independent way. The exchange contribution is worked out through interaction terms b_{ij} from the recently observed experimental masses for the heavy flavored charm and bottom baryons for the calculation of effective quark masses. We then compute the magnetic and transition moments of ground state $J^P = (1/2)^{+}$ and $J^P = (3/2)^{+}$, and $(1/2)^{+} \rightarrow (1/2)^{+}$, $(3/2)^{+} \rightarrow (1/2)^{+}$, and $(3/2)^{+} \rightarrow (1/2)^{+}$ heavy flavor charm and bottom baryon states. Finally, we make sturdy model independent predictions for radiative M1 decay widths of heavy flavored baryons. The radiative transitions between the states occur mainly through the M1-type, while there are negligible contributions from E2-type transitions, which are therefore ignored. We also extend our analysis to the triply heavy charm and bottom baryons.

Neutrinos / 340**Cosmogenic background suppression at the ICARUS using a concrete overburden****Author:** Biswaranjan Behera¹¹ *Colorado State University***Corresponding Author:** bishu@colostate.edu

The ICARUS detector will search for LSND like neutrino oscillations exposed at shallow depth to the FNAL BNB beam in the context of the SBN program. In the approved FNAL SBN experiment the impact of cosmic rays is mitigated by a 4π Cosmic Ray Tagger (CRT) detector encapsulating the TPCs inside the pit and by a ~ 3 m concrete overburden both for the near and the far detectors. Cosmic backgrounds rejection is particularly relevant for the ICARUS detector. Due to its larger size and distance from target compared to SBND, in ICARUS the neutrino signal/cosmic background ratio is 40 times more unfavorable with in addition a greater than 3 times larger out-of-spill comics rate. In this talk, I will be addressing the question of a problematic background to genuine neutrino events especially into the electron neutrino appearance analysis by a detailed MonteCarlo calculation of the cosmic rays crossing the ICARUS detector.

Towards Designing and Exploiting Generative Networks for Neutrino Physics Experiments using Liquid Argon Time Projection Chambers

Authors: Nikita Saxena¹; Paul Lutkus¹; Shuchin Aeron¹; Taritree Wongjirad¹

¹ *Tufts University*

Corresponding Author: nikit.saxena0209@gmail.com

We put forth a technique to generate images of particle trajectories (particularly electrons and protons) in a liquid argon time projection chamber (LArTPC). LArTPCs are a type of particle physics detector used by several current and future experiments focused on studies of the neutrino. We implement a quantized variational autoencoder and an autoregressive model which produces images conditioned on momentum with LArTPC like features. In this paper, we adopt a hybrid approach to generative modeling via combining the decoder from the autoencoder together with an explicit generative model for the latent space to produce momentum-conditioned images of particle trajectories in a LArTPC.

Transitioning Dark Sectors and the Hubble Tension

Author: Melissa Joseph¹

Co-authors: Asher Berlin²; Martin Schmaltz ; Neal Weiner²; Daniel Aloni³

¹ *Boston University*

² *NYU*

³ *Weizmann institute*

Corresponding Author: mjoseph2@bu.edu

I will discuss the implications of self-interacting dark-sectors with light degrees of freedom and mass thresholds on early universe physics. Such models exhibit a relative increase in the energy density of the dark sector when the temperature crosses a mass threshold. Of special interest are models with mass thresholds below $\mathcal{O}(\text{MeV})$. In this region of parameter space, the transition (increase in energy density) occurs after BBN, allowing for $N_{\text{eff}} > 3$ and consequently a larger value of H_0 . Additionally, the transition occurs during the epochs probed by cosmological data. I will talk about the cosmological constraints on these models using the most recent data including the 2018 Planck CMB spectra, baryon acoustic oscillation (BAO) data and local measurements of the Hubble constant. The analysis shows a preference for a transition at the KeV scale and we find that these models can alleviate the H_0 tension allowing for $H_0 = 71.4$.

T2K recent results and future prospects

Author: Ciro Riccio¹

¹ *Stony Brook University (US)*

Corresponding Author: ciro.riccio@cern.ch

T2K (Tokai to Kamioka) is a Japan based long-baseline neutrino oscillation experiment designed to measure (anti-)neutrino flavor oscillations. A neutrino beam peaked around 0.6 GeV is produced in Tokai and directed toward the water Cherenkov detector Super-Kamiokande, which is located 295 km away. A complex of near detectors is located at 280 m and is used to constrain the flux and cross-section uncertainties. In 2014, T2K has started a campaign to measure the phase δ_{CP} , an unknown element of the Pontecorvo-Maki-Nakagata-Sakata matrix, that can provide a test of the violation or conservation of the CP symmetry in the lepton sector. To achieve this goal, T2K is taking data with a neutrino and antineutrino enhanced beam investigating asymmetries in the electron neutrino and antineutrino appearance probabilities. The most recent results showed that the CP-conserving cases are excluded at 90% confidence level. One of the largest systematic uncertainties affecting neutrino oscillation measurements comes from limited knowledge of (anti-)neutrino-nucleus interactions. The T2K experiment has a wide range of programs measuring neutrino interaction cross-section using detectors in its near detector complex. In this talk an overview of the latest T2K neutrino oscillation and cross-section measurements are presented. An intense program of upgrades is ongoing and promises to improve the sensitivities of the experiment. It will be discussed in some detail along with the future prospects of the experiment.

One-loop determinant for massive vector field in large dimension limit

Authors: Diana Vaman¹; Yuchen Du¹

¹ *University of Virginia*

Corresponding Author: yd3gh@virginia.edu

We derive an expression for the one-loop determinant of the massive vector field in the Anti-de Sitter black brane geometry with large dimension limit. We utilize the Denef, Hartnoll and Sachdev method, which constructs the one-loop determinant from the quasinormal modes of the field. The large dimension limit decouples the equations of motion for different field components, and also selects a specific set of quasinormal modes that contribute to the non-polynomial part of the one-loop determinant. We hope this result can provide some useful information even when the number of dimension D is finite, since it's the leading order contribution when we treat D as a parameter and do an expansion in terms of $1/D$.

Neutrinos / 352**Data-Driven cross checks for electron neutrino selection efficiency in NOvA****Author:** Anna Hall¹¹ *University of Virginia*

Corresponding Author: ah4gb@virginia.edu

NOvA is a long-baseline neutrino oscillation experiment, designed to make precision neutrino oscillation measurements using ν_μ disappearance and ν_e appearance. It consists of two functionally equivalent detectors and utilizes the Fermilab NuMI neutrino beam. NOvA uses a convolutional neural network for particle identification of ν_e events in each detector. As part of the validation process of this classifier's performance, we apply a data-driven technique called Muon Removal. In a Muon-Removed Electron-Added study we select ν_μ charged current candidates from both data and simulation in our Near Detector and then replace the muon candidate with a simulated electron of the same energy. In a Muon-Removed Decay-in-Flight study we remove the muonic hits from events where cosmic muons entering the detector have decayed in flight, resulting in samples of pure electromagnetic showers. Each sample is then evaluated by our classifier to obtain selection efficiencies. Our recent analysis found agreement between the selection efficiencies of data and simulation within our uncertainties, showing that our classifier selection is generally robust in ν_e charged current signal selection.

