The Drell-Yan q_T Spectrum and Its Uncertainty at N^3LL'

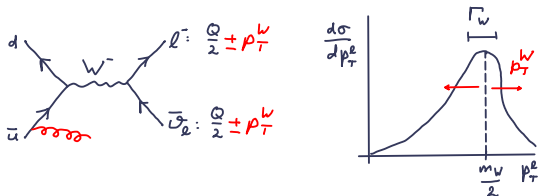

[to appear soon]

in collaboration with
G. Billis, M. Ebert, F. Tackmann

Motivation: Measuring m_W at the LHC any hadron collider

Want to measure m_W , but too much information about the neutrino is lost:

\Rightarrow Need precise theory predictions for $d\sigma/dp_T^Z$ and $d\sigma/dp_T^W$ to model the p_T^W spectrum using precisely measured p_T^Z as input

$$\begin{aligned}
 m_W^{\text{ATLAS}} &= 80370 \pm 7_{\text{stat.}} \\
 &\quad \pm 11_{\text{exp. syst.}} \\
 &\quad \pm 14_{\text{theory}} \text{ MeV} \\
 &= 80370 \pm 19 \text{ MeV}
 \end{aligned}$$

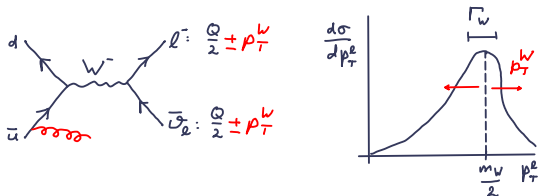

[ATLAS, 1701.07240]

$$\begin{aligned}
 m_W^{\text{LHCb}} &= 80354 \pm 23_{\text{stat.}} \\
 &\quad \pm 10_{\text{exp. syst.}} \\
 &\quad \pm 17_{\text{theory}} \\
 &\quad \pm 9_{\text{PDF}} \text{ MeV} \\
 &= 80354 \pm 32 \text{ MeV}
 \end{aligned}$$

[LHCb, 2109.01113]

Motivation: Measuring m_W at the LHC any hadron collider

Want to measure m_W , but too much information about the neutrino is lost:

\Rightarrow Need precise theory predictions for $d\sigma/dp_T^Z$ and $d\sigma/dp_T^W$ to model the p_T^W spectrum using precisely measured p_T^Z as input

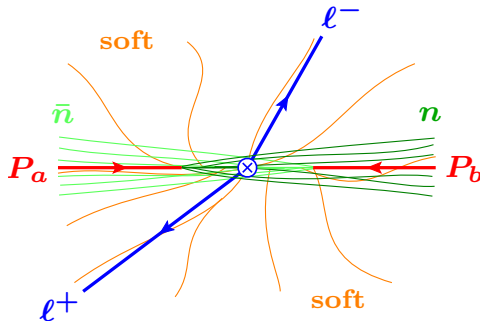

Challenges Opportunities for theory

- Need sub-percent precision on $d\sigma/dp_T^Z$ and $d\sigma/dp_T^W$
 - Leave no stone unturned: **QCD three-loop corrections**, QED radiative corrections, quark mass effects, **parametric and nonperturbative uncertainties**
- Resum singular terms & large logarithms $\frac{\alpha_s^n}{q_T} \left(\ln \frac{q_T}{Q} \right)^{2n-1}$ to all orders in α_s

Perturbative ingredients: Factorized singular cross section at N^3LL'

$$\frac{d\sigma}{dq_T} = \frac{d\sigma_{\text{fact}}^{\text{res}}}{dq_T} + \left[\frac{d\sigma_{\text{full}}^{\text{FO}}}{dq_T} - \frac{d\sigma_{\text{fact}}^{\text{FO}}}{dq_T} \right] \equiv \frac{d\sigma_{\text{fact}}^{\text{res}}}{dq_T} + \frac{d\sigma_{\text{fact}}^{\text{nons}}}{dq_T}$$

$$\begin{aligned} \frac{d\sigma_{\text{fact}}}{dQ dY dq_T} &= \sum_q H_{q\bar{q}}(Q, \mu) q_T \int_0^\infty db_T b_T J_0(q_T b_T) \\ &\times f_q^{\text{TMD}}(x_a, b_T, \mu, \zeta) f_{\bar{q}}^{\text{TMD}}(x_b, b_T, \mu, \zeta) + (q \leftrightarrow \bar{q}) \end{aligned}$$

Perturbative ingredients: Factorized singular cross section at N^3LL'

$$\frac{d\sigma}{dq_T} = \frac{d\sigma_{\text{fact}}^{\text{res}}}{dq_T} + \left[\frac{d\sigma_{\text{full}}^{\text{FO}}}{dq_T} - \frac{d\sigma_{\text{fact}}^{\text{FO}}}{dq_T} \right] \equiv \frac{d\sigma_{\text{fact}}^{\text{res}}}{dq_T} + \frac{d\sigma_{\text{fact}}^{\text{nons}}}{dq_T}$$

$$\begin{aligned} \frac{d\sigma_{\text{fact}}}{dQ dY dq_T} &= \sum_q H_{q\bar{q}}(Q, \mu) q_T \int_0^\infty db_T b_T J_0(q_T b_T) \\ &\quad \times f_q^{\text{TMD}}(x_a, b_T, \mu, \zeta) f_{\bar{q}}^{\text{TMD}}(x_b, b_T, \mu, \zeta) + (q \leftrightarrow \bar{q}) \end{aligned}$$

