Inclusive neutrino-nucleus cross sections at intermediate energy transfers: *Valencia* model

(cross sections vs systematics)

J. Nieves

IFIC (CSIC & UV)

UNIVERSITAT
ID VALÈNCIA

Theoretical (many body) approach

$$\frac{d^2\sigma}{d\Omega(\hat{k}')dE'} = \frac{|\vec{k}'|}{|\vec{k}|} \frac{G^2}{4\pi^2} L_{\mu\sigma} W^{\mu\sigma}$$

For instance, charged current process

$$L_{\mu\sigma} = k'_\mu k_\sigma + k'_\sigma k_\mu - g_{\mu\sigma} k \cdot k' + i\epsilon_{\mu\sigma\alpha\beta} k'^\alpha k^\beta$$

$$W^{\mu\sigma} = W_s^{\mu\sigma} + iW_a^{\mu\sigma}$$

$$W_s^{\mu\sigma} \propto \int \frac{d^3r}{2\pi} \text{Im} \left\{ \Pi_W^{\mu\sigma}(q, \rho) + \Pi_W^{\sigma\mu}(q, \rho) \right\} \Theta(q^0)$$

$$W_a^{\mu\sigma} \propto \int \frac{d^3r}{2\pi} \text{Re} \left\{ \Pi_W^{\mu\sigma}(q, \rho) - \Pi_W^{\sigma\mu}(q, \rho) \right\} \Theta(q^0)$$

Basic object $\Pi_{W,Z^0,\gamma}^{\nu\rho}(q, \rho)$ \equiv Selfenergy of the Gauge Boson (W^\pm, Z^0, γ) inside of the nuclear medium. Perform a Many Body expansion, where the relevant gauge boson absorption modes should be systematically incorporated: absorption by one N, or NN or even 3N, real and virtual (MEC) meson (π, ρ, \dots) production, Δ excitation, etc...

$W^+ n \rightarrow p$

$W^+ N \rightarrow \Delta, N^*$

$W^+ NN \rightarrow NN$
 $W^+ N \rightarrow N \pi, N\rho, \dots$

$$p^2 \approx (p + q)^2$$

$$2pq + q^2 \approx 0$$

$$q^0 \approx -\frac{q^2}{2M} = \frac{|\vec{q}|^2 - (q^0)^2}{2M}$$

QE (1p1h) contribution

first ingredient $W^\pm NN'$ (or $Z^0 NN$ or $\gamma^* NN$) in vacuum, after nuclear corrections should be included.....

$$\sum_{n < F} \left| \begin{array}{c} p \\ \text{---} W^+ \text{---} \\ n \end{array} \right|^2$$

Spectral Functions (SRC) populate neither the **dip** nor the Δ regions

- **Spectral Function (SF) + Final State Interaction (FSI):** dressing up the nucleon propagator of the hole (SF) and particle (FSI) states in the ph excitation