Simulation of the Cosmic Ray Background for the Mu2e Experiment

Author: Yuri Oksuzian¹

¹ *Argonne National Lab*

Corresponding Author: yoksuzian@anl.gov

The Mu2e experiment is designed to search for New Physics in an extremely rare process of muon to electron neutrino-less conversion. The Mu2e sensitivity to New Physics heavily relies on suppressing all the background sources to a fraction on event. The dominant background at Mu2e originates from cosmic ray (CR) muons that interact or decay in the detector solenoid and produce a signal-like electron. Mu2e expects to observe one CR background a day. In order to reach the proposed sensitivity, Mu2e is designed to suppress the CR background by 4 orders of magnitude, using the Cosmic Ray Veto detector that covers over 300 m^2 . The precision CR background prediction is an essential component of Mu2e's success. We will report on CR background estimates at Mu2e modeled by CRY cosmic ray generator and using the detector response simulated with the Geant4 framework.

Neutron beam test with 3D-projection scintillator tracker prototypes for long-baseline neutrino oscillation experiments at Los Alamos National Laboratory

Author: Andriasetra Sitraka¹

¹ *South Dakota School of Mines and Technology*

Corresponding Author: andriasetasitraka@gmail.com

Long-baseline neutrino oscillation experiments such as T2K (Tokai-to-Kamioka) and DUNE (Deep Underground Neutrino Experiment) rely on models of neutrino interaction on nuclei. A major systematic uncertainty in the model of neutrino interaction comes from the blindness of the detector to the neutrino-induced neutrons in the final state. The 3D-projection scintillator tracker, which consists of a large number of 1 cm x 1 cm x 1 cm plastic scintillator cubes with three orthogonal wavelength shifting fibers crossing through each cube is proposed as part of the near detectors of T2K upgrade and the DUNE. Nanosecond timing resolution and fine granularity will allow to the 3D-projection scintillator tracker the measurement of neutron kinetic energy in the neutrino interaction on an event-by-event basis. Two prototypes have been assembled and exposed to neutron beam test in Los Alamos National Laboratory in December 2019 and 2020 to fully demonstrate the neutron detection capability and optimize the tracker design. In this presentation, the prototype detector assembly, beamline setup and the detector calibration using LED pulses and cosmics muons will be detailed.

The MIP Timing Detector (MTD) is a new sub-detector planned for the Compact Muon Solenoid (CMS) experiment at CERN, aimed at maintaining the excellent particle identification and reconstruction efficiency of the CMS detector during the High Luminosity LHC (HL-LHC) era. The MTD will provide new and unique capabilities to CMS by measuring the time-of-arrival of minimum ionizing particles with a resolution of 30 - 40 ps at the beginning of HL-LHC operation. The information provided by the MTD will help disentangle ~ 200 nearly simultaneous pileup interactions occurring in each bunch crossing at LHC by enabling the use of 4D reconstruction algorithms. The central Barrel Timing Layer (BTL) of the MTD uses a sensor technology consisting of LYSO:Ce crystal bars readout by SiPMs, one at each end of the bar. In this talk, we present an overview of the MTD BTL design and the recent test beam results demonstrating the achievement of the target time resolution of about 30 ps.

Charged Higgs Prospects In Extended Gauge Models

Author: Agnivo Sarkar¹

Co-authors: Baradhvaj Coleppa¹; Gokul B. Krishna¹

¹ IIT Gandhinagar

Corresponding Author: agnivo.sarkar@iitgn.ac.in

In this talk, we explore the collider phenomenology of the charged Higgs boson in the context of a Beyond Standard Model scenario with extended gauge and scalar sector. Because of the intricate pattern of symmetry breaking, the charged Higgs can simultaneously decay via heavy gauge boson mediated channels ($W'Z/WZ'$) along with the traditional SM decay modes. Our goal here is to formulate the search strategy of the H^\pm in the channel $\sigma(gb \rightarrow H^\pm t)\mathcal{BR}(H^\pm \rightarrow W'Z)$. Since the W'_μ boson in this model does not couple to SM fermions in tree level, it opens up interesting cascade decay chain: $H^\pm \rightarrow W'Z \rightarrow W^\pm ZZ$. As a result the charged Higgs can be discovered in the final state with multiple hard leptons and/ or b-quarks which future LHC experiments with sufficiently large luminosity (say, $\mathcal{L} = 1000 fb^{-1}$) can probe.

Characterization of Multi-Pixel Photon Counters for the T2K near detector upgrade

Author: Shih-Kai Lin¹

¹ Louisiana State University

Corresponding Author: shihkailin1@lsu.edu

T2K is a long-baseline accelerator neutrino oscillation experiment which has precisely measured neutrino oscillation parameters and hinted at a significant matter-antimatter asymmetry in the lepton sector. In view of the upcoming program of upgrades of the beam intensity, a novel plastic-scintillator detector for the T2K near detector upgrade, called SuperFGD, is proposed aiming to reduce the statistical and systematic uncertainties of the measurements. The scintillation light from particle interactions in SuperFGD is collected by Multi-Pixel Photon Counter (MPPC), a solid state photomultiplier with high internal gain. In this talk, the characterization of the MPPC sensors is presented.

Dark Matter Absorption via Electronic Excitations Revisited

Author: Tanner Trickle¹

Co-authors: Andrea Mitridate ; Zhengkang Zhang ²; Kathryn Zurek ²

¹ *California Institute of Technology*

² *Caltech*

Corresponding Author: ttrickle17@gmail.com

Absorption of dark matter (DM) allows direct detection experiments to probe a broad range of DM candidates with masses much smaller than kinematically allowed via scattering. It has been known for some time that for vector and pseudoscalar DM the absorption rate can be related to the target's optical properties, i.e. the conductivity/dielectric. However this is not the case for scalar DM, where the absorption rate is determined by a, formally, NLO operator which does not appear in the photon absorption process. Therefore the absorption rate must be determined by other methods. We use a combination of first principles numeric calculations and semi-analytic modeling to compute the absorption rate in silicon, germanium and a superconducting aluminum target. We also find good

agreement between these approaches and the data-driven approach for the vector and pseudoscalar DM models.

Predictions for the Leptonic Dirac CP-Violating Phase

Author: Alexander Stuart¹

¹ *Universidad de Colima*

Corresponding Author: astuart@ucol.mx

We explore the theoretical constraints on the observable parameters of neutrino mixing on predictions for the leptonic Dirac CP-violating phase within a class of theoretical models that include a single source of CP violation due to charged lepton corrections. As a means to enforce unitarity of the lepton mixing matrix, we assume specific ansatzes for the probability distributions of the continuous input parameters and calculate the distributions of the observable lepton mixing parameters. The approach guarantees that a physically meaningful prediction for the most likely values for the leptonic Dirac CP-violating phase within these simple scenarios is automatically obtained.

The Heavy Photon Search experiment: summary and recent developments for the 2019 Data Run

Author: Alic Spellman¹

Co-author: Pierfrancesco Butti²

¹ *University of California, Santa Cruz*

² *Stanford University*

Corresponding Author: alsPELLM@ucsc.edu

New physics beyond the Standard Model (SM) could be responsible for the presence of Dark Matter in the Universe. A hidden, or “dark”, sector interacting with SM particles via new force carriers is a natural scenario to explain the features of Dark Matter. In the last decade, growing interest has been dedicated to the search for dark sectors with force carriers in the MeV-GeV mass range. A well motivated model envisions the presence of a $U(1)$ gauge boson, the heavy photon A' , whose existence can be probed with fixed-target experiments at accelerators.

The Heavy Photon Search Experiment (HPS) at the Thomas Jefferson National Accelerator Facility (JLAB) searches for heavy photons and other new force carriers that are produced via electro-production and decay visibly to electron-positron pairs. This talk presents recent developments in reconstruction and calibration of the 2019 Data Run at 4.55 GeV, including performance of the newly adopted Kalman Filter track reconstruction algorithm.