Implemented in SCETlib C++ numerical library [Ebert, JKLM, Tackmann]:

- Three-loop **hard** function [Baikov et al. '09; Lee et al. '10; Gehrmann et al. '10, '20; Czakon et al. '21]
- Three-loop matching of **TMD PDFs** onto collinear PDFs [Li, Zhu, '16; Luo, Yang, Zhu, Zhu '19; Ebert, Mistlberger, Vita '20]
 - ▶ Prediction includes complete three-loop RG boundary conditions (N^3LL')
 - ▶ Integral of spectrum is **N^3LO** -accurate
- Four-loop cusp, three-loop noncusp anomalous dimensions [Brüser, et al. '19; Henn et al. '20; v. Manteuffel et al. '20; Li, Zhu, '16; Vladimirov '16]
- Fiducial power corrections $\mathcal{O}(q_T/Q)$ resummed through exact acceptance [Resummation & use in subtraction: Ebert, JKLM, Stewart, Tackmann '20]
[See talk by Alessandro Guida on Tuesday for impact on PDF fits!]

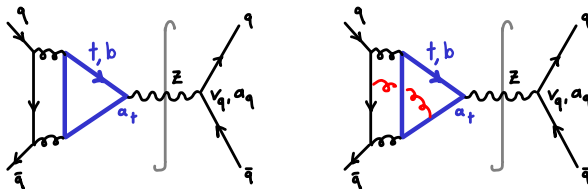

Perturbative ingredients: Factorized singular cross section at N³LL'

$$\frac{d\sigma}{dq_T} = \frac{d\sigma_{\text{fact}}^{\text{res}}}{dq_T} + \left[\frac{d\sigma_{\text{full}}^{\text{FO}}}{dq_T} - \frac{d\sigma_{\text{fact}}^{\text{FO}}}{dq_T} \right] \equiv \frac{d\sigma_{\text{fact}}^{\text{res}}}{dq_T} + \frac{d\sigma_{\text{fact}}^{\text{nons}}}{dq_T}$$

$$\begin{aligned} \frac{d\sigma_{\text{fact}}}{dQ dY dq_T} &= \sum_q H_{q\bar{q}}(Q, \mu) q_T \int_0^\infty db_T b_T J_0(q_T b_T) \\ &\quad \times f_q^{\text{TMD}}(x_a, b_T, \mu, \zeta) f_{\bar{q}}^{\text{TMD}}(x_b, b_T, \mu, \zeta) + (q \leftrightarrow \bar{q}) \end{aligned}$$

Implemented in SCETlib C++ numerical library [Ebert, JKLM, Tackmann]:

- Fiducial power corrections $\mathcal{O}(q_T/Q)$ resummed through exact acceptance [Resummation & use in subtraction: Ebert, JKLM, Stewart, Tackmann '20]
[See talk by Alessandro Guida on Tuesday for impact on PDF fits!]

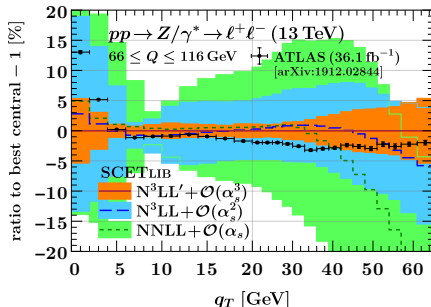

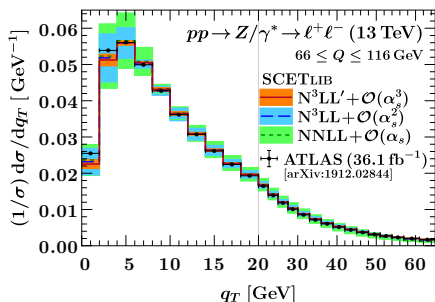

$$\begin{aligned}\frac{d\sigma_{\text{nons}}}{dq_T} &= \frac{d\sigma_{\text{full}}^{\text{FO}}}{dq_T} - \frac{d\sigma_{\text{sing}}^{\text{FO}}}{dq_T} \\ &= \frac{1}{q_T} \mathcal{O}\left(\frac{q_T^2}{Q^2}\right)\end{aligned}$$

- In-house analytic implementation of all helicity structure functions at $\mathcal{O}(\alpha_s)$
- Fiducial Z +jet MC data at $\mathcal{O}(\alpha_s^2)$ from MCFM
[Campbell, Ellis, et al. '99, '15]
- Very recently: Precise fiducial Z +jet MC data at $\mathcal{O}(\alpha_s^3)$ from NNLOjet
[Chen et al., 2203.01565 – many thanks to the NNLOjet collaboration for providing the raw data.]

