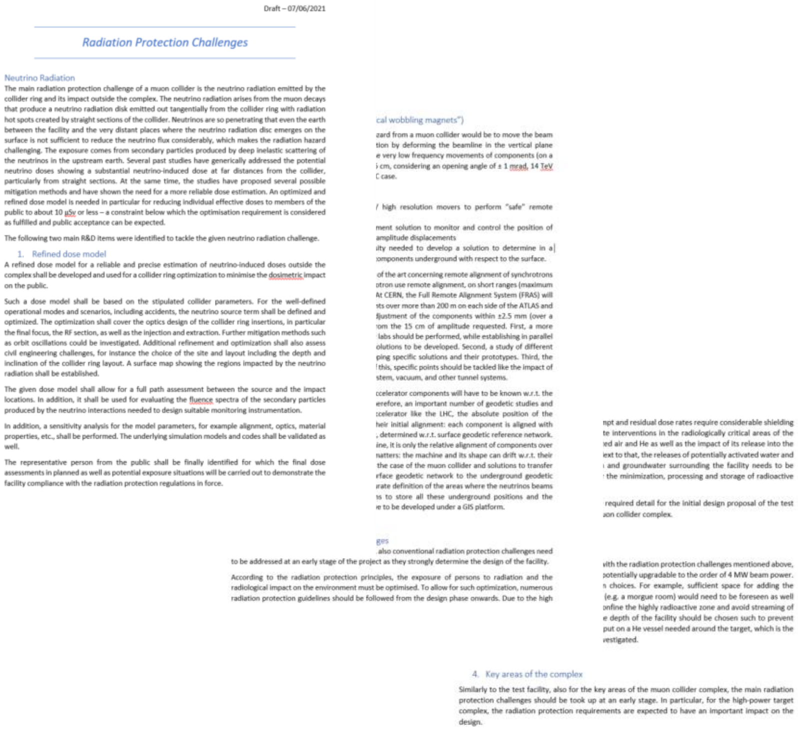
2nd Muon Community Meeting

13 July 2021

List of challenges identified by RP WG

- Neutrino Radiation
  1. Refined dose model
  2. Mitigation by movers ("mechanical wobbling magnets")
- Additional Radiation Protection challenges
  3. Test facility
  4. Key areas of the complex



Draft – 07/06/2021

Radiation Protection Challenges

Neutrino Radiation

The main radiation protection challenge of a muon collider is the neutrino radiation emitted by the collider ring and its impact outside the complex. The neutrino radiation arises from the muon decays that produce a neutrino radiation disk emitted out tangentially from the collider ring with radiation hot spots created by straight sections of the collider. Neutrinos are so penetrating that even the earth between the facility and the very distant places where the neutrino radiation disc emerges on the surface is not sufficient to reduce the neutrino flux considerably, which makes the radiation hazard challenging. The exposure comes from secondary particles produced by deep inelastic scattering of the neutrinos in the upstream earth. Several past studies have generically addressed the potential neutrino doses showing a substantial neutrino-induced dose at far distances from the collider, particularly from straight sections. At the same time, the studies have proposed several possible mitigation methods and have shown the need for a more reliable dose estimation. An optimized and refined dose model is needed in particular for reducing individual effective doses to members of the public to about 10 µSv or less – a constraint below which the optimisation requirement is considered as fulfilled and public acceptance can be expected.

The following two main R&D items were identified to tackle the given neutrino radiation challenge.

1. Refined dose model

A refined dose model for a reliable and precise estimation of neutrino-induced doses outside the complex shall be developed and used for a collider ring optimization to minimise the dosimetric impact on the public.

Such a dose model shall be based on the stipulated collider parameters. For the well-defined operational modes and scenarios, including accidents, the neutrino source term shall be defined and optimized. The optimization shall cover the optics design of the collider ring insertions, in particular the final focus, the RF section, as well as the injection and extraction. Further mitigation methods such as orbit oscillations could be investigated. Additional refinement and optimization shall also assess civil engineering challenges, for instance the choice of the site and layout including the depth and inclination of the collider ring layout. A surface map showing the regions impacted by the neutrino radiation shall be established.

The given dose model shall allow for a full path assessment between the source and the impact locations. In addition, it shall be used for evaluating the fluence spectra of the secondary particles produced by the neutrino interactions needed to design suitable monitoring instrumentation.