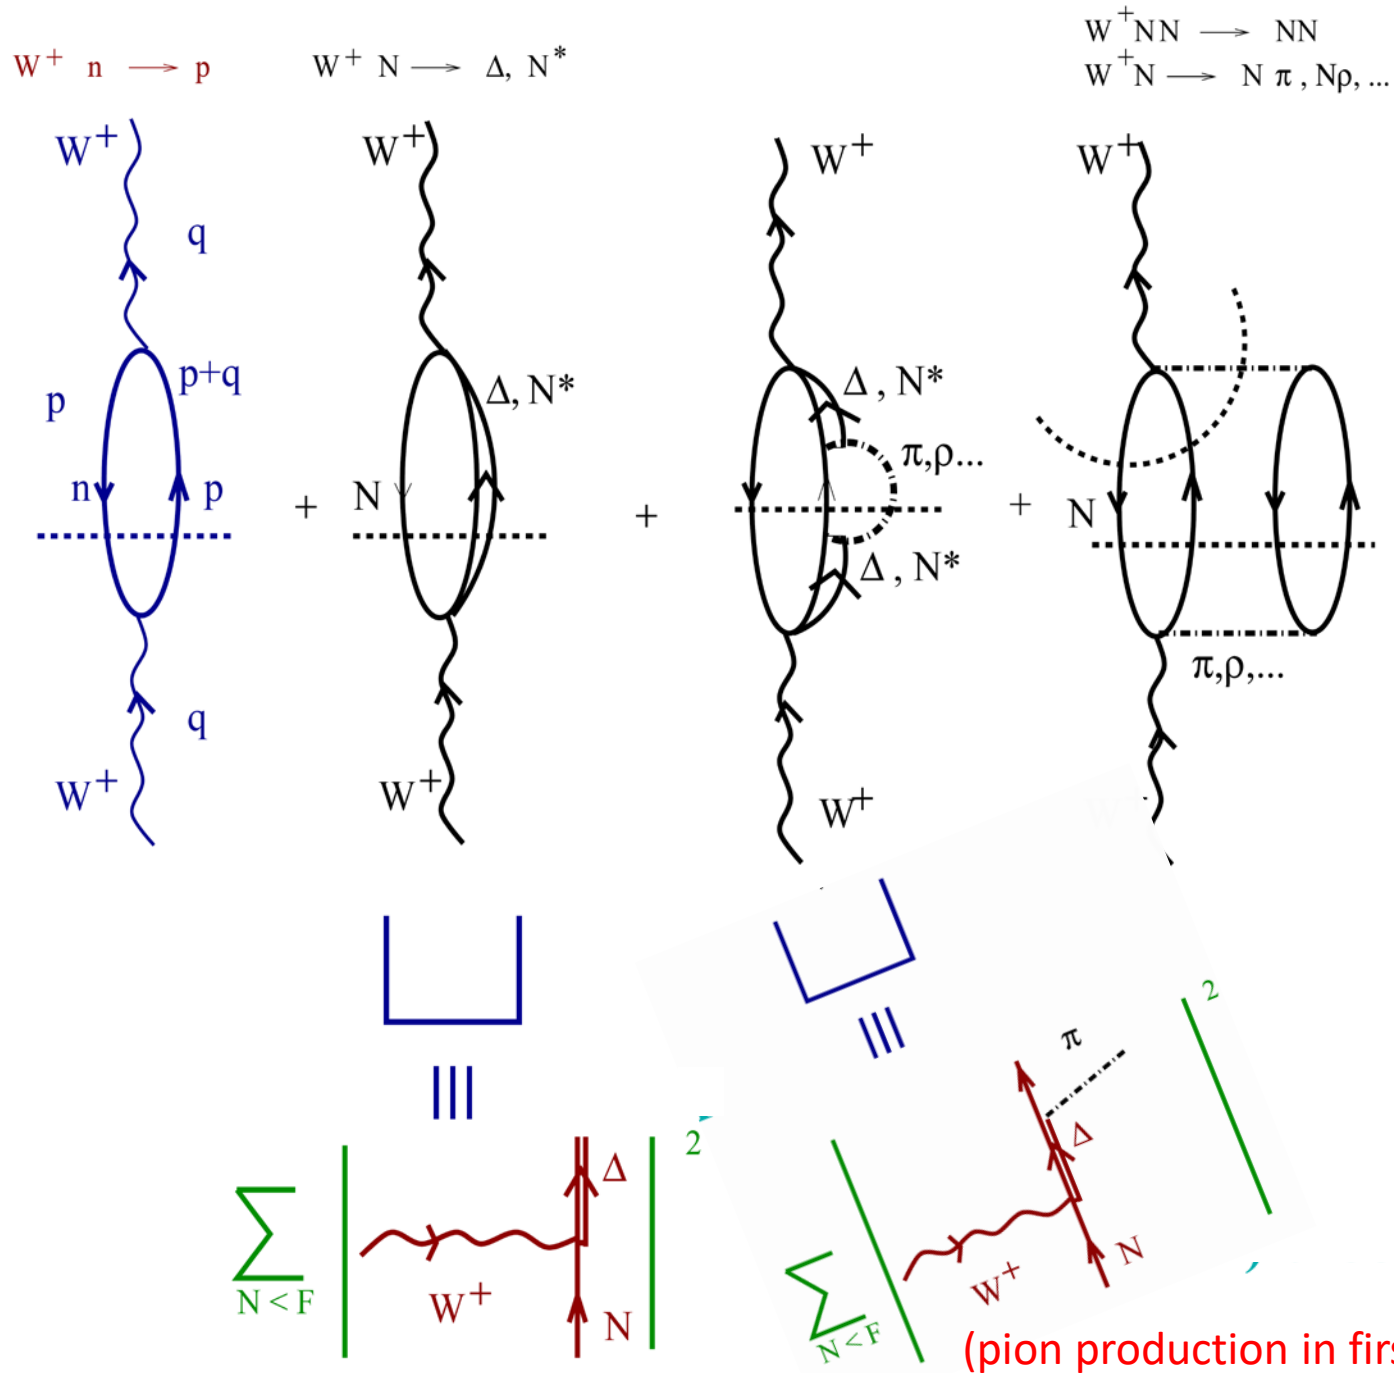

- Change of nucleon dispersion relation:
 - * hole \Rightarrow Interacting Fermi sea (SF)
 - * particle \Rightarrow Interaction of the ejected nucleon with the final nuclear state (FSI)

$$G(p) \rightarrow \int_{-\infty}^{\mu} d\omega \frac{S_h(\omega, \vec{p})}{p^0 - \omega - i\epsilon} + \int_{\mu}^{+\infty} d\omega \frac{S_p(\omega, \vec{p})}{p^0 - \omega + i\epsilon}$$

The hole and particle spectral functions are related to nucleon self-energy Σ in the medium,

$$G(p) = \frac{n(\vec{p})}{p^0 - \epsilon(\vec{p}) - i\epsilon} + \frac{1 - n(\vec{p})}{p^0 - \epsilon(\vec{p}) + i\epsilon}$$

Excitation of $\Delta(1232)$ degrees of freedom, $T = 3/2$ and $J^P = 3/2^+$

- energy transfer should be sufficiently large...
- because of the large $\pi N \Delta$ coupling, the properties of pion inside of a nuclear medium become important

INCLUSIVE CROSS SECTION

PRC 83 (2011) 045501 [$M_A = 1.049$ GeV]

