DIS 2022, Santiago de Compostela
Electroweak physics

- Current measurements of electroweak observables are consistent with the SM predictions (with some tensions)
- Precision measurements of these quantities allow to search for new physics effects
- Challenging both from the theoretical (modelling) and experimental points of view

\[
m_W^2 \left( 1 - \frac{m_W^2}{m_Z^2} \right) = \frac{\pi \alpha}{\sqrt{2} G_F} (1 + \Delta)
\]

\[
\sin^2 \theta_W = 1 - \frac{m_W^2}{m_Z^2} \quad \Gamma_W \propto G_F m_W^3
\]

[EPJC 78, 675 (2018)]

Higher order corrections
The LHCb detector to study EW signatures

- Detector in the forward region with excellent momentum and vertex resolutions
- Coverage is complementary to ATLAS and CMS (with some overlapping at low pseudorapidity)

\[ \sigma_{\text{IP}} = (15 + 29/p_T^{[\text{GeV}]) \mu m} \]

\[ \varepsilon_{\text{ID}}^\mu = 90\% \text{ for } 5\% h \to e \text{ mis-id prob.} \]

\[ \varepsilon_{\text{ID}}^\mu = 97\% \text{ for } 1\%-3\% \pi \to \mu \text{ mis-id prob.} \]
The $W$ mass measurement
Single event signature at LHCb

Precise modelling of the production of $W$ bosons and backgrounds

Must carefully determine the momentum of the outgoing muon

Get rid of background with kinematic and isolation requirements

Not reconstructed at LHCb
Analysis strategy

- Measure the W boson mass by studying the transverse momentum spectrum of the outgoing muon
- Uncertainty from PDFs is anticorrelated to that of ATLAS/CMS ⇒ LHC experiments can achieve a sensitivity closer to the global EW fit (~7 MeV)

CMS & ATLAS

Analysis using 2016 data only

[JHEP 01 (2022) 036], [LHCB-PAPER-2021-024]
The W cross-section

\[
\frac{d\sigma}{dp_T^W dy dM d\cos \vartheta d\varphi} = \frac{3}{16\pi} \frac{d\sigma^{unpol.}}{dp_T^W dy dM}
\]

(At order $\alpha_s^2$)

\[
\begin{align*}
&\{ (1 + \cos^2 \vartheta) + A_0 \frac{1}{2} (1 - 3 \cos^2 \vartheta) + A_1 \sin 2\vartheta \cos \varphi \\
&+ A_2 \frac{1}{2} \sin^2 \vartheta \cos 2\varphi + A_3 \sin \vartheta \cos \varphi + A_4 \cos \vartheta \\
&+ A_5 \sin^2 \vartheta \sin 2\varphi + A_6 \sin 2\vartheta \sin \varphi + A_7 \sin \vartheta \sin \varphi \}
\end{align*}
\]

Small dependency on the angular coefficients for the W mass measurement at LHCb except for $A_3$

(See talk by Menglin Xu for more details)
Simulating signal decays

POWHEG + Pythia gives the best description of the unpolarized cross-section and is chosen as the baseline generator

- Varied success with other generators, used to determine systematic uncertainties

- DYTURBO performs well at reproducing the angular cross-section

[Tune of $\alpha_s$ and intrinsic $k_T$]

\[\text{POWHEG + Pythia} \]

\[\text{DYTurbo} \]

\[\text{Before fit} \]

\[\text{After fit} \]

\[\text{LHCb} \]

\[1.7 \text{ fb}^{-1} \]

\[\text{[JHEP 01 (2022) 036], [LHCB-PAPER-2021-024]} \]
Alignment and calibration of the detector

- The W mass determination is highly sensitive to misalignments and misalignments of the detector
- Offline tools used to improve the determination of the transverse momentum

\[ M^\pm = \sqrt{2p_T^+ p_T^- (1 - \cos \theta)} \]

Inspired by [Phys. Rev. D 91, 072002](https://journals.aps.org/prd/91/072002)
Backgrounds

- Most of them modelled from dedicated simulated samples
  - Single-top, quark/anti-quark (t, b, c), Z/W decays, Drell-Yan
  - Cross-sections normalized to the W
- Description of the QCD background (decays-in-flight) obtained from data
  - Sample with inverted muon-identification requirements
  - Weight and parametrize the data using a Hagedorn distribution
- Accurately describes the Jacobian peak (region with highest sensitivity to $m_W$)
## Systematic uncertainties

Average of NNPDF31, CT18 and MSHT20 systematic uncertainties

Envelope of five different models

Uncertainty due to scale variations

Envelope of the QED FSR from Pythia, Photos and Herwig. Additional correction from PowhegEW

Already thinking of ways to improve most of these uncertainties!
The W mass fit

Including 2017 + 2018 data ⇒ < 20 MeV

New strategies/tools?