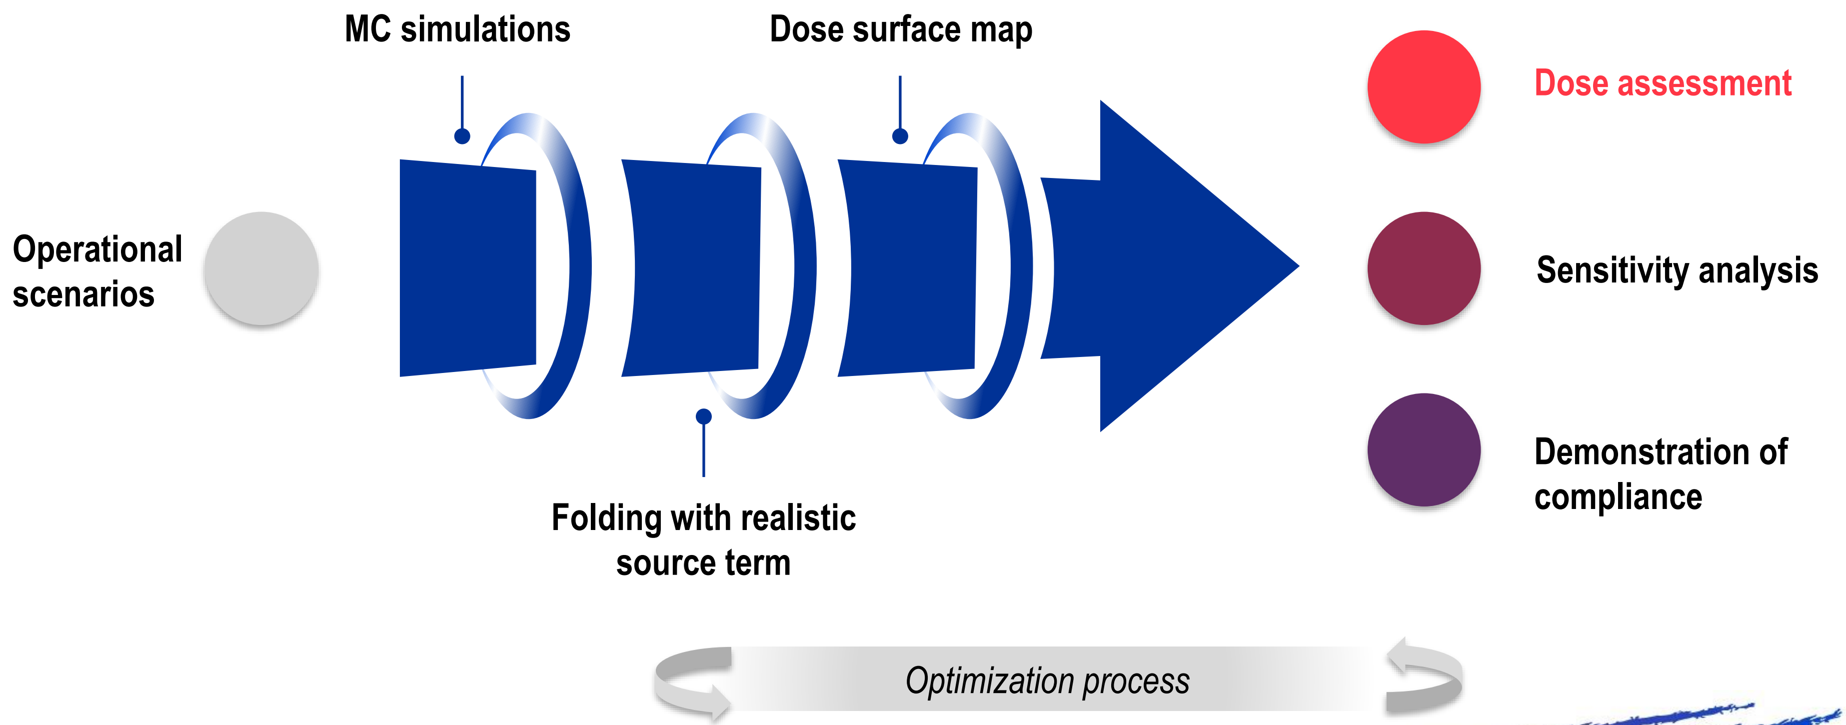
In addition, a sensitivity analysis for the model parameters, for example alignment, optics, material properties, etc., shall be performed. The underlying simulation models and codes shall be validated as well.