MICROSCOPIC MODEL: PREDICTIONS (NO FITTED PARAMETERS) FROM THE QE TO the Δ PEAKS, INCLUDING THE DIP REGION

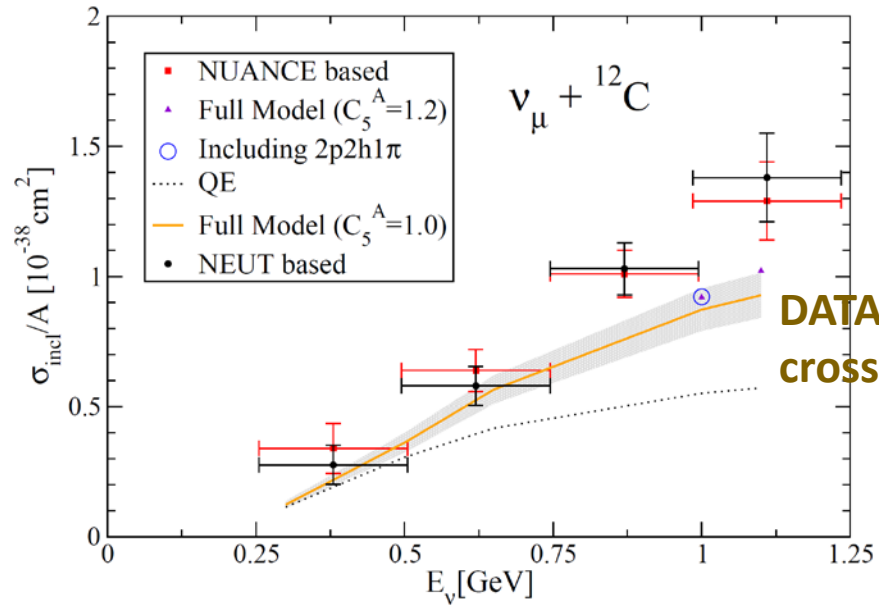

O. Benhar@NuFacT11: [arXiv : 1110.1835] measured electron-carbon scattering cross sections for a fixed outgoing electron angle $\theta = 37^\circ$ and different beam energies $\in [730, 1501]$ GeV, plotted as a function of E_e ,

A CONSISTENT MICROSCOPIC DESCRIPTION of the QE, DIP and Δ , REGIONS BECOMES FUNDAMENTAL BECAUSE THE NEUTRINO BEAM IS NOT MONOCHROMATIC

The energy bin corresponding to **the top of the QE peak at $E_e = 730$ MeV** receives significant contributions from cross sections corresponding to different beam energies and **different mechanisms!**

MiniBooNE CCQE-like double differential cross section $\frac{d^2\sigma}{dT_\mu d\cos\theta_\mu}$

We define a **merit function** and consider our **QE+2p2h** results

$$\chi^2 = \sum_{i=1}^{137} \left[\frac{\lambda \left(\frac{d^2\sigma^{exp}}{dT_\mu d\cos\theta} \right)_i - \left(\frac{d^2\sigma^{th}}{dT_\mu d\cos\theta} \right)_i}{\lambda \Delta \left(\frac{d^2\sigma}{dT_\mu d\cos\theta} \right)_i} \right]^2 + \left(\frac{\lambda - 1}{\Delta\lambda} \right)^2,$$

that takes into account the **global normalization uncertainty** ($\Delta\lambda = 0.107$) claimed by the MiniBooNE collaboration.

We fit λ to data with a fixed value of M_A ($=1.049$ GeV).

We obtain $\chi^2/\#$ bins $=52/137$ with $\lambda = 0.89 \pm 0.01$.

The microscopical model, with no free parameters, agrees remarkably well with data! The shape is very good and χ^2 strongly depends on λ , which is strongly correlated with M_A .

QE-like!