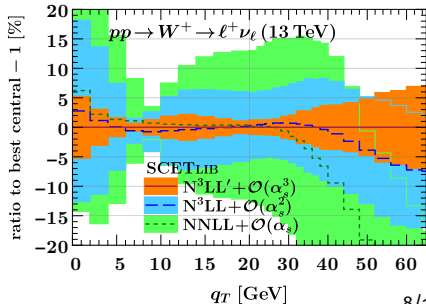

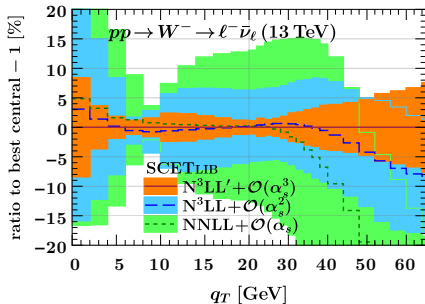

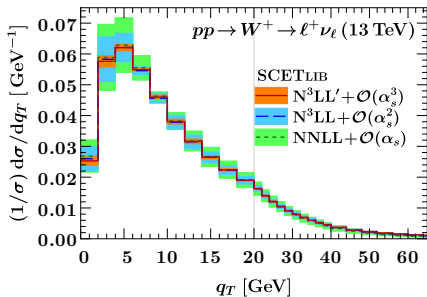

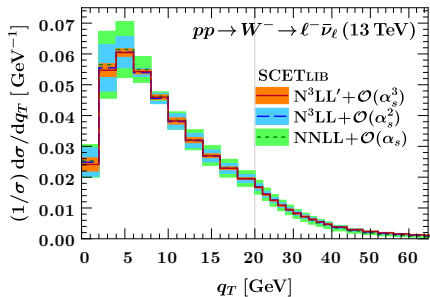

Results: Central prediction and perturbative convergence for $Z \rightarrow \ell^+ \ell^-$

- Central results use MSHT20nnlo with $\alpha_s(m_Z) = 0.118, n_f = 5$
- NNLO (= three-loop!) PDF evolution formally sufficient at N³LL':
 - DGLAP kernels are a noncusp anomalous dimension
 - Scale dependence formally cancels within three-loop TMD PDF function
 - Separate question whether PDFs should have been extracted using three-loop $\hat{\sigma}_{ij} \dots$

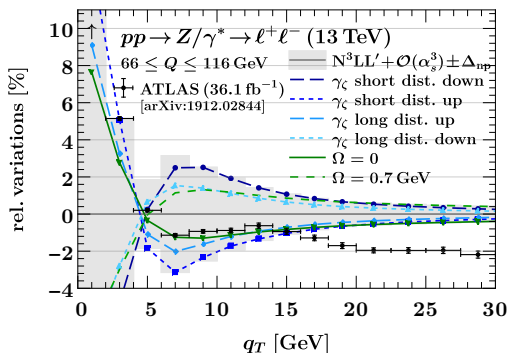

- Excellent perturbative convergence towards three-loop result
- Higher orders are covered by uncertainty estimate at lower orders
 [See backup for how they are estimated]

Results: Predictions for $W^\pm \rightarrow \ell\nu$

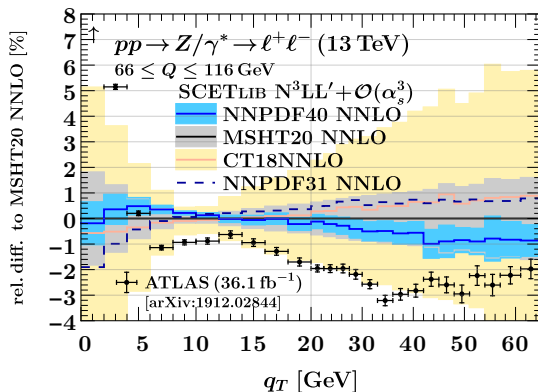

Results: Estimate of nonperturbative contributions

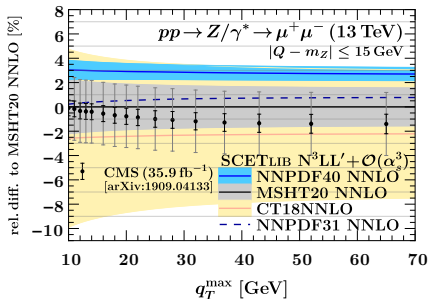

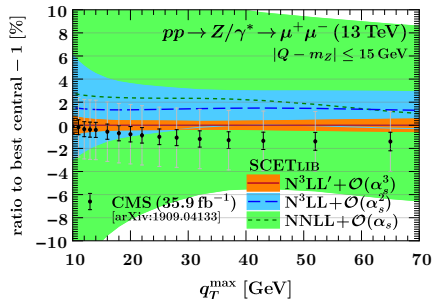

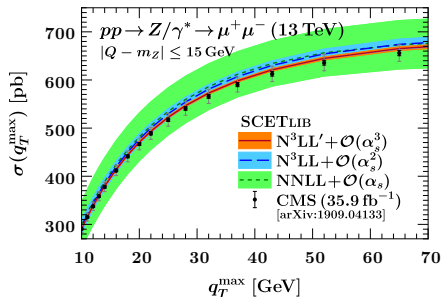

- Sources of nonperturbative corrections at small q_T :
 - Collins-Soper kernel (drives TMD evolution)
 - Intrinsic parton transverse momentum (TMD boundary conditions)
- Vary CS kernel model to cover spread of recent lattice results
[See backup for details; see also talk by P. Shanahan on Monday!]
- Taken at face value, the lowest bins seem to prefer *weaker* NP effects
- Overshoot data at $q_T = 20 - 30$ GeV, way outside NP effect strength