The representative person from the public shall be finally identified for which the final dose assessments in planned as well as potential exposure situations will be carried out to demonstrate the facility compliance with the radiation protection regulations in force.

4. Key areas of the complex

Similarly to the test facility, also for the key areas of the muon collider complex, the main radiation protection challenges should be took up at an early stage. In particular, for the high-power target complex, the radiation protection requirements are expected to have an important impact on the design.

Overview of work related to a refined dose model



Operational scenarios

- Dose model shall be based on the stipulated collider parameters

Tentative target parameters

Defined by the Muon Beam Panel

Target integrated luminosities

$\sqrt{s}$	$\int \mathcal{L}dt$
3 TeV	$1\ \mathrm{ab}^{-1}$
10 TeV	$10\ \mathrm{ab}^{-1}$
14 TeV	$20\ \mathrm{ab}^{-1}$

Reasonably conservative

- each point in 5 years with tentative target parameters
- FCC-hh to operate for 25 years
- Aim to have two detectors
- But might need some operational margins

Note: focus on 3 and 10 TeV
Have to define staging strategy

Tentative target parameters
Scaled from MAP parameters

Comparison:
CLIC at 3 TeV: 28 MW

Parameter	Unit	3 TeV	10 TeV	14 TeV
L	$10^{34}\ \mathrm{cm^{-2}s^{-1}}$	1.8	20	40
N	10^{12}	2.2	1.8	1.8
f_r	Hz	5	5	5
P_{beam}	MW	5.3	14.4	20
C	km	4.5	10	14
<B>	T	7	10.5	10.5
ε_L	MeV m	7.5	7.5	7.5
σ_E / E	%	0.1	0.1	0.1
σ_z	mm	5	1.5	1.07
β	mm	5	1.5	1.07
ε	µm	25	25	25
$\sigma_{x,y}$	µm	3.0	0.9	0.63

D. Schulte Muon Collider, March 23, 2021 14

- A dose model will be defined for each parameter set
- Prioritization (?):
  - 3 TeV
  - 10 TeV
  - 14 TeV

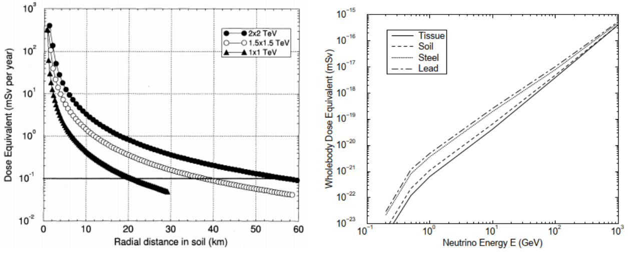
Past Monte Carlo simulations

- **Comprehensive MARS15** simulations with a sophisticated neutrino interaction model crucial for evaluation of induced dose and secondary particle for monitoring
  → Mokhov and Ginneken, Neutrino Radiation at Muon Colliders and Storage Rings, 2000
- Studies for E_{com} 0.5, 1, 3, and 4 TeV muon colliders:
  - Effective dose for broad and pencil neutrino beams
  - Secondary particle equilibrium and non-equilibrium cases
  - Maximum and whole-body values for variety materials upstream the tissue-equivalent phantom
  - Contributions from both the collider ring and field free drifts
  - Standalone case of monoenergetic neutrino beams of energies from 100 MeV to 10 TeV
  - Idea of vertical wobbling of muon beams in the ring was introduced and calculated showing substantial effect of dose reduction
- Good agreement with **FLUKA simulations**
  → Bartosik et al., Preliminary Report on the Study of Beam-Induced Background Effects at a Muon Collider, 2019

→ **To be built on for additional MC studies**

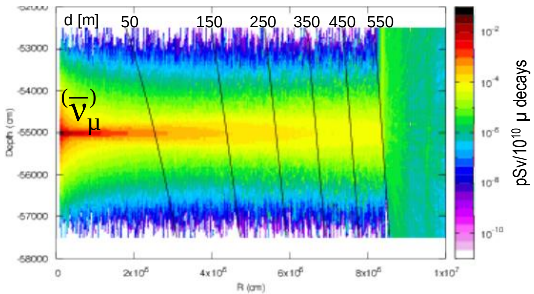
Few examples

MARS15 dose eq. vs. distance + E_ν for diff. materials



Mokhov and Ginneken, Neutrino Radiation at Muon Colliders and Storage Rings, 2000