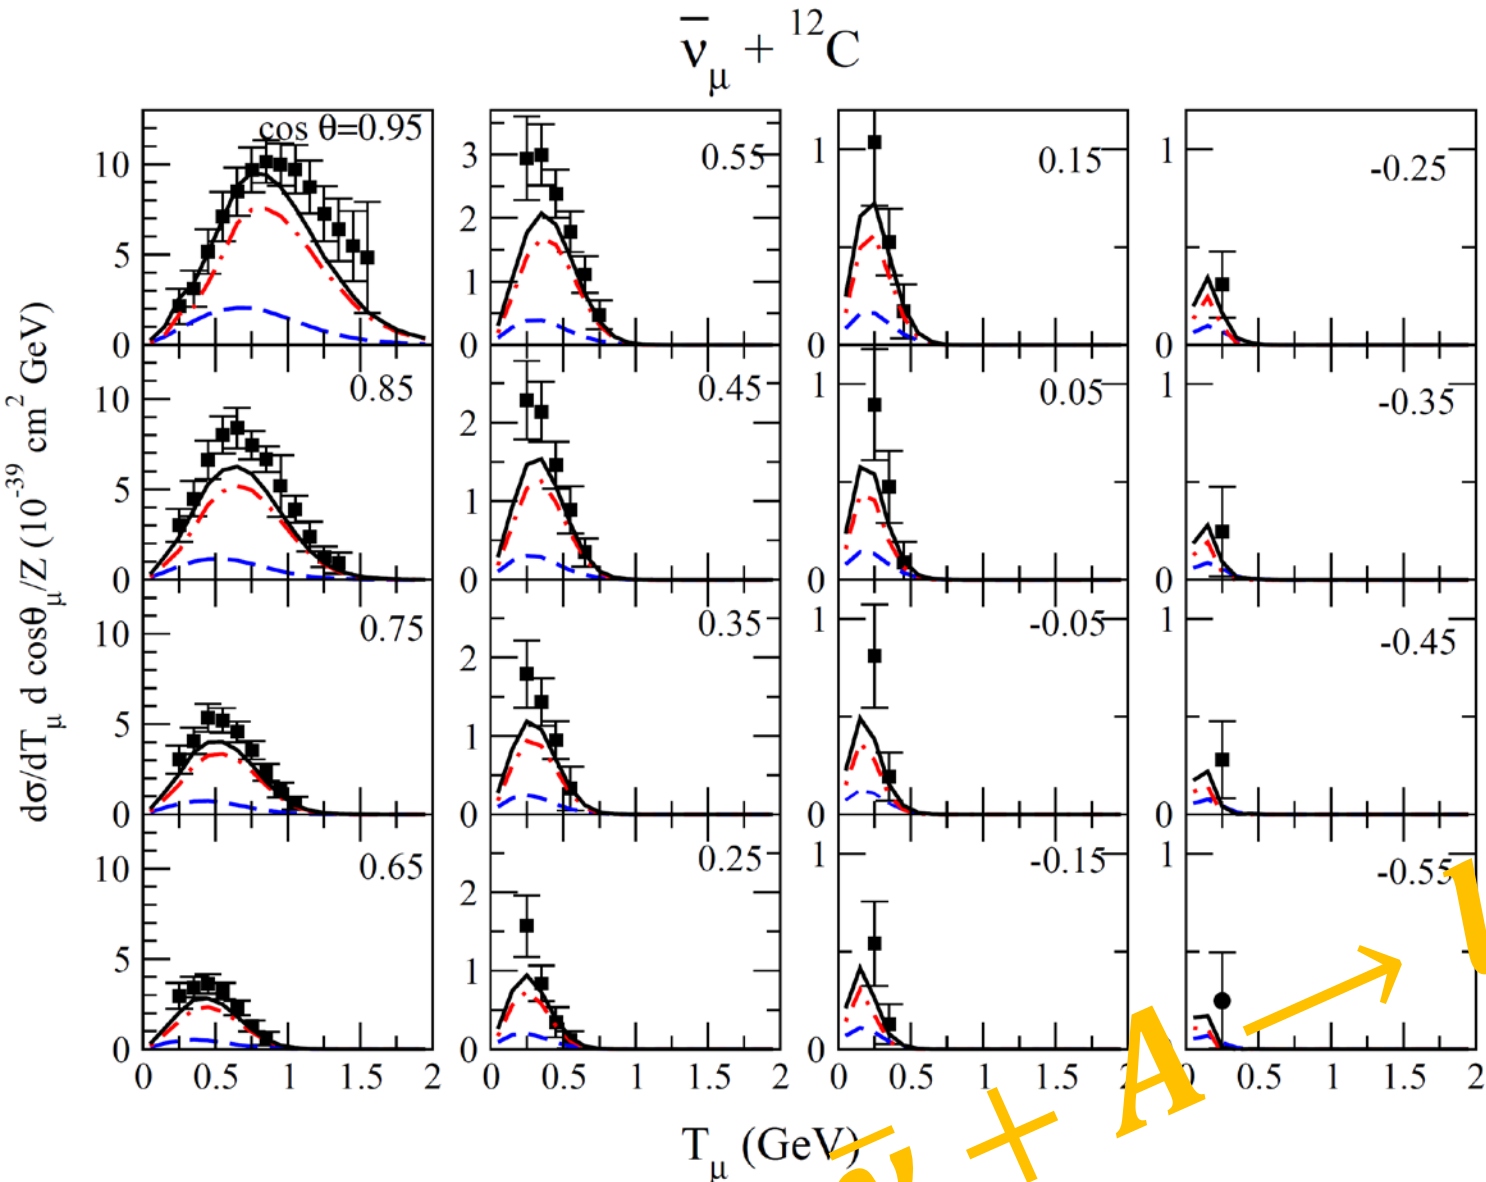

Model	Scale	M_A (GeV)	$\frac{\chi^2}{\#bins}$

MB estimate of total normalization error 10.7%

† : As suggested by Sobczyk et al. PRC 82, 045502

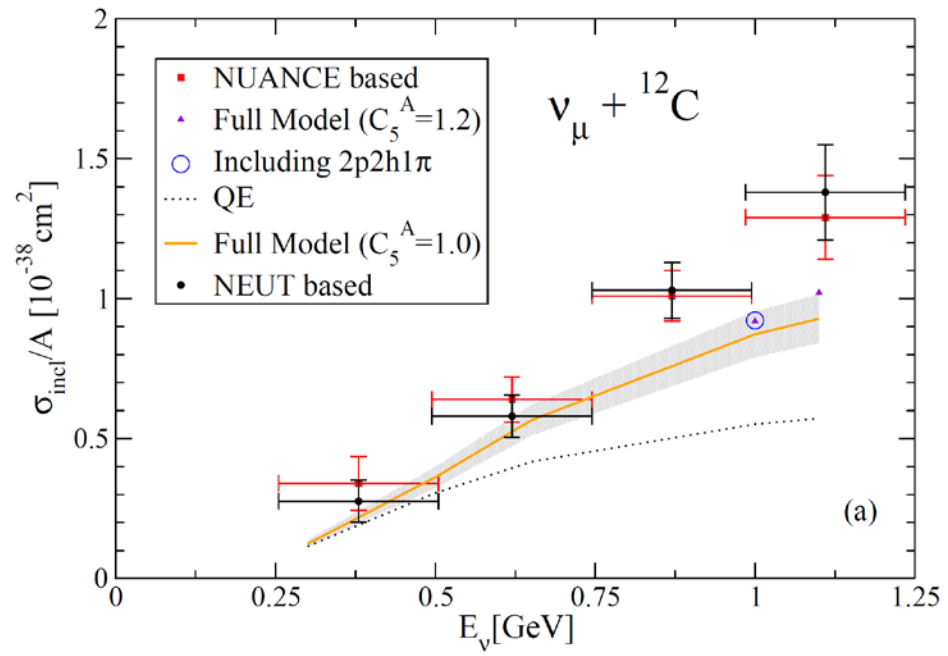

Neither 2p2h contributions nor RPA effects alone describe the MB 2D dataset, which is however described by the combination of both nuclear mechanisms!