Results: Impact of PDFs on normalized Z spectrum

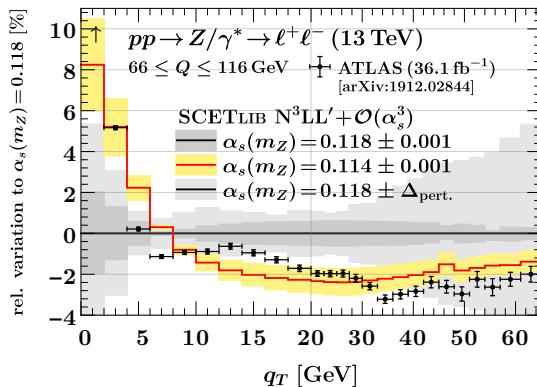

- Resummed 3-loop cross section is *analytic*, hold small $\alpha_s^{2,3}$ nonsingular fixed
 - Whole figure with complete PDF uncertainties at few 100 CPUh!
- PDF uncertainty largely cancels in normalized spectrum
- Cannot explain overshoot at $q_T = 20 - 30$ GeV

Cumulative unnormalized cross sections for N³LO PDF fits

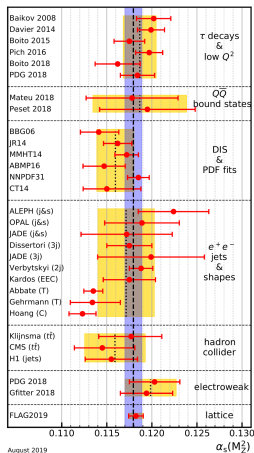

- Cumulative cross section distinguishes recent PDF sets
- Nonperturbative effects $\leq 0.1\%$ past $q_T^{\max} \sim 20 \text{ GeV}$
- Great target for N³LO PDF fits (limiting K -factors to $\sigma_{\text{nons!}}$)

Results: Impact of α_s on normalized Z spectrum

- Parametric uncertainty due to $\alpha_s(m_Z)$ on par with perturbative uncertainty
- Overshoot at $q_T = 20 - 30$ GeV is naturally explained by lower $\alpha_s(m_Z)$

This is not unprecedented ...

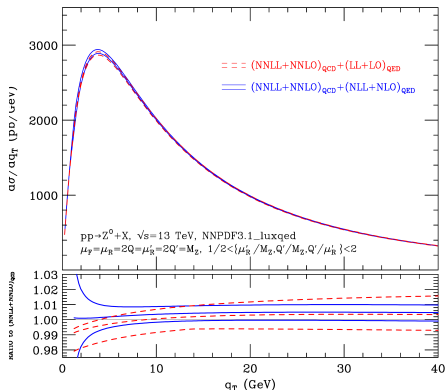

- Lower values of $\alpha_s(m_Z)$ have previously been reported in fits to e^+e^- event shapes (thrust and C parameter)
- DISCLAIMER: This was *not* an actual fit to $\{\alpha_s(m_Z), \Omega, \omega_\zeta^{(2)}\}$.
- Like $p_T^{Z/W}$, these are driven by all-order resummation ...

...but many caveats remain

Systematics at the theory frontier:

- QED resummation effects for on-shell Z well understood
[Bacchetta, Echevarria '18; Cieri, Ferrera, Sborlini '18; Billis, Tackmann, Talbert '19]
- Expected to be $\sim 1\%$, but would bring the tail up *more*

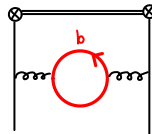

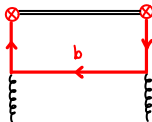

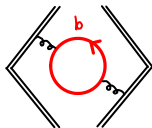

[Cieri, Ferrera, Sborlini 1805.11948]

...but many caveats remain

Systematics at the theory frontier:

- QED resummation effects for on-shell Z well understood
[Bacchetta, Echevarria '18; Cieri, Ferrera, Sborlini '18; Billis, Tackmann, Talbert '19]
 - Expected to be $\sim 1\%$, but would bring the tail up *more*
- In progress: Interface resummation with QED/weak corrections to full process with realistic lepton definitions (beyond mixed $\alpha\alpha_s$)
- Subleading power resummation & factorization for *nonsingular* cross section
[Progress towards doing this at least for $\mathcal{O}(q_T/Q)$ azimuthal correlations]
[Moos, Scimemi, Rodini, Vladimirov '21-'22; Ebert, Gao, Stewart '21 \rightarrow see talk by A. Vladimirov!]
- Full resummed treatment of mass effects/flavor thresholds
 - Expect impact on spectrum (and cumulative cross section) to be suppressed by $\# m_b^2/q_T^2$?