Latest Reactor Antineutrino Spectrum and Boosted Dark Matter Results from PROSPECT

Author: Pierce Weatherly¹

¹ *Drexel University*

Corresponding Author: pbw27@drexel.edu

PROSPECT is a reactor antineutrino experiment designed to search for short-baseline sterile neutrino oscillations and to perform a precise measurement of the U-235 reactor antineutrino spectrum. The PROSPECT detector collected data at the High Flux Isotope Reactor (HFIR) at the Oak Ridge National Laboratory, with the ~4-ton volume covering a baseline range of 7-9m. To operate in this environment with tight space constraints, limited overburden, and the possibility of reactor-correlated backgrounds, the PROSPECT AD incorporates design features that provide excellent background rejection. These include detector segmentation and the use of Li-6 doped liquid scintillator with high light yield, world-leading energy resolution, and good pulse-shape discrimination properties. This talk will describe the operations of PROSPECT at HFIR and report on the latest results from the antineutrino spectrum measurement of U-235 fissions. Additionally, the limits from searches by PROSPECT for sub-GeV boosted dark matter upscattered by cosmic rays will be reported.

Physics Opportunities with a PROSPECT Upgrade

Author: Rachel Carr¹

¹ *Massachusetts Institute of Technology*

Corresponding Author: recarr@mit.edu

The Precision Reactor Oscillation and Spectrum Experiment, PROSPECT, at the High Flux Isotope Reactor at ORNL has made world-leading measurements of reactor antineutrinos at short baselines. PROSPECT provides some of the best limits on eV-scale sterile neutrinos, has made a precision measurement of the reactor antineutrino spectrum of ²³⁵U from a highly-enriched uranium reactor, and has demonstrated the observation of reactor antineutrinos in an aboveground detector with good energy resolution and well-controlled backgrounds. The PROSPECT collaboration is now preparing an upgraded detector, PROSPECT-II, to probe yet unexplored parameter space for sterile neutrinos and fully resolve the Reactor Antineutrino Anomaly, a longstanding puzzle in neutrino physics. By pressing forward on the world's most precise measurement of the ²³⁵U antineutrino spectrum and measuring the absolute flux of antineutrinos from ²³⁵U, PROSPECT-II will sharpen a tool with potential value for basic neutrino science, nuclear data validation, and nuclear security applications. An additional deployment at a low-enriched uranium reactor would expand this contribution with complementary measurements of the antineutrino yield from other fission isotopes. PROSPECT-II provides a unique opportunity to continue the study of reactor antineutrinos at short baselines in the US while training a new cohort of neutrino physicists.

Measurement of the Charged Current ν_e Interaction Cross Section on Water with the T2K π^0 Detector

Author: Yue Wang¹

¹ *Stony Brook University (US)*

Corresponding Author: yue.wang.4@stonybrook.edu

The T2K experiment is a long base-line neutrino oscillation experiment which is designed to measure ν_μ disappearance and ν_e appearance from the ν_μ beam produced from a 30 GeV proton beam at J-PARC (Japan Proton Accelerator Research Complex). It consists of the J-PARC accelerator, a near detector complex (ND280) and a far detector (Super-Kamiokande). In order to achieve more precise ν_e appearance measurements and to explore CP violation in the neutrino sector, we need to improve our knowledge on ν_e interactions and determine contamination of ν_e in the ν_μ beam better. The ν_e component in the beam that is intrinsic is the main background in the ν_e appearance measurement. Besides, a large systematic uncertainty in T2K ν_e appearance observation comes from uncertainties related with the neutrino cross-section modeling. Since the far detector is a water Cherenkov detector, neutrino interaction measurements on water are important to constrain the neutrino cross-section systematic uncertainties. The design of π^0 Detector (POD), a component of ND280, which includes fillable water targets, allows us to measure on-water neutrino interaction cross-section. We developed a cross-section measurement method utilizing Markov-Chain Monte Carlo. In this talk, I will present the method and fake data study results of the charged current ν_e interaction cross section on-water.

$U(1)_{T3R}$ extension of Standard Model

Authors: Bhaskar Dutta¹; Sumit Ghosh²; Jason Kumar^{None}; Peisi Huang³

¹ *Texas A&M University*

² *Texas A & M University*

³ *University of Nebraska-Lincoln*

Corresponding Author: ghosh@tamu.edu

Scenarios in which right-handed light Standard Model fermions couple to a new gauge group, $U(1)_{T3R}$ can naturally generate a sub-GeV dark matter candidate. But such models necessarily have large couplings to the Standard Model, generally yielding tight experimental constraints. We show that the contributions to $g_\mu - 2$ from the dark photon and dark Higgs largely cancel out in the narrow window where all the experimental constraints are satisfied, leaving a net correction which is consistent with recent measurements from Fermilab. These models inherently violate lepton universality, and UV completions of these models can include quark flavor violation which can explain $R_{K^{(*)}}$

anomalies as observed at the LHCb experiment after satisfying constraints on $Br(B_s \rightarrow \mu^+ \mu^-)$ and various other constraints in the allowed parameter space of the model. This scenario can be probed by FASER, SeaQuest, SHiP, LHCb, Belle, etc.

Cosmological collider physics beyond the inflationary Hubble scale

Authors: Arushi Bodas^{None}; Raman Sundrum^{None}; Soubhik Kumar¹

¹ *UC Berkeley*

Corresponding Author: arushib@terpmail.umd.edu

The cosmological collider physics program aims at probing particle physics at energies as high as the inflationary Hubble scale, $H < 10^{13}$ GeV, using precision measurements from CMB, large scale structure surveys, and 21-cm cosmology. Heavy particles produced during inflation can impart unique correlations in the density fluctuations across the sky, leading to non-gaussianity (NG) in the cosmological observables. This presents a unique opportunity for the “direct detection” of particles with masses as large as H . However, the strength of this signal drops exponentially due to a Boltzmann-like factor as masses exceed H . In this talk, I will discuss a mechanism that overcomes this suppression and broadens the scope of cosmological collider physics, focusing on the case of a massive complex scalar field. The mechanism allows us to harness large kinetic energy of the inflaton to produce particles with masses as large as $\sim 60H$. I will show that NG with $f_{\text{NL}} \sim \text{calO}(0.01 - 10)$ can be obtained, and delineate a procedure to infer the mass of the heavy field from the signal.

Searching for Long-Lived Dark Photons with the Heavy Photon Search Experiment

Author: Matthew Solt¹

¹ *University of Virginia*

Corresponding Author: gtf9nz@virginia.edu

The Heavy Photon Search experiment searches for electro-produced dark photons using an electron beam provided by CEBAF at the Thomas Jefferson National Accelerator Facility. HPS looks for dark photons through two distinct methods –a resonance search in the $e+e$ invariant mass distribution above the large QED background for large dark photon-SM particles couplings, and a displaced vertex search for long-lived dark photons for small couplings. An engineering run in 2016 obtained 5.4 days (92.5 mC) of data using a 2.3 GeV, 200 nA electron beam, and both sets of analysis are unblinded and nearing completion. Even though the result from the 2016 displaced vertex search (which will be the focus of the talk) is insufficient to set physically meaningful limits, it demonstrated the full functionality of the experiment, including both signal expectation and background mitigation, that

will enable probing unexplored parameter space with existing data and future, higher luminosity runs.