$M_A \sim 1.03 \text{ GeV}$

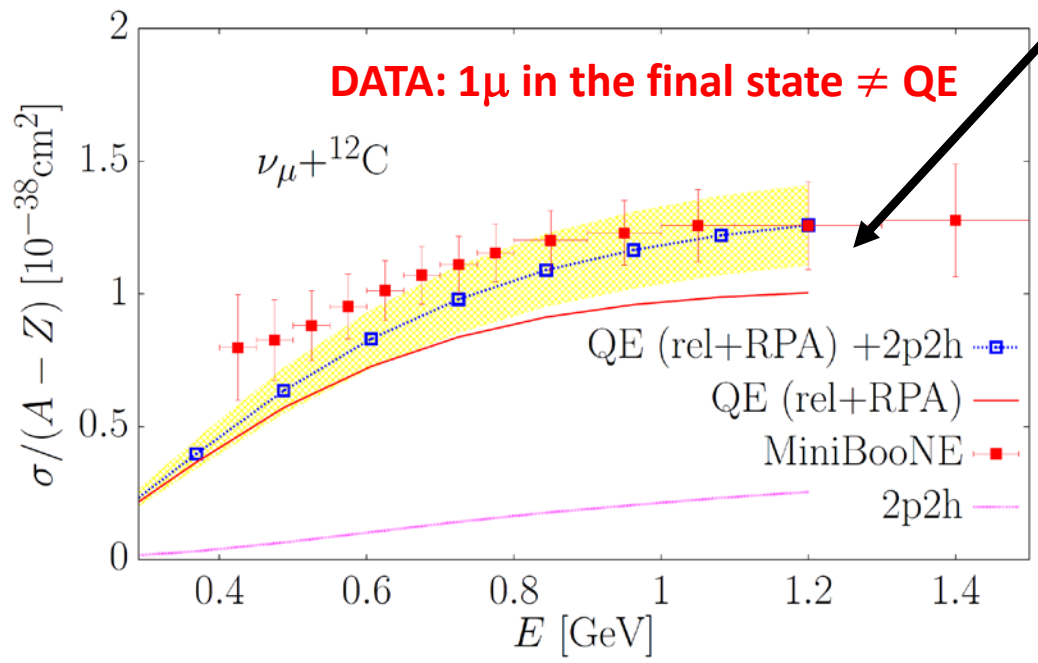

- **Antineutrino distributions are more forward peaked**
- **Relative importance of 2p2h contributions in ν and $\bar{\nu}$ are similar**

$\nu + A$
 $\bar{\nu} + X$

Inclusive

some discrepancies between QE+2p2h and MiniBooNE flux-unfolded cross section caused by the neutrino energy reconstruction procedure used to pass from flux-folded to flux-unfolded data

QE-like!