FLUKA H*(10) for 2 TeV vs. distance + depth



Bartosik et al., Preliminary Report on the Study of Beam-Induced Background Effects at a Muon Collider, 2019

Plans for Monte Carlo simulations

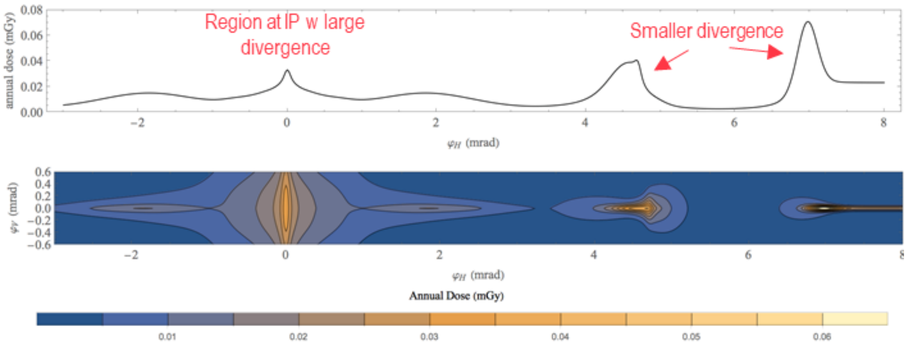
- Simplified FLUKA and MARS simulations with a **pencil neutrino beam** for the given operational scenarios (E_{com} 3, 10, 14 TeV (tbc)) to evaluate main parameters for the dose predictions, such as:
  - **Dose distribution** for different distances (collider depths) assuming secondary particle equilibrium (i.e. inside material) → Folding w realistic source term
  - **Sensitivity studies** for underlying assumptions (e.g. material properties, nu_e/mu and antineutrino)
  - **Differences** of possibly relevant **dosimetric quantities** (e.g. effective dose, ambient dose equivalent, eff. dose equivalent)
  - Difference to a more realistic **full path assessment**

  → Sensitivity analysis (for the three items above)
  - **Secondary particle spectra** needed to design suitable monitoring instrumentation → Demonstration of compliance
- Benchmarking of **neutrino interaction models** → Sensitivity analysis

Folding with a realistic source term

- Evaluate **dose distributions** for a **realistic neutrino source term** taking into account:
  - The **real lattice** (collider, injection, accelerators)
  - The angular distribution from the **muon decay**
- Fold the information from MC simulations to estimate the dose distributions
  → more precise and less conservative dose estimation than analytical approach taking additional spread of secondary particle distribution into account
- **Identification** of **critical regions** (high dose areas)
- **Optimization** of the **source term** (e.g. lattice, wobbling) with respect to the dose
- **Sensitivity study** of underlying assumptions (e.g. closed orbit positions)

Example of using analytical approach for region around IP



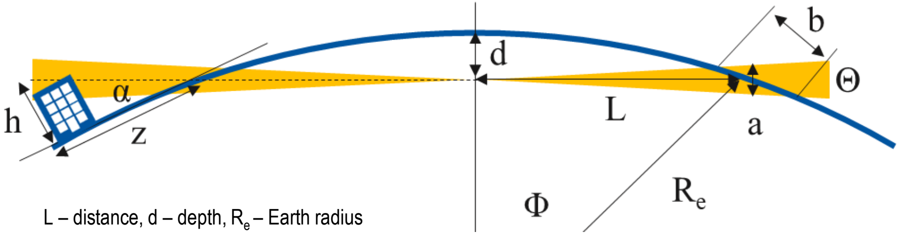
C. Carli, Considerations on Radiation, Muon Collider Design Meeting, 08.03.2021
(3 TeV, 100 m depth, analytical approach based on B. King)