In recent years, deep learning has played an emerging role in event reconstruction for neutrino experiments using liquid argon TPCs (LArTPCs), a high-precision particle imaging technology. Several algorithms have been developed to infer the 3D location of charge depositions in the detector. Furthermore, the development of 2D pixel-readouts naturally provides 3D positions. Therefore, there is a growing need for reconstruction algorithms that work on 3D image data. We report on our effort to develop a 3D particle instance identifier based on an extension of the Mask Region-Convolutional Neural Network (Mask-RCNN). Mask-RCNN, originally an algorithm for 2D images, is widely used in computer vision problems and has three main goals: to identify the location of each object in an image using a bounding box, to classify an object in each bounding box, and to cluster each object by determining its pixel boundaries using a mask. Inspired by the conversion to 3D and our sparse dataset, we introduce a sparse bounding box proposal method that greatly reduces inefficiencies associated with box predictions in 3D. We also describe our future plans to continue development on the masking network to explore using this architecture for particle clustering.

Higgs & Electroweak Physics / 373**Strong First-Order Electroweak Phase Transitions in the Standard Model with a Singlet Extension****Author:** Anthony Hooper¹**Co-author:** Peisi Huang¹¹ *University of Nebraska-Lincoln***Corresponding Author:** anthony.hooper@huskers.unl.edu

A common assumption about the early universe is that it underwent an electroweak phase transition (EWPT). Though the standard model (SM) is able to restore the electroweak symmetry through a smooth cross over PT, we require a strongly first-order PT to ensure electroweak baryogenesis, requiring us to look at new physics beyond the SM. The simplest case to extend the SM is to add a real singlet field, which allows for a first-order EWPTs (FOEPT) to occur.

Starting with the most general higgs+singlet lagrangian, we fixed four of its coupling constants as functions of the three quartics, the singlet and higg's mass and vacuum expectation value, whose range of values had more experimental motivation than the former. We ran a Monte-Carlo scan over these five free parameters, requiring a FOEPT and a PT strength of $\epsilon > 1.3$. These points were then passed through the FindBounce package to calculate the nucleation temperature. The resulting parameter space was studied, most notably, we observed the ratio of the triple higgs coupling to the SM value ($\kappa = \lambda_3/\lambda_3$) take on values between 0.5 and 2.7. The possible values of λ_3 could serve as motivation for future collider experiments to improve sensitivity in this range when looking at the cross sections of \rightarrow versus λ_3 .

Searches for new resonant phenomena in final states with two quarks using the ATLAS detector

Author: Elham E Khoda¹

¹ *University of Washington (US)*

Corresponding Author: elham.e.khoda@cern.ch

Many theories beyond the Standard Model predict new phenomena, such as Z' and vector-like quarks, in final states containing bottom- or top-quarks. It is challenging to reconstruct and identify the decay products and model the major backgrounds. Nevertheless, such final states offer great potential to reduce the Standard Model backgrounds due to their characteristic decay signature. The latest search in the two quark final states using the full Run-2 (139 fb^{-1}) proton-proton collision data collected at a center-of-mass energy of $\sqrt{s} = 13 \text{ TeV}$ with the ATLAS detector will be presented. In particular, this presentation will summarize the recent results of dijet and top-antitop resonance searches in the hadronic top-quark final state. This talk will also highlight associated improvements coming from deep learning-based b -quark and top-quark identification techniques. Furthermore, the interpretations of these results in the context of s -channel dark matter mediator models will be discussed.

Gas-rich dwarf galaxies as powerful sub-GeV dark matter detectors

Authors: Digvijay Wadekar¹; Glennys Farrar¹

¹ *NYU*

Corresponding Author: digvijay.wadekar@gmail.com

Dwarf galaxies are relatively pristine objects for testing dark matter microphysics due to weak baryonic feedback in them. We use a particular class of dwarfs which are gas-rich to probe DM interactions with ordinary matter. We require the rate of heat exchange between DM and gas to not exceed the low radiative cooling rate of the gas. This gives strong constraints on popular DM models: our constraints on axion like particles (ALPs), millicharged DM and magnetic PBHs are complementary and comparable to other probes, while they are the strongest to date for dark photon DM for $10^{-20} < m_{\text{DM}} < 10^{-14} eV$. We therefore show that observations of gas-rich dwarfs from current and upcoming optical and 21cm surveys open a new way to probe physics beyond the standard model.

Search for heavy fermionic partner of the top quark with charge 5/3 in the single leptonic channel using CMS Run 2 Data

Author: Farrah Simpson¹

¹ *Brown University (US)*

Corresponding Author: farrah.simpson@cern.ch

With the discovery of the Higgs boson in 2012 by the CMS and ATLAS experiments, searches for new heavy particles (such as vector-like quarks) have ensued in hope of solving the hierarchy problem. In this talk, I will be discussing the search for the X_{5/3}, a strongly interacting fermionic partner of the top quark with charge +5/3. Left-handed and right-handed coupling of the X_{5/3} to W bosons are considered separately. The search is conducted using the CMS datasets collected in 2017 and 2018. The data were collected at a center-of-mass energy of $\sqrt{s} = 13$ TeV with the CMS detector, corresponding to an integrated luminosity of 41.5 fb⁻¹ (60 fb⁻¹) in 2017 (2018). The search looks for events with pair production of an X_{5/3} and its antiparticle, which subsequently decay to a top quark and W boson. To enhance signal separation, the search is constructed to only look for events where one W boson decays to a lepton and neutrino, while the other three W bosons decay hadronically. Limits on the cross section will be presented and compared to previous results.

Reactor Position Reconstruction Study with PROSPECT

Authors: Diego Camilo Venegas-Vargas¹; Rosa Luz Zamora Peinado²

¹ *University of Tennessee Knoxville/ Oak Ridge National Laboratory*

² *University of Tennessee Knoxville/Oak Ridge National Laboratory*

Corresponding Author: dvenega1@vols.utk.edu

The Precision Reactor Oscillation and Spectrum Experiment (PROSPECT) is an above-ground antineutrino experiment at short baselines located at the High Flux Isotope Reactor (HFIR) at Oak Ridge National Laboratory (ORNL). The PROSPECT detector comprises 4-tons of Li-6 doped liquid scintillator (⁶LiLS) divided into an 11x14 array of optically separated segments. This experiment's physics goals include searching for the existence of sterile neutrinos and precisely measuring the antineutrino energy spectrum. Antineutrinos are detected via the inverse beta decay (IBD) interaction which provides a near-unique space-time correlated signal pair consisting of a positron energy deposition and a delayed neutron capture in the liquid scintillator. The correlation between prompt and delayed pulses/signals is an excellent handle for background suppression. The highly segmented nature of the PROSPECT detector, as well as the double-ended readout structure in each segment, provides good position reconstruction for both prompt and delayed signals. In this talk, I will give an overview of the experiment, as well as current efforts to use the position resolution of the detector and the kinematics of the IBD reaction to study the neutrino directional reconstruction capabilities of PROSPECT.

Electroweak pMSSM Reinterpretation of ATLAS Searches for SUSY

Author: Nupur Oza¹

¹ *Lawrence Berkeley National Lab. (US)*

Corresponding Author: nupoza@sas.upenn.edu

Naturalness suggests that the masses of the lightest electroweak gauginos (electroweakinos) are near the electroweak scale and, as a result, are within the scope of current LHC searches. However, LHC searches have not yet provided evidence of any supersymmetric (SUSY) particles. While exclusion limits for SUSY particles have been commonly reported assuming a simplified model where the branching ratio of targeted decays is 100%, this is not realistic in the minimal supersymmetric standard model (MSSM) and does not represent the effect of a large number of competing production and decay processes. If the decay branching ratios of these particles are lower, however, the reported mass limits are likely to be optimistic.