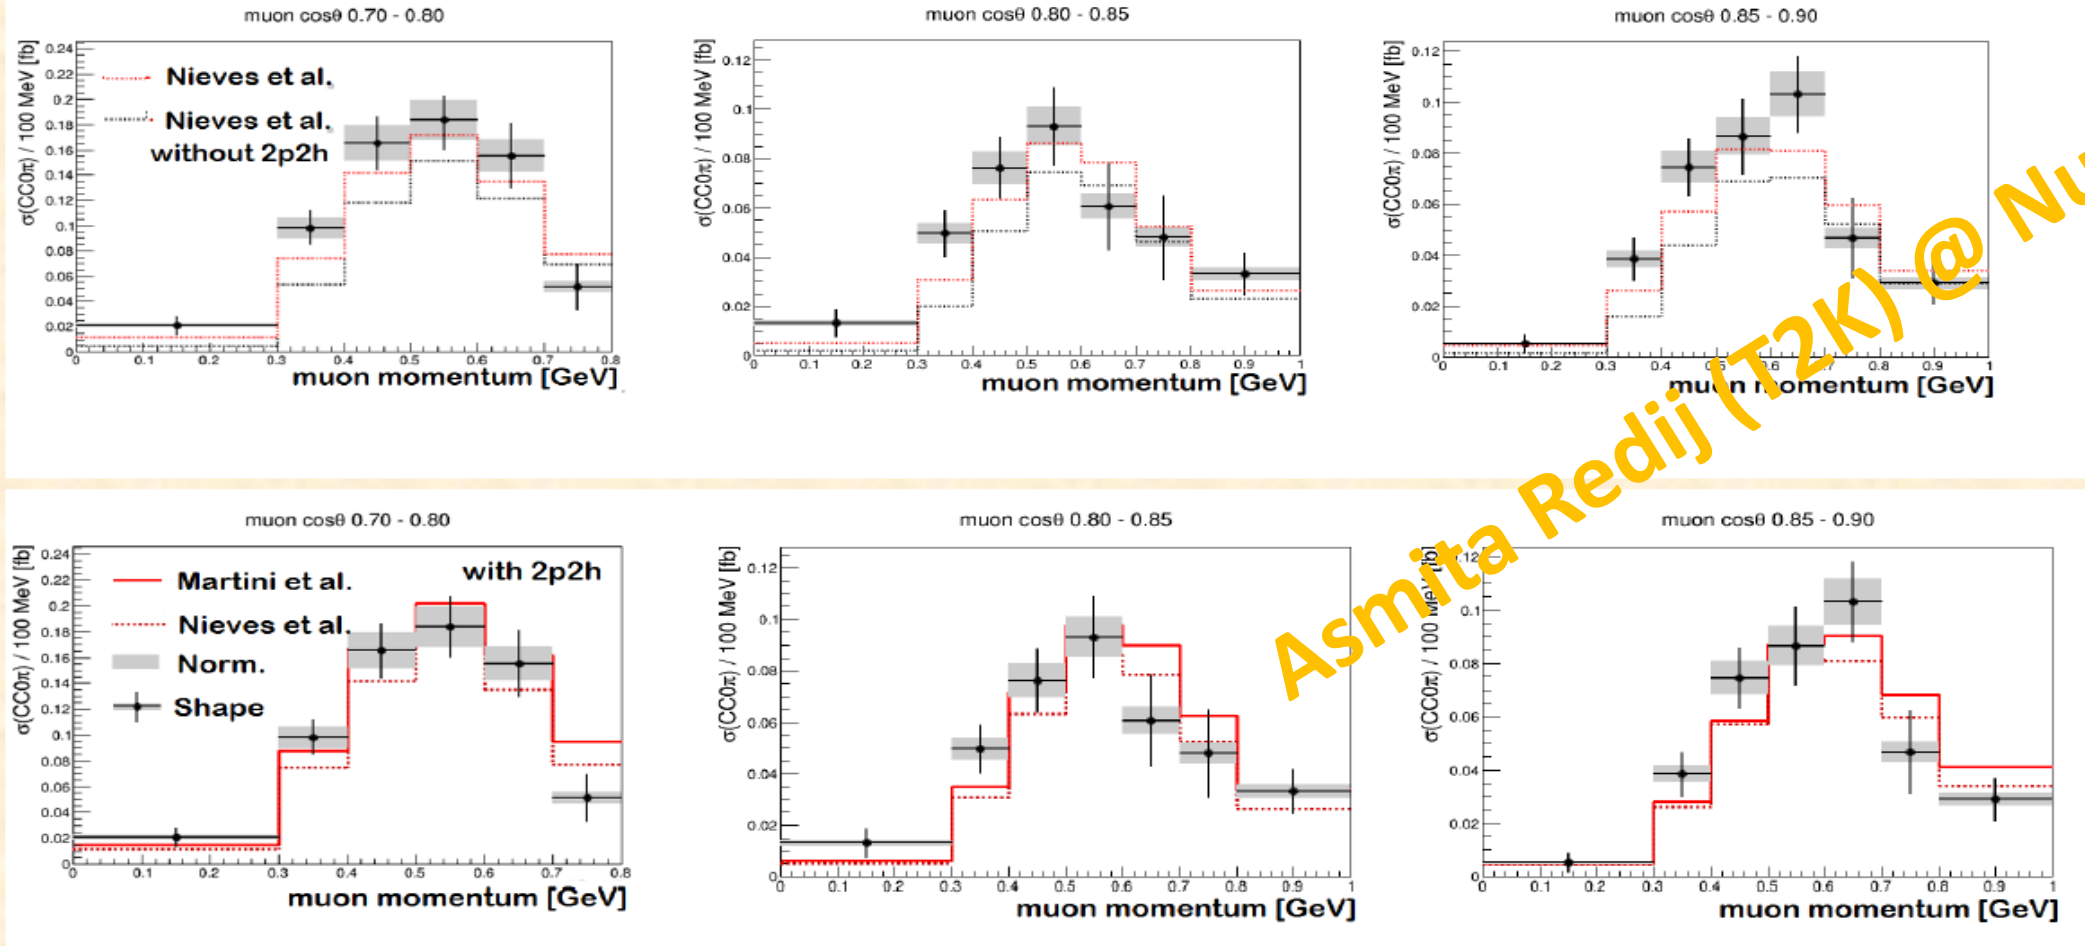

MB neutrino and antineutrino 2D dataset is, however, reasonably described by the combination of both nuclear mechanisms

the algorithm used to reconstruct the neutrino energy is not adequate when dealing with quasielastic-like events, and a distortion of the total flux-unfolded cross-section shape is produced. This amounts to a redistribution of strength from high to low energies, which gives rise to a sizable excess (deficit) of low (high) energy neutrinos. This distortion of the shape leads to a good description of the MiniBooNE unfolded charged current quasielastic-like cross sections published by the MiniBooNE Collaboration

JN, F. Sánchez, I Ruiz-Simo, M.J. Vicente-Vacas PD85 (2012) 113008

Comparison with nuclear models

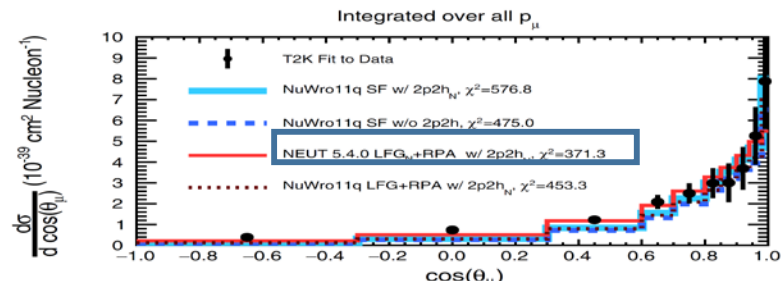

Measurement favor presence of 2p2h interactions.