The Drell-Yan q_T Spectrum at N^3LL' and Its Uncertainty:

- Presented third-order predictions for Z and W^\pm q_T spectra at the LHC
 - ▶ Residual perturbative uncertainty at percent level in the peak
- Three-loop resummed SCETlib predictions are analytic & fast also with cuts
 - ▶ Assessing PDF and α_s uncertainties possible *directly at three loops*
 - ▶ Cumulative cross sections up to $q_T^{\max} \approx 40 \text{ GeV}$
extremely promising targets for N^3LO PDF fits (or reweighting)
- Even small changes $\alpha_s(m_Z) \pm 0.001$ strongly impact the peak shape
 - ▶ Effect for $q_T \leq 20 \text{ GeV}$ as important for TMD fits as collinear PDF uncertainty
- Intriguing hints that the data may prefer a lower value of $\alpha_s(m_Z)$ – stay tuned

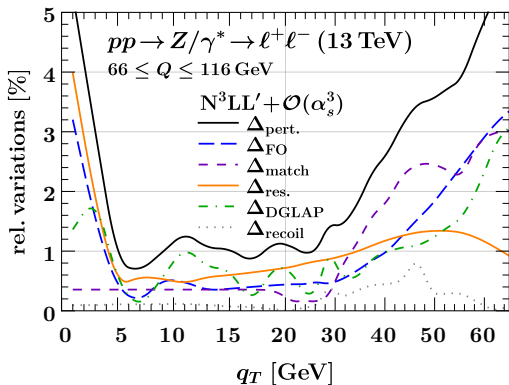

The Drell-Yan q_T Spectrum at N^3LL' and Its Uncertainty:

Breakdown of perturbative uncertainties

$$\Delta_{\text{pert.}} = \Delta_{\text{FO}} \oplus \Delta_{\text{match}} \oplus \Delta_{\text{res}} \oplus \Delta_{\text{DGLAP}} \oplus \Delta_{\text{recoil}}$$

- Fixed-order uncertainty, keeps resummed logarithms unchanged
- Estimated by standard variations of overall $\mu_R = \mu_{\text{FO}}$
- All scales (except μ_f) are chosen $\propto \mu_{\text{FO}}$, so e.g. μ_H/μ_S unchanged
- Frozen out at $b_T \lesssim 1/\Lambda_{\text{QCD}}$ by μ_X^* prescription \Rightarrow disentangled from NP

Breakdown of perturbative uncertainties

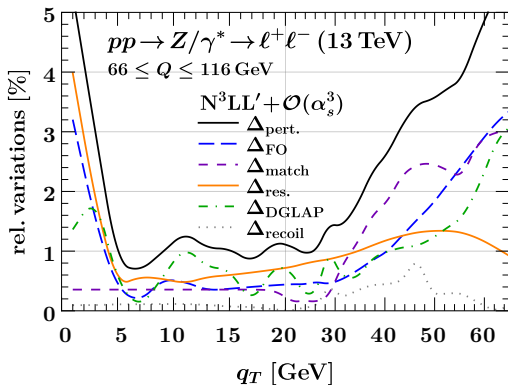

$$\Delta_{\text{pert.}} = \Delta_{\text{FO}} \oplus \Delta_{\text{match}} \oplus \Delta_{\text{res}} \oplus \Delta_{\text{DGLAP}} \oplus \Delta_{\text{recoil}}$$

- Uncertainty from **matching scheme** between resummed peak and fixed-order tail
- Estimated by varying the $x = q_T/Q$ transition points in hybrid profile as

$$\{x_1, x_2, x_3\} = \{0.3, 0.6, 0.9\} \pm \{0.1, 0.15, 0.2\}$$

- Checked that *inclusive* integrated cross section is recovered within Δ_{match}

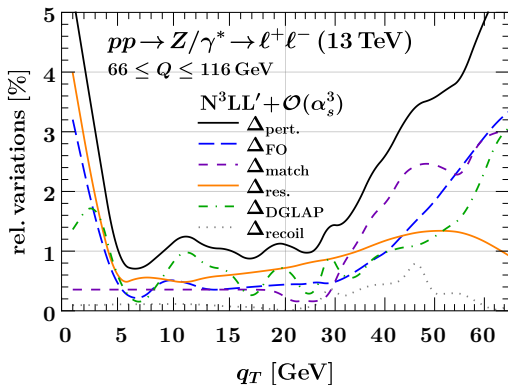

Breakdown of perturbative uncertainties

$$\Delta_{\text{pert.}} = \Delta_{\text{FO}} \oplus \Delta_{\text{match}} \oplus \Delta_{\text{res.}} \oplus \Delta_{\text{DGLAP}} \oplus \Delta_{\text{recoil}}$$

- Probes higher-order **resummed** logarithms
- Estimated by envelope of 36 different combinations of independently varying $\{\mu_B, \mu_S, \nu_B, \dots\}$ in $\sigma^{(0)} = H B \otimes B \otimes S$
- Also frozen out at $b_T \lesssim 1/\Lambda_{\text{QCD}}$ by μ_X^* prescription \Rightarrow disentangled from NP