Focusing on chargino-neutralino production in a conventionally considered scenario where the LSP is bino-like and the next lightest SUSY particle is wino-like, electroweakino decay branching ratio into on-shell SM bosons can be established in terms of electroweak phenomenological MSSM (pMSSM) parameters. This talk will present the dependence of the branching ratios on the electroweak MSSM parameters, restate mass limits from simplified ATLAS searches in terms of the pMSSM, and ultimately, present the implications of a pMSSM based approach to SUSY searches.

The Design and Integrated Performance of SPT-3G

Author: Joshua Sobrin¹

¹ *University of Chicago*

Corresponding Author: joshuasobrin@uchicago.edu

SPT-3G is the third survey receiver operating on the South Pole Telescope dedicated to high-resolution observations of the cosmic microwave background (CMB). Sensitive measurements of the temperature and polarization anisotropies of the CMB provide a powerful dataset for constraining the fundamental physics of the early universe, including models of inflation and the neutrino sector. Additionally, CMB surveys with arcminute-scale resolution are capable of detecting galaxy clusters, millimeter-wave bright galaxies, and a variety of transient phenomena. The SPT-3G instrument provides a significant improvement in mapping speed over its predecessors, SPT-SZ and SPTpol. The broadband optics design of the instrument achieves a 430 mm diameter image plane across observing bands of 95 GHz, 150 GHz, and 220 GHz, with 1.2 arcmin FWHM beam response at 150 GHz. In the receiver, this image plane is populated with 2690 dual-polarization, tri-chroic pixels (~16000 detectors) read out using a 68X digital frequency-domain multiplexing readout system. In 2018, SPT-3G began a multiyear survey of 1500 deg² of the southern sky. I will summarize the unique optical, cryogenic, detector, and readout technologies employed in SPT-3G, and I will report on the integrated performance of the instrument.

RNN-based track finding in the Fermilab Muon g-2 experiment

Author: Emmanouil Kargiantoulakis¹

¹ *Fermi National Accelerator Laboratory*

Corresponding Author: ekargian@fnal.gov

We report on the development of a track finding algorithm for the Fermilab Muon g-2 Experiment's straw tracker using advanced Deep Learning techniques. Taking inspiration from original studies by the HEP.TrkX project, our algorithm relies on a Recurrent Neural Network with bi-directional LSTM layers to build and evaluate track candidates. The model achieves good performance on a 2D representation of the Muon g-2 tracker detector. We will discuss our targets for improving efficiency and performance, and plans towards application on real data via training on a synthetic dataset.

Muon conversions with flavor changing Rayleigh operators

Authors: Cody Grant¹; Alexey Petrov¹

¹ *Wayne State University*

Corresponding Author: codygrant@wayne.edu

Lepton-flavor violating transitions provide excellent tools to probe physics beyond the Standard Model (BSM). Processes such as radiative muon decays or muon conversion on nuclei probe a variety of different operators. We point out that Rayleigh operators that contribute to muon conversion can also be probed in a much simple environment of e+e- collisions. We report on the computation of short and long-distance contributions to those processes.

Improved Background Rate and Coincident Event Removal in SuperCDMS HVeV Run 3

Authors: SuperCDMS Collaboration^{None}; Taylor Aralis¹

¹ *Caltech*

Corresponding Author: tbaralis@gmail.com

The third science run of SuperCDMS HVeV detectors (single-charge sensitive detectors with high Neganov-Trofimov-Luke phonon gain) took place at the NEXUS underground test facility in early 2021, incorporating two important changes to test background hypotheses and enhance sensitivity.

First, this was the first HVeV dataset taken underground (300 mwe) and in a shielded environment. Second, the run utilized three detectors operated simultaneously to identify sources of background events that produce 2 or more electron-hole pairs. We will present preliminary results and interpretation from these tests as well as an estimate of the expected sensitivity of the dataset.

Study of neutrino-nucleus interactions with ANNIE experiment

Author: Venkatesh Veeraraghavan¹

¹ *Iowa State University*

Corresponding Author: venkat@iastate.edu

The Accelerator Neutrino Neutron Interaction Experiment (ANNIE) experiment is a 26-ton gadolinium-loaded water Cherenkov detector located on the Booster Neutrino Beam at Fermilab. The experiment has a two-fold motivation: to perform a physics measurement and to advance new detector technologies. The measurement of final state neutron multiplicity from neutrino interactions in water as a function of momentum transfer will lower systematic uncertainties for future long-baseline neutrino experiments. The experiment is currently commissioning large-area picosecond photodetectors that will improve time and spatial resolution. I will present the current status of the ANNIE experiment along with future plans.

Measurement of $B \rightarrow D^{**}l\nu$ branching fraction using Belle data

Author: Frank Meier¹

¹ *Duke University*

Corresponding Author: frank.meier@duke.edu

There is a significant gap between the inclusive measurement of the $B \rightarrow X_c l \nu$ branching fraction and the sum of the measurements of the exclusive $B \rightarrow X_c l \nu$ channels. The dominant contributions $B \rightarrow D^* l \nu$ and $B \rightarrow D l \nu$ are precisely known but the branching fractions of $B \rightarrow D^{**} l \nu$ have higher uncertainties. Here, the D^{**} is an orbitally excited charmed meson, which can decay into $D^* \pi$ and $D \pi$. The decay $B \rightarrow D^{(*)} \pi \pi l \nu$ with two bachelor pions in the final state has so far only been observed by the Babar collaboration.

Over the course of about 10 years the Belle collaboration has recorded about 772 million $B\bar{B}$ pairs produced in $e^+e^- \rightarrow \Upsilon(4S)$ at the KEKB asymmetric-energy e^+e^- collider. The status of the measurement of the branching fraction of $B \rightarrow D^{(*)} \pi l \nu$ as well as $B \rightarrow D^{(*)} \pi \pi l \nu$ using the full

Belle data sample will be presented. In addition, an analysis of the invariant $D^{(*)}\pi$ mass distribution will be shown.

A cosmological dark matter collider experiment

Author: Francis-Yan Cyr-Racine¹

¹ *University of New Mexico*

Corresponding Author: fycr@unm.edu

Observations of dark matter structure at the smallest scales can tell us about physical processes taking place in the dark sector at very early times. Here, we point out that the presence of light degrees of freedom coupling to dark matter in the early Universe introduces a localized feature in the halo mass function. This leads to a mass function that is distinct in shape than either warm dark matter or cold dark matter, hence distinguishing these models from other leading classes of dark matter theories. We present analytical calculations of these mass functions and show that they closely match N-body simulations results. We briefly discuss how current constraints on the abundance of small-scale dark matter structure do not directly apply to these models due to the multi-scale nature of their mass function.

Search for $B^0 \rightarrow \tau^\pm \ell^\mp$ ($\ell = e, \mu$) with a hadronic tagging method at Belle

Authors: Alan Schwartz¹; Hulya Atmacan²; Kay Kinoshita¹

¹ *University of Cincinnati*

² *University of Cincinnati Main Campus*

Corresponding Author: atmacaha@ucmail.uc.edu

We present a search for the lepton-flavor-violating decays $B^0 \rightarrow \tau^\pm \ell^\mp$, where $\ell = (e, \mu)$, using the full data sample of 772×10^6 $B\bar{B}$ pairs recorded by the Belle detector at the KEKB asymmetric-energy e^+e^- collider. We use events in which one B meson is fully reconstructed in a hadronic decay mode. The τ^\pm lepton is reconstructed indirectly using the momentum of the reconstructed B and that of the ℓ^\mp from the signal decay. We find no evidence for $B^0 \rightarrow \tau^\pm \ell^\mp$ decays and set upper limits on their branching fractions at 90% confidence level of $calB(B^0 \rightarrow \tau^\pm \mu^\mp) < 1.5 \times 10^{-5}$ and $calB(B^0 \rightarrow \tau^\pm e^\mp) < 1.6 \times 10^{-5}$.