Dose surface map

Sensitivity analysis

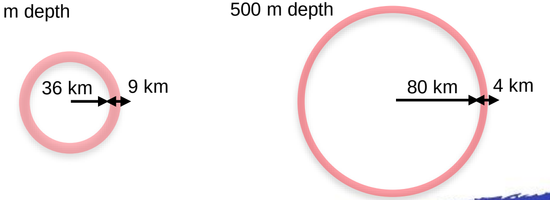
Dose surface map

- Establish **surface map of dose**
- **Optimization** w.r.t. depth, orientation and inclination
- Investigation of different **site options**
- Evaluation of **uncertainties** of methodology (e.g. accuracy of terrain model) ➤ Sensitivity analysis
- Preliminary study of where ν break ground for LHC/SPS straight sections (see presentation Y. Robert)
- Findings from simplified geometrical considerations (Earth as perfect sphere, no divergence, no collider inclination) for ν beam:
  - ν disk has a height (a) of ~1.1-2.5 m and traverses a region of width (b) of ~100-450 m
  - For dose additional spread of few m due to sec. particle shower
  - Exit angle of ν radiation is very small, wherefore **impacted area** can be of **several km** depending on height considered



L – distance, d – depth, R_e – Earth radius

E_{com} [TeV]	3	10	10	14	14
d (m)	100	200	300	400	500
L (km)	36	51	62	71	80
a (m)	2.5	1.1	1.3	1.1	1.2
b (m)	449	135	135	96	96



$L^2 = R_e^2 - (R_e - d)^2$
$\Theta \sim 1/\gamma$
$a \approx 2\,\Theta L$
$b \approx a/\Phi$, $\sin\Phi = L/R_e$

See also paper from Johnson, Rolandi and Silari, Radiological Hazard Due to Neutrinos from a Muon Collider, 1998

Dose assessment

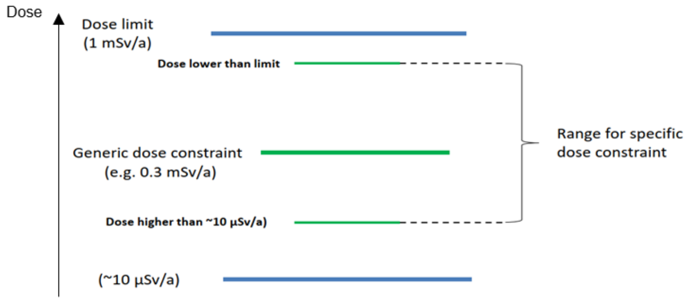
- Identify representative person from public for a final dose assessment
- As a general worst case scenario, one would have to assume maximum exposure and irradiation conditions (e.g. sick person lying in bed 24/7 at the location of the maximum dose)

  → Dose optimization to O(10) μSv/year
- Depending on the dose surface map, for certain regions of higher dose (e.g. for critical straight sections), possible exclusion of such a worst case scenario even for the far future

  → Dose higher than O(10) μSv/year depending on possible exposure scenarios (e.g. lake, mountains, ocean, exclusion area)

  – Depends on acceptance by authorities and public
  – Uncertainty of the dose surface map → Sensitivity analysis

ICRP and IAEA Safety standards –
Relationship between dose limit, generic and specific dose constraint, and optimization level

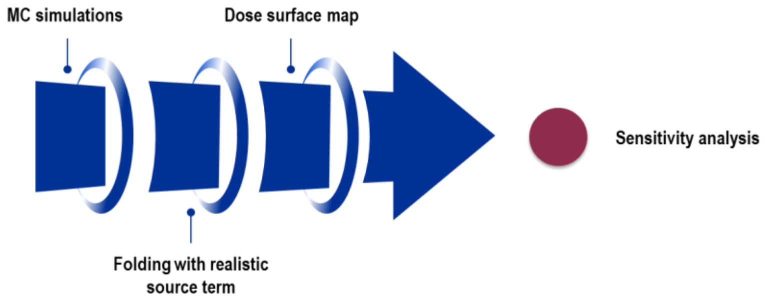


IAEA Safety Standards, General Safety Guide, No. GSG-9

100 rem = 1Sv

Sensitivity analysis and demonstration of compliance

Sensitivity analysis



- Uncertainties of dose estimate to be defined based on the various underlying parameters and assumptions
- This includes uncertainties for the dose distribution as well as its projection on the surface

Demonstration of compliance

- Evaluate means to demonstrate compliance of the dose estimates, both at the source (emission) and impact side (immission)

Source side

- Measure muon beam parameters (e.g. divergence)

Impact side

- Design suitable monitoring instrumentation for measuring the dose from the secondary particles produced by the neutrino radiation