Improvements to the physics modelling

\[ m_W = 80354 \pm 23_{\text{stat}} \pm 10_{\text{exp}} \pm 17_{\text{theory}} \pm 9_{\text{PDF}} \text{ MeV} \]
The current picture of the measurement

- Striking result from the CDF II collaboration in early April [Science, 376, 6589, (136-136), (2022)], with unprecedented precision
- $7\sigma$ away from the electroweak fits, and in tension with other experimental results
- Open questions now being raised:
  - Resolution, efficiency and detector response
  - Physics modelling (proton-proton, proton-antiproton, PDFs, ...)
- Encouraging the full LHC combination
Other Electroweak measurements
Angular coefficients

- Study of dimuon decays around the Z peak using 2016-2018 data
- Z production studied in the past at LHCb [EPJC 71:1600, 2011], but the angular information had not been analysed yet
- Valuable input to understand momentum-spin correlations of the proton

Sensitive to the weak-mixing angle; not reported

\[
\frac{d\sigma}{d\cos \theta d\phi} \propto (1 + \cos^2 \theta) + \frac{1}{2} A_0 (1 - 3 \cos^2 \theta) + A_1 \sin 2\theta \cos \phi + \frac{1}{2} A_2 \sin^2 \theta \cos 2\phi + A_3 \sin \theta \cos \phi + A_4 \cos \theta + A_5 \sin^2 \theta \sin 2\phi + A_6 \sin 2\theta \sin \phi + A_7 \sin \theta \sin \phi
\]

Fixed to zero due to small number of candidates at high transverse momentum

(See talk by Menglin Xu for more details)
Forward-backward asymmetry in Z decays

- Test of vector and axial-vector couplings in the SM, which induce a forward-backward asymmetry in Z boson decays
- Dependency with the weak mixing angle
- The asymmetry must be measured with respect to the direction of motion of the quarks
  ○ Assume that quarks travel in the direction of the Z boson
- Possibility to beat LEP + SLD measurements in the HL-LHC [CERN-LHCC-2018-027]
Prospects and summary
Prospects and summary

- LHCb has proved to be competitive with the previous and current experiments for a precise W mass measurement.
- The new result from the CDF-II collaboration constitutes a drastic change to the current scenario.
  - Pushes the LHC towards releasing a combined result and theorists towards a better understanding of the physics modelling.
- LHCb also offers a unique opportunity to study other EW observables in the forward region, usually complementary to other experiments.

Exciting times ahead of us!
Thank you!

LHCb luminosity

[Diagram showing LHCb luminosity over time with data points for different years and energy levels.]
Charge-dependent curvature biases

- The analysis relies highly on the detector alignment
  - Misalignment of 10µm translates into a O(50MeV) shift
- Default LHCb alignment and calibration not suitable to study candidates with high transverse momentum
- Need to re-run the alignment and calibration offline using Z decays
- Avoid double bias from the momentum resolution using the pseudo-mass method

\[ M^\pm = \sqrt{2p^\pm p_T^\pm p_T^\mp (1 - \cos \theta)} \]

Inspired by Phys. Rev. D 91, 072002
The simulation process (PDF set)

- PDFs chosen from three different recent sets
  - CT18: [Phys. Rev. D 103, 014013]

- The result is an average of the three
Selections

- EW physics with leptons in the final state can be done at LHCb with simple selections based on the transverse momentum, impact parameter, isolation and particle identification

- Selection biases studied in data and simulation for Z and Y(1S) decays (isolation biases only studied in the former)
  - Associated systematic uncertainties determined by varying the binning scheme, parametrizations and selections

\[
I = \sum_i^n p_T^i \in \text{cone}
\]

\[
\Delta R = \sqrt{\Delta \eta^2 + \Delta \phi^2 \text{ (rad}^{-2})}
\]
Determining the efficiencies

Three main sources of acceptance biases:

- Trigger efficiencies
- Muon-identification efficiencies
- Isolation requirements

Corrections predominantly at the percent level