Implementation of Machine Learning Algorithms to Form Di-Muons from Off-Shell Parent Particles

Authors: Mehdi Rahmani¹; Stephen Butalla¹

¹ *Florida Institute of Technology (US)*

Corresponding Author: mehdi.rahmani@cern.ch

In high energy physics, Machine Learning (ML) has been applied to a broad range of problems: from jet tagging to particle identification, from the separation of signal over background, to fast simulation of event data, to to name a few. In this presentation, ML algorithms and techniques are explored to form lepton pairs (di-leptons) in a dark fermionic model.

In this model, the final-state leptons are the products of off-shell dark Z (Z_D) bosons. This presents a unique challenge since the identification of their parent particle cannot be done by a simple invariant mass comparison calculation. Machine learning can greatly simplify this imposing task of matching final-state muons with their associated parent particles by exposure to correctly matched events and invalid permutations of these muons.

Monte Carlo-simulated proton-proton collision data at $\sqrt{s} = 13$ TeV, corresponding to an integrated luminosity of 35.9 fb^{-1} are preprocessed, and the resulting muon observables such as ϕ , η , p_T , and charge, as well as higher-level, calculated observables, such as the ΔR and the invariant mass of the formed dimuon pair are used as input features to ML algorithms, including XGBoost, deep neural networks, boosted decisions trees, support vector machine learning, as well as ensemble methods of the aforementioned models.

These models are trained and hyperparameter tuning is performed to achieve the highest classification accuracy. The performance of these models are compared and discussed. The methods presented here can be applied to both MC-generated and real data from the LHC, and a wide range of problems in which efficiently matching final-state particles to the decaying off-shell parent particle are necessary for proper event reconstruction.

Neutrinophilic Scalars at the LHC Forward Physics Facility

Author: Douglas Tuckler¹

¹ *Carleton University*

Corresponding Author: dtuckler@physics.carleton.ca

In a well-motivated class of beyond the Standard Model scenarios, dark matter interacts mainly with neutrinos of the SM via a neutrinophilic mediator. This scenario can leave a striking signature in neutrino detectors – the mono-neutrino signature. In this process, invisible particles (either dark matter or the mediators) can be radiated off neutrinos when they undergo charged-current weak interactions, resulting in missing transverse momentum with respect to the incoming neutrino. In this talk we discuss the possibility of probing neutrinophilic scalar mediators via the mono-neutrino signature at the proposed Forward Physics Facility (FPF) at the LHC. Because of the high energy neutrino flux produced in the forward direction of LHC detectors, the FPF will play a leading role in probing neutrinophilic scalars in a so-far unconstrained parameter space and shed light on the origin of neutrinophilic dark matter scenarios.

T2K latest results on muon neutrino and antineutrino disappearance

Author: Siva Prasad Kasetti¹

¹ *Louisiana State University (US)*

Corresponding Author: kasetti@phys.lsu.edu

T2K (Tokai to Kamioka) is a long-baseline neutrino oscillation experiment situated in Japan with a baseline of 295 km and a neutrino beam of energy peaked at 600 MeV. The experiment can record data using either a mainly neutrino or mainly anti-neutrino beam, allowing to study the difference between the oscillations of neutrinos and anti-neutrinos. In T2K, one powerful method to test the 3-flavour neutrino oscillation framework (known as PMNS formalism) is to compare the disappearance of muon neutrinos and anti-neutrinos. In order to test the compatibility, we measure the oscillation parameters describing their disappearance (θ_{23} , Δm_{32}^2) while allowing them to vary separately for neutrinos and antineutrinos. The compatibility with the PMNS framework is tested by comparing the fitted parameter values between the neutrinos and antineutrinos. For this study, we use the T2K run 1-10 data, corresponding to an exposure of 1.9664×10^{21} POT in neutrino mode and 1.6345×10^{21} POT in anti-neutrino mode.

We use the selected one ring muon candidate events in both neutrino and anti-neutrino mode to perform the joint fit which constrains the wrong-sign background. The best-fit values for Δm^2 ($\Delta \bar{m}^2$) are $2.48 \times 10^{-3} eV^2$ ($2.53 \times 10^{-3} eV^2$), and for $\sin^2 \theta_{23}$ are 0.468 (0.449). The analysis results are in agreement with the PMNS formalism.

PISCES: A hybrid parameter inference technique combining a Poisson likelihood treatment for statistical uncertainties with a Gaussian multivariate treatment for systematic uncertainties

Author: Jeremy Edmund Hewes¹

¹ *University of Cincinnati (US)*

Corresponding Author: jzhewes@gmail.com

Many particle physics experiments utilise a pull term method to perform fits to data, in which systematic uncertainties are treated as nuisance parameters that reweight the predicted spectrum. However, this approach scales poorly in fit complexity as the number of systematic uncertainties increases. Conversely, one can utilise a Gaussian multivariate technique, in which systematic uncertainties are encoded into a covariance matrix. This approach is convenient for performing joint fits, and scales well to an arbitrarily large ensemble of systematic uncertainties; however, it also treats statistical uncertainties as Gaussian, which is inappropriate in any experiment which operates in a low-statistics environment, such as a neutrino physics experiment.

We present a novel method named PISCES (Parameter Inference with Systematic Covariance and Exact Statistics), a hybrid technique that combines a Gaussian multivariate treatment of systematic uncertainties with a Poisson likelihood treatment of statistical uncertainties. Under this method, only physics nuisance parameters are profiled using a fitter, while optimal systematic pulls in each analysis bin are calculated using a covariance matrix with each evaluation of the objective function. This technique is fast and memory-efficient, and convenient for performing joint fits over many samples. Following an introduction to the method, demonstrations using toy experiments and time and memory benchmarks are presented.

Astroparticles and CMB / 404**Probing the early universe through the polarization of the Cosmic Microwave Background****Author:** RICCARDO GUALTIERI¹¹ *Argonne National Laboratory***Corresponding Author:** rgualtieri@anl.gov

In the inflationary paradigm, a background of primordial gravitational waves is predicted to be produced. These perturbations would leave a unique signature in the curl component of the cosmic microwave background (CMB) polarization (B-modes). A detection of B-modes spectrum power at degree angular scale would constrain the intensity of the tensor perturbations generated during inflation. This information is encoded in the tensor to scalar ratio r .

The B-modes power spectrum is dominated by foregrounds such as synchrotron emission and polarized dust at small angular scales and by lensed curl-free CMB polarization (E-modes) at large angular scales. To isolate the large angular scale primordial B-modes signal, small aperture telescopes such as Bicep/Keck BK must work in conjunction with Large aperture telescopes (LAT) telescopes such as the South Pole Telescope that have higher resolution and are more sensitive to smaller angular scales to be able to pristinely remove the non-primordial signals.

To date we only have upper limits on r .

Several other collaborations are measuring stringent upper limits with state of the art instruments. The combined efforts of the SPT and the BK collaboration joint analysis group, South Pole Observatory (SPO), will significantly improve the constraint ($r < 0.003$ SPO) that could come from BK data alone ($r < 0.02$ BK15). The SPO r limit will hold until the CMB-S4 results ($r < 5 \times 10^{-4}$ forecast).

Moreover, thanks to its large number of sensitive detectors, scan strategy and sky coverage on a foreground clean patch of the sky, SPT-3G will give us the capability to deliver an independent constraint on r , that will be informative on the performances of the Large Aperture Telescope design for CMB-S4.