Asmita Redij (T2K) @ NuInt 2015

— NEUT 5.4.0 LFG $_N$ +RPA w/ 2p2h $_N$, $\chi^2=371.3$

Measurement of the cross section as a function of the proton multiplicity (top left) and as a function of proton and muon kinematics where there is exactly one proton (with momentum above 500 MeV).

good agreement with T2K data!

T2K: PRD 98 032003 (2018)

The data make clear two distinct multinucleon effects that are essential for complete modeling of neutrino interactions at low momentum transfer. The $2p2h$ model tested in this analysis improves the description of the event rate in the region between QE and Δ peaks, and the rate for multiproton events, but does not go far enough to fully describe the data. Oscillation experiments sensitive to energy reconstruction effects from these events must account for this event rate. The cross section presented here will lead to models with significantly improved accuracy.

**MINERvA: CCQE-like
(hadron calorimetry)**

PRL 116, 071802 (2016)

MINERvA: $\bar{\nu}$ -CCQE-like

...addition of RPA and 2p2h effects to the simulation substantially improves agreement with the MINERvA QE-like data over default GENIE. Addition of either RPA or 2p2h alone is not sufficient. However, substantial discrepancies between the improved model and data remain, indicating that more model development is needed.

C.E. Patrick et al.,
PRD97 (2018) 052002

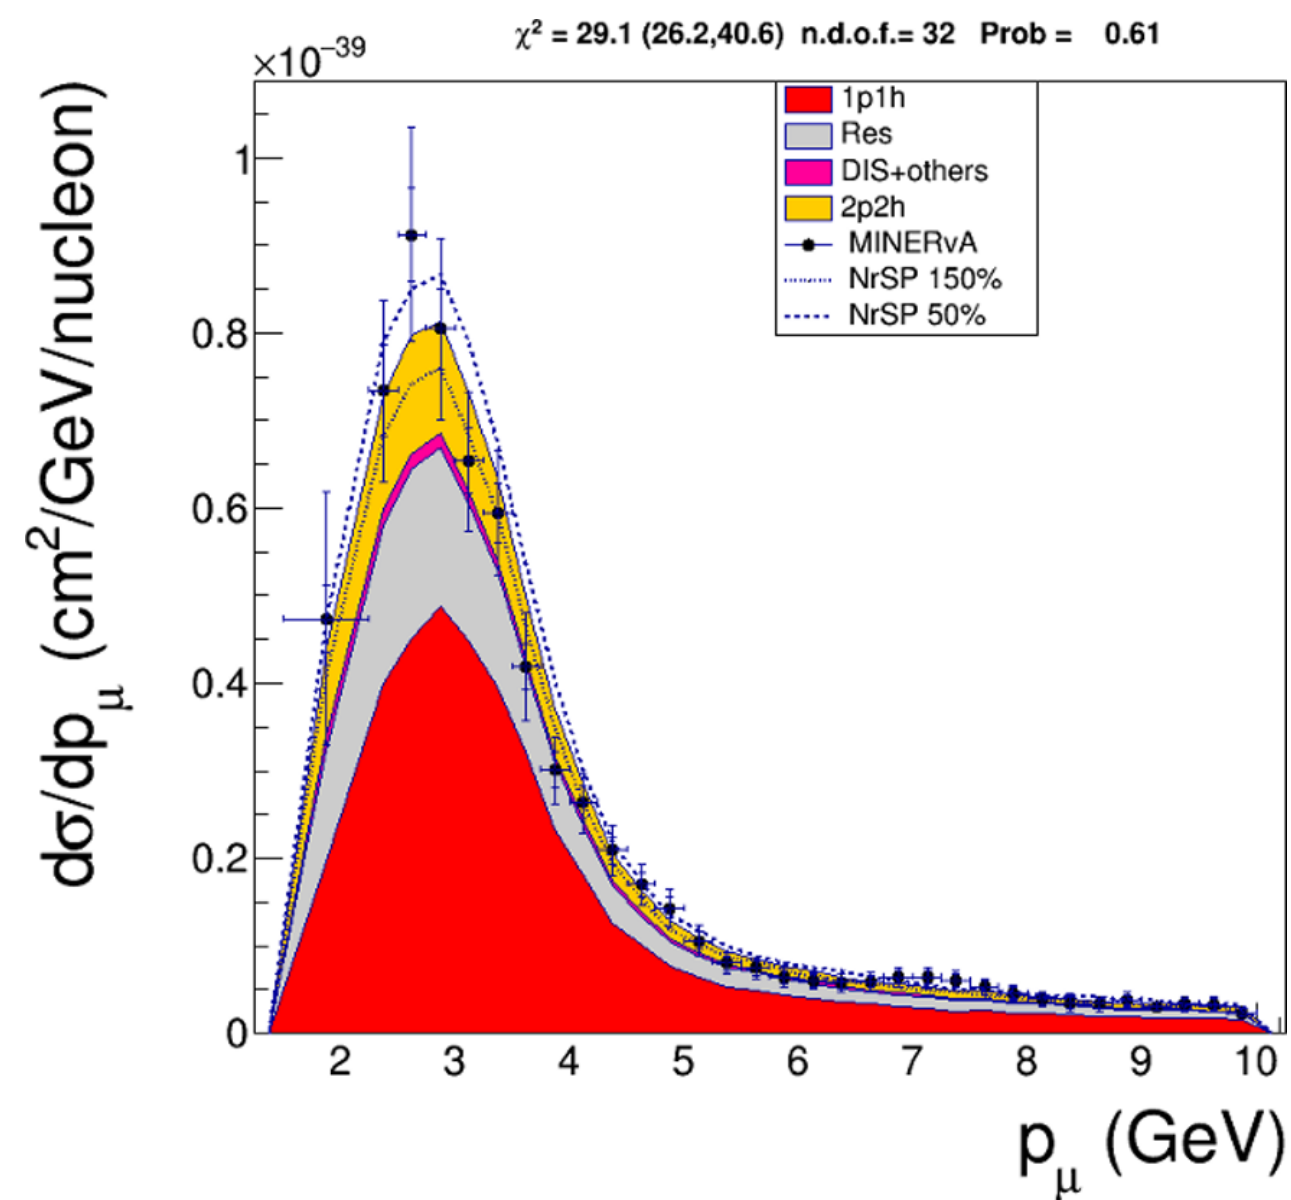

Hadronic energy spectrum: The IFIC Valencia 2p2h model increases the predicted event rates, but not enough. This process is increased further with an empirical enhancement based on MINERvA inclusive neutrino data. The additional events are from weighting up the generated 2p2h events according to a two-dimensional Gaussian in true q_0 , q_3 , whose six parameters are fit to the neutrino data version of these distributions. This enhancement adds 50% to the predicted 2p2h strength, but it targets the event rate in the kinematic region between the CCQE and Δ peaks where the rate doubles.

MINERvA (Antineutrino Charged-Current Reactions on Hydrocarbon with Low Momentum Transfer):
PRL (2018) 221805

We therefore enhance the 2p2h prediction from the Nieves model in a specific region. Integrated overall phase space the rate of 2p2h is increased by 53%.

³*Université de Genève, Faculté des Sciences, Département de Physique Nucléaire et Corpusculaire (DPNC) 24, Quai Ernest-Ansermet, CH-1211 Genève 4, Switzerland*

(Received 24 February 2020; revised 29 May 2020; accepted 10 July 2020; published 3 August 2020)

We present results of an updated calculation of the two particle two hole (2p2h) contribution to the neutrino-induced charge-current cross section. We provide also some exclusive observables, interesting from the point of view of experimental studies, e.g. distributions of momenta of the outgoing nucleons and of available energy, which we compare with the results obtained within the NEUT generator. We also compute, and separate from the total, the contributions of 3p3h mechanisms. Finally, we discuss the differences between the present results and previous implementations of the model in MC event generators, done at the level of inclusive cross sections, which might significantly influence the experimental analyses, particularly in the cases where the hadronic observables are considered.