Proposed Workpackage Description

Neutrino radiation

1. **Refined dose model**
   A refined dose model for a reliable and precise estimation of neutrino-induced doses outside the complex shall be developed and used for a collider ring optimization to minimise the dosimetric impact on the public
2. **Mitigation by movers**
   Mitigation by movers, which move the beam line components to change the beam direction by deforming the beamline in the vertical plane

Additional RP challenges

3. **Test facility**
   The test facility design will have to be optimised w.r.t. prompt and residual radiation, air/He/N activation, water and soil activation, and radioactive waste production, particularly when aiming at potentially upgrading to O(4) MW beam power
4. **Key areas of the complex**
   Similarly to the test facility, also for the key areas of the muon collider complex, the main RP challenges should be investigated at an early design stage

Proposed Workpackage Tasks and Timeline – Refinded Dose Model

Preliminary – Timeline tbd

- **MC simulations**
  - MC simulations (FLUKA, MARS) to evaluate main parameters for the dose predictions and their uncertainties [202X-202X]
  - Benchmarking of neutrino production and interaction models [202X-202X]
- **Folding with realistic source term**
  - Evaluation of a realistic neutrino source term and folding with dose distributions from MC simulations [202X-202X]
  - Further optimization and sensitivity analysis [202X-202X]
- **Surface map**
  - Surface map of the dose for given site options [202X-202X]
  - Further optimization and sensitivity analysis [202X-202X]
- **Dose assessment + demonstration of compliance**
  - Perform final dose assessment and develop possible methods to demonstrate compliance [202X-202X]

Information Needed For Workpackage

- Specific collider parameters (E, circumference) are needed as input for the refined dose model [ASAP]
- *Other?*

Proposed Workpackage Tasks and Timeline – Mitigation Using Movers

International MUON Collider Collaboration

Very preliminary work plan

International MUON Collider Collaboration

- *K1: Development of large stroke/high resolution movers*
  - Study of SOTA / establishment of requirements (tech. Student) [ASAP]
  - Study of different options, concepts, up to the engineering (PhD student) [2022-2024]
  - Qualification of prototypes (tech student) [2025]
- *K2: Development of remote solutions to control the position of components*
  - Study of solutions + concepts of alignment sensors (PhD student) [2022-2024]
  - Development of first options / solutions / qualification of prototypes (fellow) [2024-2026]
- *K3: Accuracy of absolute position needed (underground vs surface)*
  - Some synergies with Geodetic studies undertaken for FCC
  - Adapt them to the specific case of muon collider: simulations (Post-doc) or development of specific methods (PhD student)

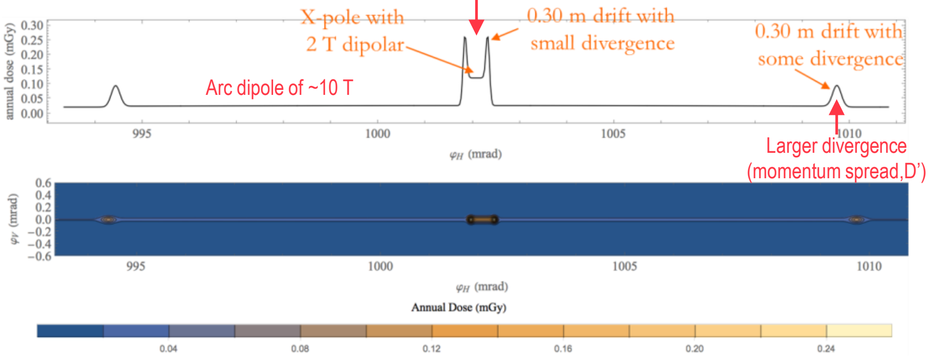
Dose estimation with MAP lattice – C. Carli

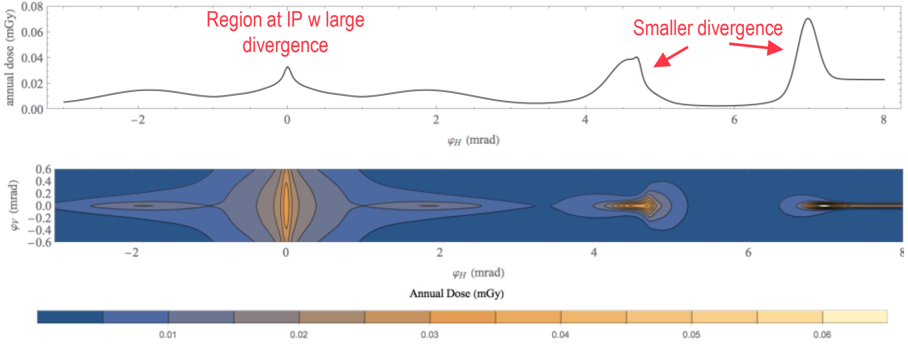
International MUON Collider Collaboration