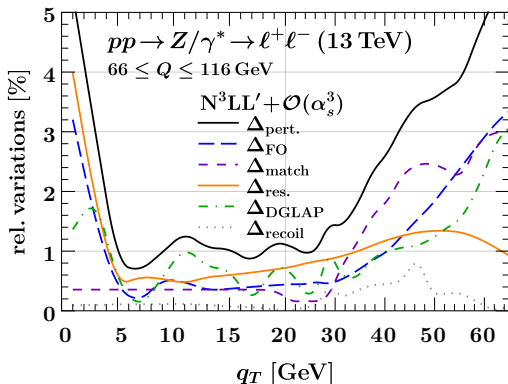

Breakdown of perturbative uncertainties

$$\Delta_{\text{pert.}} = \Delta_{\text{FO}} \oplus \Delta_{\text{match}} \oplus \Delta_{\text{res}} \oplus \Delta_{\text{DGLAP}} \oplus \Delta_{\text{recoil}}$$

- Estimate of missing higher orders (four loops) in **DGLAP** running
- Estimated both in peak and tail by joint variations of $\mu_f(b_T, q_T, Q)$ and $\mu_F(Q)$
- Oscillatory due to b_T -space features at uncanceled m_b threshold

Breakdown of perturbative uncertainties

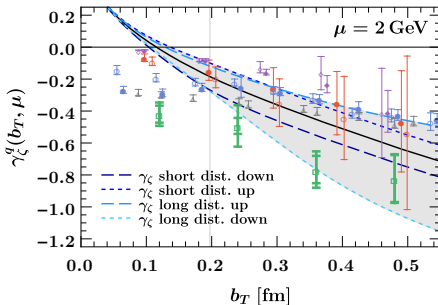

$$\Delta_{\text{pert.}} = \Delta_{\text{FO}} \oplus \Delta_{\text{match}} \oplus \Delta_{\text{res}} \oplus \Delta_{\text{DGLAP}} \oplus \Delta_{\text{recoil}}$$

- RPI-I transformation of n_a^μ, n_b^μ in $W_{\text{LP}}^{\mu\nu} \sim g_\perp^{\mu\nu}(n_a, n_b)$
- Induces $\mathcal{O}(q_T^2/Q^2)$ change in spectrum due to fiducial cuts on $L_{\mu\nu}$
 [Ebert, JKLM, Stewart, Tackmann '20]
- Equivalent to changing “recoil prescription”/choice of Z rest frame by $\mathcal{O}(q_T/Q)$

Nonperturbative model for the Collins-Soper kernel

$$\frac{1}{2}\gamma_{\nu,\text{NP}}^q(b_T) = \gamma_{\zeta,\text{NP}}^q(b_T) = c_{\zeta}^i \tanh\left(\frac{\omega_{\zeta,i}^2}{|c_{\zeta}|} b_T^2\right) = \text{sgn}(c_{\nu}^i) \omega_{\zeta,i}^2 b_T^2 + \mathcal{O}(b_T^4)$$

- Vary either ω_{ζ} (“short distance”) or c_{ζ} (“long distance”) to cover lattice results
[Collection of lattice data from Shanahan, Wagman, Zhao, 2107.11930 → see talk by P. Shanahan]
- Pick central value of $\text{sgn}(c_{\nu}^i) \omega_{\zeta,i}^2 (1 \pm 2)$ to serve as bias correction for known leading (NNLL) bottom quark mass effect in γ_{ζ}^q :

$$\Delta\gamma_{\zeta}^q(b_T, m_b, \mu) = \frac{\alpha_s^2}{\pi^2} C_F T_F (m_b b_T)^2 \left(\ln \frac{b_T^2 m_b^2}{4e^{-2\gamma_E}} - 1 \right) \approx -(0.25 \text{ GeV})^2 b_T^2$$

Nonperturbative model for the TMD PDF = $B_i(x, b_T, \mu, \nu/\omega) \sqrt{S(b_T, \mu, \nu)}$

- Most general structure of leading NP correction $b_T^2 \Lambda_i^{(2)}(\mathbf{x})$ is complicated
- However, can show that for a given process and fiducial volume, only a *single average coefficient* $\bar{\Lambda}$ remains after the integral over hard phase space Φ_B :

[Ebert, JKLM, Stewart, Sun '22]

$$\tilde{\sigma}(b_T) = \tilde{\sigma}^{(0)}(b_T) \left\{ 1 + b_T^2 \left(2\bar{\Lambda}^{(2)} + \gamma_{\zeta,q}^{(2)} L_{Q^2} \right) \right\} + \mathcal{O}[(\Lambda_{\text{QCD}} b_T)^4]$$

$$\bar{\Lambda}^{(2)} = \frac{\int d\Phi_B A(\Phi_B) \sum_{i,j} \sigma_{ij}^B(Q) f_i^{(0)}(x_a, \mu_0) f_j^{(0)}(x_b, \mu_0) [\Lambda_i^{(2)}(x_a) + \Lambda_j^{(2)}(x_b)]}{2 \int d\Phi_B A(\Phi_B) \sum_{i,j} \sigma_{ij}^B(Q) f_i^{(0)}(x_a, \mu_0) f_j^{(0)}(x_b, \mu_0)}$$

- Idea: Promote $\bar{\Lambda}^{(2)}$ to a single-parameter Gaussian model

$$f_i^{\text{NP}}(x, b_T) = \exp(-\Omega^2 b_T^2) \quad \text{with} \quad \bar{\Lambda}^{(2)} = -\Omega^2$$