Multi-Reactor Scientific Reach and Application Measurements with ROADSTR, a Mobile Antineutrino Detector

Author: Cristian Roca¹¹ *LLNL***Corresponding Author:** rocacatala1@llnl.gov

The aim of the Reactor Operations Antineutrino Detection Surface Testbed Rover (ROADSTR) project is to observe and monitor electron antineutrinos from nuclear reactors. ROADSTR has been designed as a readily mobile detector, allowing measurements at multiple sites using the same instrument. Besides the clear advantages towards nuclear safeguard and verification applications, an easily redeployable detector provides also a unique chance to contribute to flux and spectrum predictions for different nuclear fuels while minimizing the detector-related systematic uncertainties. Such measurements could prove crucial to understand the different anomalies spotted in the short baseline oscillation experiments, while providing benchmark measurements for different applications. In this talk, the current efforts underway within ROADSTR will be summarized, including the development of Pulse Shape Discrimination capable scintillators based in ⁶Li-doped plastic technology, the implementation of detector mobility, and the study of correlated backgrounds and their mitigation strategies.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. LLNL-ABS-823743.

Dark Energy Spectroscopic Instrument: Data Overview

Author: Julien Guy¹

¹ *Lawrence Berkeley National Lab*

Corresponding Author: jguy@lbl.gov

The Dark Energy Spectroscopic Instrument (DESI) started its main survey. Over 5 years, it will measure the spectra and redshifts of about 35 millions galaxies and quasars over 14,000 square degrees. This 3D map will be used to reconstruct the expansion history of the universe up to $z=3.5$, and measure the growth rate of structure in the redshift range 0.7-1.6 with unequaled precision. The start of the survey marks the end of a successful survey validation period during which more than one million cosmological redshifts were measured, already about as many as in any previous survey. This data set, along with many commissioning studies, has demonstrated the project meets its science requirements written many years ago. I will present how we have validated the target selection, the observation strategy and the data processing, demonstrating that we can achieve our goals in terms of density of galaxies and quasars with measured redshifts, with the required precision, for exposure times that allow us to cover one third of the sky in five years.

The T2K Near Detector Upgrade: Super Fine Grained Detector

Author: CHRISTOPHER MAUGER¹

¹ *University of Pennsylvania*

Corresponding Author: cmauger@upenn.edu

The T2K long-baseline neutrino oscillation experiment has measured a first indication of leptonic CP violation. Reducing the systematic uncertainty on predicted events at the far site is an urgent priority for the collaboration. In 2022, the T2K near detector will be upgraded to reduce systematic uncertainties to enable higher precision measurements of neutrino oscillation phenomena. The primary neutrino target of the upgraded detector is the Super Fine Grained Detector (SFGD) - a two-ton solid scintillator detector comprised of optically isolated cubes 1 cm on a side. The SFGD is flanked by high-angle time-projection chambers and time-of-flight panels that provide for full polar angle coverage of outgoing muons produced in charged current interactions. These detector systems have improved timing resolution, 3D tracking capability and the ability to measure the energy of neutrons emerging from neutrino interactions with time-of-flight techniques. In the talk, we discuss the motivation and capabilities of this new detector system as well as the current status of its design and construction.

Hints of lepton flavor non-universality in b decays

Author: Matthew Scott Rudolph¹

¹ *Syracuse University (US)*

Corresponding Author: msrudolp@syr.edu

Experimental hints of lepton flavor non-universality in the decays of b-hadrons are an exciting sign of possible new physics beyond the Standard Model. Results from multiple experiments indicate that electrons, muons, and tau leptons may not be different only because of their masses. I will review the experimental situation of these “b-anomalies”, including recent developments and prospects for the near future. Further results from LHCb, Belle II, and other experiments in the coming years should be able to confirm or rule out the presence of new physics in these decays.

Plenary Sessions / 414**Hints for flavorful new physics****Author:** Wolfgang Altmannshofer¹¹ *UC Santa Cruz***Corresponding Author:** waltmann@ucsc.edu

Flavor physics is addressing two complementary questions. First, what is the origin of the hierarchical flavor structure of the Standard Model quarks and leptons? Second, are there sources of flavor and CP violation beyond the Standard Model? I will discuss recent theoretical developments in this area, focusing mainly on the so-called “B-anomalies” – persistent hints for the violation of lepton flavor universality in decays of B mesons. I will review the status of the anomalies, discuss possible new physics explanations, and outline the prospects of resolving the anomalies with expected experimental data.

Plenary Sessions / 415**New Adventures at the LHC****Author:** Zhen Liu¹¹ *University of Minnesota***Corresponding Author:** zliuphys@umn.edu

LHC provides one of the most potent and comprehensive physics tests in the TeV realm and is on its course to realize its full potential with upgrades. Beyond the vast class of successful searches, many new and exciting opportunities are emerging. In this talk, I will highlight several new angles and directions at the LHC, such as precision physics and exotic signatures, to motivate us for the new adventures ahead.

Plenary Sessions / 416**Applying Lessons from Holography and Conformal Field Theory to Scattering****Authors:** Sabrina Gonzalez Pasterski¹; Sabrina Pasterski²¹ *Massachusetts Inst. of Technology (US)*² *MIT CMS***Corresponding Authors:** spasterski@fas.harvard.edu, sabrina.gonzalez.pasterski@cern.ch

The holographic principle tells us that quantum theories of gravity behave like lower dimensional theories without gravity. We will review lessons learned from applying this principle in the context of gauge/gravity duality and black hole thermodynamics, show how it has guided recent efforts to recast scattering amplitudes in terms of a conformal field theory living on the celestial sphere, and discuss what we might hope to gain by combining amplitudes and conformal bootstrap technology.

Plenary Sessions / 417**Recent Progress in Measuring Mixing and CP Violation in B-meson Decays****Author:** Michael David Sokoloff¹¹ *University of Cincinnati (US)***Corresponding Author:** michael.david.sokoloff@cern.ch

This talk will review the role of the CKM matrix in governing meson-antimeson oscillations and CP violation in the Standard Model. Recent measurements of B_s oscillations and decays by LHCb, CMS, and ATLAS will be discussed in this context, as will be measurements of CP violation in B_d and B_u decays. The direct measurements of the CKM angle γ (from decays produced by tree-level amplitudes) are combined and the resulting value compared to that determined indirectly.

Plenary Sessions / 418**The value of improving HEP outreach and how to participate****Author:** Don Lincoln¹¹ *Fermilab***Corresponding Author:** lincoln@fnal.gov

HEP is funded essentially entirely with public funds. Since there are many organizations that wish to receive federal funds, it is imperative that the HEP community raise its visibility among the general public. However, outreach to the public has long been neglected by the HEP community. In this talk, I will discuss the importance of outreach. I will also describe some of the methods that work, and will also mention some programs that the Snowmass process is developing to make it easier for individuals to engage in communicating with the public.

Community Session / 419**What Is The "DELTA-PHY" initiative?**

Many have observed for organizations there is evidence to support the belief that their cultures are their destinies. During the summer of 2020, the DELTA-PHY initiative was launched in an effort for the APS to deliberate upon and if needed move to transform its culture. It does this by asking three key questions: (a.) What are the values of the APS? (b.) Aside from producing world-class physics, what are the inputs, outputs, practices, traditions of the APS? (c.) Do answers to these questions align and are they in alignment with the APS 2019 strategic plan? DELTA PHY activities are envisioned to be timely and cutting across the society's 'stove pipe' structures.

(g-2)_μ from lattice QCD and experiments: 4.2 sigma, indeed?