CERN

Center of arc cell



Region around IP



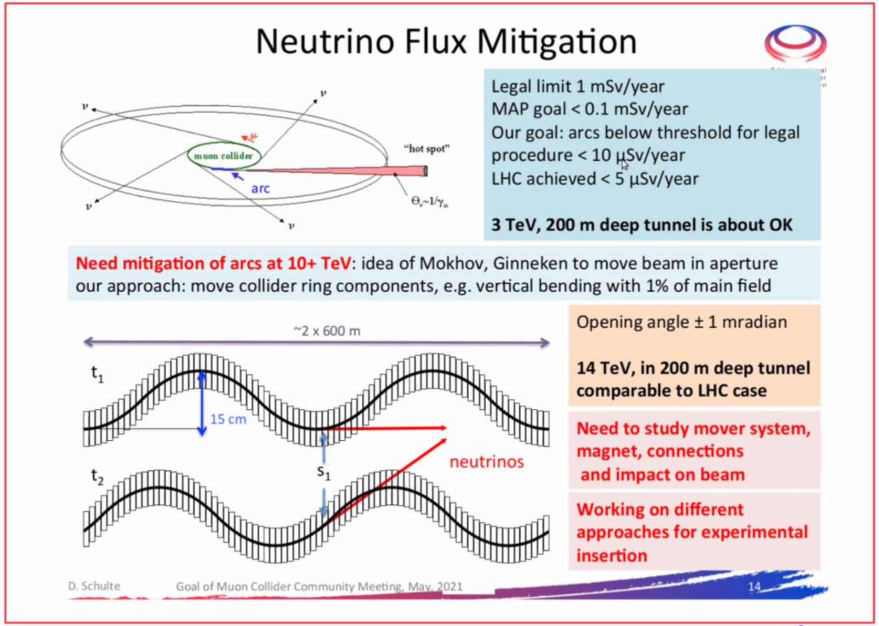
According to paper of B. King Gy!=Sv

- Based on analytical approach by B. King
- Application to 3 TeV c.o.m. lattice from MAP study (9e20 μ decays per year, depth = 100)
- Findings from the arcs: higher doses for reduced field sections and peak doses for small (30 cm) drift sections
- Findings close to IP: beam divergence relatively large at IP and higher dose from regions with smaller vertical/horizontal divergence

- Conclusions:
  - Beam divergence not always negligible (contributions from D' w large momentum spread), which mitigates radiation from straight sections → avoid combined function magnets w too low dipolar field components
- Outlook:
  - Improve lattice designs in arcs (e.g. avoid short straight sections w D'=0, increase dipolar component of combined function magnets)

Mitigation using movers – H. Mainaud Durand

- Mitigation studies on the so-called neutrino radiation:
  - One possibility would be to move the beam line components to change the beam direction (by deforming the beamline in the vertical plane).
  - Very low frequency movements of components within 15 cm.



- Brief overview of state of the art including Full Remote Alignment System (FRAS): ± 5 mm

Mitigation using movers – H. Mainaud Durand

Studies to undertake / points to check (only subset given here)

- Study in further details the state of the art concerning adjustment solutions
- Have a better understanding of the requirements
  - Range of movers ? Resolution? Accuracy?
  - Long-term stability, impact of vibrations?
  - Frequency of adjustment?
  - Constraints from other equipment like cryo and vacuum (acting forces, flexibility)?
  - Weight, size and number of components?
- Study and develop alignment solutions and associated sensors for allowing to do such remote adjustment

Identified key issues

K1. Development of large stroke/high resolution movers to perform safe remote displacements

K2. Development of remote solutions to control the position of components (for circular collider), adapted to such ranges of displacements

K3. Study of the accuracy needed / necessity to develop a solution to determine in a continuous way the absolute position of components underground vs. surface

+ specific points to address (impact on other equipment, safe control system)