previous
results are
confirmed

Conclusions

- We have presented a theoretical description of effects produced by the inclusion of SFs, which account for the change of the dispersion relations of the interacting nucleons embedded in a nuclear medium.
- SFs are responsible for the quenching of the QE peak, produce a spreading of the strength of the response functions to higher energy transfers and shift the peak position in the same direction. The overall result is a decrease of the integrated cross sections and a considerable change of the differential shapes.
- RPA effects in integrated decay rates or cross sections become significantly smaller when SF corrections are also taken into account, in sharp contrast to the case of a free LFG where they lead to large reductions, even of around 40%.
- We have analyzed the MiniBooNE CCQE 2D cross section data using a theoretical model that has proved to be quite successful in the analysis of nuclear reactions with electron, photon and pion probes and contains no additional free parameters.

- RPA and multinucleon knockout have been found to be essential for the description of the data.
- MiniBooNE ν and $\bar{\nu}$ CCQE-like data are fully compatible with former determinations of M_A in contrast with several previous analyses. We find, $M_A = 1.08 \pm 0.03$ GeV.
- The MiniBooNE ν_μ flux could have been underestimated ($\sim 10\%$).
- Because of the multinucleon mechanism effects, the algorithm used to reconstruct the neutrino energy is not adequate when dealing with QE-like events.
- The inclusion of nucleon-nucleon correlation effects in the RPA series yields a much larger shape distortion toward relatively more high- q^2 interactions, with the 2p2h component filling in the suppression at very low q^2 .

2018-2021: 2p2h+RPA nuclear model describes fairly well MINERVA-T2K inclusive CC0 π data. Problems with MINERvA persist in available hadron energy distributions (2p2h contributions need to be substantially enhanced!), perhaps related with pion production data...

Comparison of σ_μ/σ_e in ^{40}Ar 

neutrino

Comparison of σ_μ/σ_e in ^{40}Ar 

antineutrino

$$^{40}\text{Ar} \quad \sigma_\mu/\sigma_e$$

- Important deviations from 1 ($150 \text{ MeV} < E_\nu < 400 \text{ MeV}$)
- SFs & RPA effects strongly affect the ratio and become essential to perform a correct analysis of appearance neutrino oscillation events in LBE.

Final remark:

Nuclear effects lead to sizable uncertainties on the neutrino nucleus cross sections at low $-q^2 = Q^2 < 1 \text{ GeV}^2$

It is important to incorporate these effects in event generators (GENIE, etc..)