Twenty years ago, in an experiment at Brookhaven National Laboratory, physicists detected what seemed to be a discrepancy between measurements of the muon's magnetic moment and theoretical calculations of what that measurement should be, raising the tantalizing possibility of physical particles or forces as yet undiscovered. The Fermilab team has just announced that their precise measurement supports this possibility. The reported significance for new physics is 4.2 sigma just slightly below the discovery level of 5 sigma. However, an extensive new calculation of the muon's

magnetic moment using lattice QCD by the BMW-collaboration reduces the gap between theory and experimental measurements. The lattice result appeared in Nature on the day of the Fermilab announcement. In this talk both the theoretical and experimental aspects are summarized with two possible narratives: a) almost discovery or b) Standard Model re-inforced. Some details of the lattice calculation are also shown.

Cosmological Constraints from the Dark Energy Survey Year 3

Author: Felipe Andrade-Oliveira¹

¹ *IFT UNESP/LineA*

Corresponding Author: felipeaoli@gmail.com

The Dark Energy Survey has observed large scale structure data in 5000 sq. deg in sky. This effort was done in collaboration with hundreds of scientists culminating in the more accurate and precise constraints to date on the cosmology of the late-time Universe.

In this talk, I discuss the methodology and measurements in the third year of the Dark Energy Survey. I review the results from the Cosmological analysis and, finally, I discuss the tension of Large Scale Structure constraints from DES and the Planck experiment and the efforts that are already being developed for the next generation of DES data.

DUNE and LBL Neutrino Program

Author: Jose Maneira¹

¹ *LIP-Lisboa*

Corresponding Authors: jose.maneira@cern.ch, maneira@lip.pt

The Deep Underground Neutrino Experiment (DUNE) is a next-generation long-baseline neutrino experiment. Its main physics goals are the precise measurement of the neutrino oscillation parameters, in particular the violation of the charge-parity symmetry and the neutrino mass hierarchy. DUNE consists of a Far Detector (FD) complex with four multi-kiloton liquid argon detectors, and a Near Detector (ND) complex located close to the neutrino source at Fermilab (USA). Here we present an overview of the DUNE experiment, its detectors, and physics capabilities, within the context of the long baseline program of the next decade.

AI in HEP: Current Methods and Applications

Author: Savannah Jennifer Thais¹

¹ *Princeton University (US)*

Corresponding Author: savannah.jennifer.thais@cern.ch

In recent years, Machine Learning (ML) and Artificial Intelligence (AI) methods have become ubiquitous in High Energy Physics research. Though initial implementations of ML for HEP focused mainly on supervised learning for classification problems like jet tagging or event selection, HEP researchers are increasingly employing cutting edge techniques for a wide range of applications and even contributing to advances in the field of ML and AI. This talk will describe current ML methods being studied for a range of HEP use cases including data collection, reconstruction, tagging, simulation, and inference; methods discussed will include geometric machine learning, deep learning, unsupervised and weakly supervised models, and more.

Status of the ATLAS ITk Strip Detector

Author: Karol Krizka¹

¹ *Lawrence Berkeley National Lab. (US)*

Corresponding Author: karol.krizka@cern.ch

ATLAS is preparing for the HL-LHC upgrade, where integrated and instantaneous luminosity will reach unprecedented values. For this, an all-silicon Inner Tracker (ITk) is under development with a pixel detector surrounded by a strip detector. The strip system consists of 4 barrel layers and 6 endcap disks. Prototyping has been completed successfully, and pre-production is about to start. We present an overview of the Strip System, highlighting the deliverables from the US. We will outline the current status of pre-production on various detector components, with an emphasis on QA and QC procedures. We will also discuss the plans for the pre-production and production phase distributed over many institutes.

Beyond Standard Model / 442**Search for electroweak production of charginos and neutralinos in final states with two boosted hadronically decaying bosons and missing transverse momentum in pp collisions at $\sqrt{s}=13$ TeV with the ATLAS detector****Author:** Joseph Mullin¹¹ *University of Pennsylvania (US)***Corresponding Author:** joseph.james.mullin@cern.ch

A search for electroweak production of charginos and neutralinos at the Large Hadron Collider was conducted in 139 fb^{-1} of proton-proton collision data collected at a center of mass energy of $\sqrt{s} = 13$ TeV with the ATLAS detector. This search utilizes fully hadronic final states with missing transverse momentum to identify signal events with a pair of charginos or neutralinos that subsequently decay into high- p_T gauge or Higgs bosons as well as a lighter chargino or neutralino. The light chargino or neutralino creates missing transverse momentum and each of the bosons can decay to light- or heavy-flavor quark pairs. Fully hadronic final states have a large branching ratio compared to leptonic or semi-leptonic decays, probing high-mass signals which have a smaller production cross-section, giving strong motivation to explore this final state. The inclusion of more signal leads to more background, by exploiting boosted boson tagging techniques the additional background can be suppressed. This boson tagging is achieved by reconstructing and identifying the high- p_T SM bosons using large-radius jets and their substructure. No significant excess is found beyond standard model expectations. Various assumptions in decay branching ratios and the type of LSP were made to set exclusion limits on wino or higgsino production at a 95% confidence level. These excluded a mass of 1050 and 900 GeV for the wino and higgsino respectively when the lightest SUSY particle has a mass below 400 and 250 GeV.

Are you are a member of the APS Division of Particles and Fields?:**Beyond Standard Model / 443****Search for Low Mass Dark Photons in the CMS Hadronic Calorimeter (HCAL) in Proton-Proton Collisions at $\sqrt{s} = 13$ TeV****Authors:** Devin Nathaniel Taylor¹; Mani Tripathi¹; Yao Yao¹; Mani Tripathi²¹ *University of California Davis (US)*² *UC Davis***Corresponding Author:** alexisyao@gmail.com

We present a search for a low mass dark photon below 1 MeV which is radiated from a muon in proton-proton collisions at a center-of-mass energy of 13 TeV. A low mass dark photon has no available decay channel to standard model particles, and is hence stable. We assume that a dark photon directly interacts with detector materials through bremsstrahlung, and its small kinetic mixing, in which the dark photon converts to and from the normal photon, means depositing energy outside the CMS Electromagnetic Calorimeter. The search is model-independent, and applies to all dark photons with mass lower than 1 MeV. I will present preliminary feasibility studies using Monte Carlo simulation, which have shown that a dark photon shower in HCAL is distinguishable from the standard model backgrounds.

Upgrade of the ATLAS Monitored Drift Tube Frontend Electronics for the HL-LHC

Authors: Zhichen Wang¹; Zhichen Wang²

¹ *University of Michigan*

² *University of Michigan (US)*

Corresponding Authors: zhichenw@umich.edu, zhichen.wang@cern.ch

The monitored drift tube (MDT) chambers are the main component of the precision tracking system in the ATLAS muon spectrometer, capable of measuring the sagitta of muon tracks to an accuracy of 60 μm , which corresponds to a momentum accuracy of about 10% at $p_T=1$ TeV. To cope with large amount of data and high event rate at HL-LHC, the present MDT readout electronics will be replaced and the MDT detector will be used at the first-level trigger with an output event rate of 1 MHz and a latency of ~ 6 us. Prototypes for two frontend ASICs, a frontend mezzanine card and a data transmission board have been realized and tested. The design of a mobile mini-Data Acquisition system is ongoing and will be crucial for testing newly-built small-diameter MDT chambers with new frontend electronics prototypes and for future integration and commissioning. I will present the overall design of MDT frontend electronic system, results from ASIC and board prototypes and tests using the miniDAQ system.