- Take central $\Omega = 0.5 \text{ GeV}$ and vary it as $\Omega = \{0, 0.7\} \text{ GeV}$
- For $q_T \gg \Lambda_{\text{QCD}}$, this captures the most general form of the leading NP correction to the rapidity-integrated q_T spectrum

- Use exact analytic solutions of virtuality and rapidity RG equation, combined with fast numerically exact solution of β function [Ebert '21]

► Eliminates source of truncation error at fraction of cost of full Runge-Kutta

- Choose RG boundary scales as *hybrid profile scales* $\mu_X(b_T, q_T, Q)$:

[Lustermans, JKLM, Tackmann, Waalewijn '19]

$$\mu_X(b_T, q_T \ll Q) = \frac{b_0}{b_T} \quad \text{but} \quad \mu_X(b_T, q_T \rightarrow Q) \rightarrow \mu_{\text{FO}} = Q$$

- Apply “local” b^* prescription starting at $\mathcal{O}(b_T^4)$ to virtuality scales *only*:

$$\mu_X \rightarrow \mu_X^* = \left[(\mu_X^{\min})^4 + \left(\frac{b_0}{b_T} \right)^4 \right]^{1/4} = \frac{b_0}{b_T} \left\{ 1 + \mathcal{O} \left[(\mu_i^{\min} b_T)^4 \right] \right\}$$

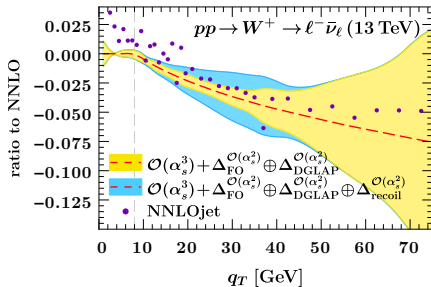

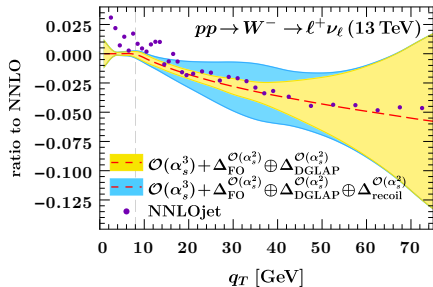

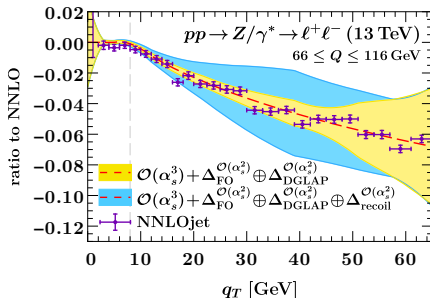

► Avoids contaminating nonperturbative corrections at quadratic order

[Conflict with b_T -space renormalon structure: Scimemi, Vladimirov '18]

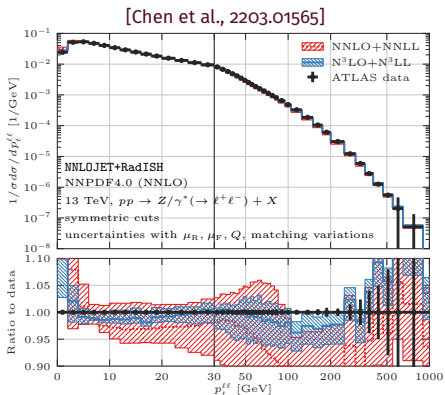

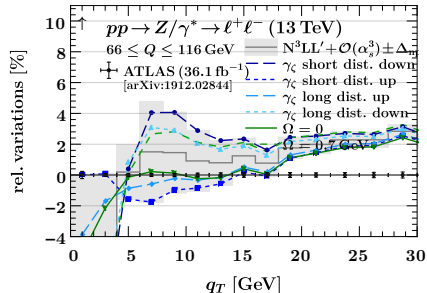

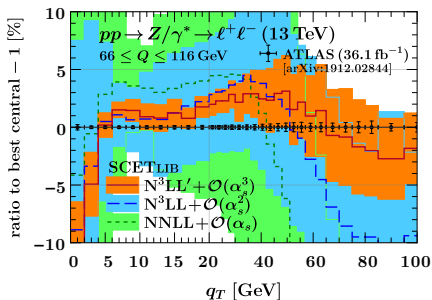

[Translation back to momentum space: Ebert, JKLM, Stewart, Sun '22]

- For PDFs inside beam functions, use $\mu_f^{\min} = \min\{Q_0, m_c\}$

$\mathcal{O}(\alpha_s^3)$ nonsingular interpolations

Comparison with RadISH (using identical NNLOjet fixed-order matching)

- Can recover the data for $q_T \leq 4$ GeV with NP model \approx off
- To recover the RadISH result at ≤ 4 GeV, would need large **positive** $\gamma_\gamma^{(2)}$ or $\bar{\Lambda}^{(2)}$
- In either case, cannot recover ≥ 20 GeV due to $\Lambda_{\text{QCD}}^2/q_T^2$ scaling imposed by TMD factorization & OPE

Comparison with RadISH (using identical NNLOjet fixed-order matching)

- Common ingredient: Sudakov evolution kernels from $\mu_0 \sim Q$ to $\mu \sim 1/b_T, q_T$

e.g.:
$$K_\Gamma(\mu_0, \mu) = \int_{\mu_0}^{\mu} \frac{d\mu'}{\mu'} \Gamma[\alpha_s(\mu')] \ln \frac{\mu'}{\mu_0}$$

- Implementation of Sudakov kernels in SCETlib is exactly equal to numerical solution of β function + numerical μ' integral
 - ▶ $\beta(\alpha_s)$ and $\Gamma(\alpha_s)$ truncated after α_s^4 ,
no additional approximations or assumptions
 - ▶ Exact RGE closure $U(\mu_0, \mu) U(\mu, \mu_0) = 1$
 - ▶ Exact path independence in (μ, ν) or (μ, ζ) plane
- ...but much faster, thanks to closed-form results in [Ebert, 2110.11360] in terms of a single polynomial root-finding problem

Comparison with RadISH (using identical NNLOjet fixed-order matching)

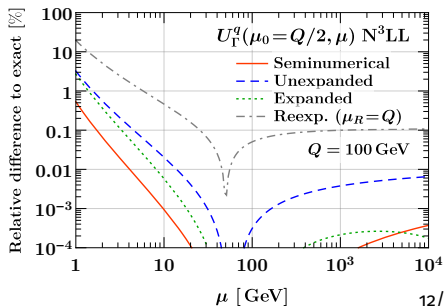

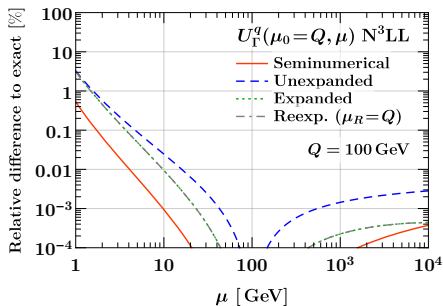

- Common ingredient: Sudakov evolution kernels from $\mu_0 \sim Q$ to $\mu \sim 1/b_T, q_T$

e.g.:
$$K_\Gamma(\mu_0, \mu) = \int_{\mu_0}^{\mu} \frac{d\mu'}{\mu'} \Gamma[\alpha_s(\mu')] \ln \frac{\mu'}{\mu_0}$$

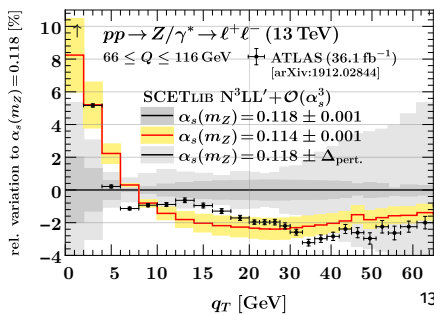

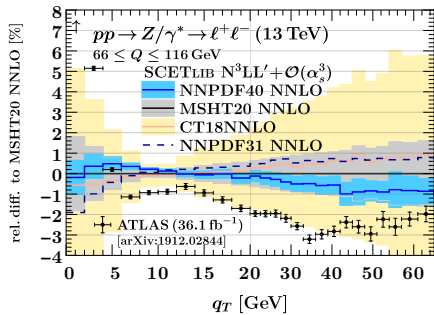

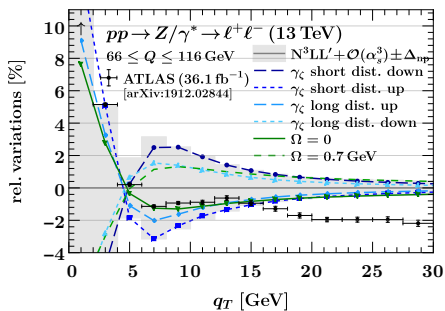

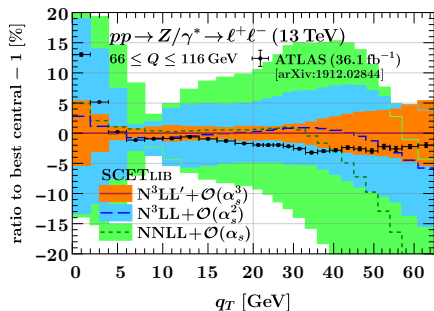

- Common to expand $K_\Gamma(\mu_0, \mu)$ in terms of $\alpha_s(\mu_0)$ throughout instead
 \Rightarrow simpler analytic solution with $g^{(1)}$ a function of an $\mathcal{O}(1)$ argument:

$$K_\Gamma^{\text{exp.}}(\mu_0, \mu) = L g^{(1)}(\alpha_s(\mu_0)L) + \text{NLL}, \quad L = \ln \frac{\mu_0}{\mu}$$

- However, reexpanding in terms of $\alpha_s(\mu_R)$, $\mu_R \neq \mu_0$ (read: μ_0 = resummation scale) leads to large truncation errors [Billis, Tackmann, Talbert, 1907.02971]

ATLAS normalized spectrum (Born leptons)

CMS normalized spectrum (dressed leptons)
