Ridge Structure from Color Glass Condensate Approach

2. Near Side and Away Side Azimuthal Correlation.

Two partons scatter off the same color domain of the nucleus receive similar transverse momentum kicks

\[ |q_1| \sim |q_2| \gg |k_1|, |k_2| \]

A simplified fixed-configuration picture

Nucleus with Gluon Saturation.
Typical color domain size \(1/Q_s\)

There are also quantum correlations from projectile wave function;
Assuming the two partons from the projectile are uncorrelated in this talk.

We are interested in Bose Correlation in the Target!

In dilute target limit (AKA two-gluon exchange approximation)

\[
\frac{dN}{d^2p_1d^2p_2} = \int_{q_1,q_2} \tilde{F}(p_1,q_1)\tilde{F}(p_2,q_2) \left( 1 + \frac{(2\pi)^2}{(N_c^2 - 1)S_\perp} \left[ \delta(q_1 + q_2) + \delta(q_1 - q_2) \right] \right)
\]

Bose correlation \(\longrightarrow\) near-side ridge

Not HBT!

\[
\frac{dN}{d^2p_1d^2p_2} \sim \delta(p_1 + p_2) + \delta(p_1 - p_2)
\]
1. In Color Glass Condensate framework, the fundamental degrees of freedom are the color charge densities \( \rho^a(x^-, x_\perp) \).

2. In McLerran-Venugopalan model, the color charge densities are assumed to follow Gaussian distribution.

\[
\left< \rho^a(x^-, x_\perp) \rho^b(y^-, y_\perp) \right> = \delta^{ab} \delta(x^- - y^-) \delta^{(2)}(x - y) g^2 \mu^2 (x^-, x_\perp)
\]

\[
\left< \rho^a(x) \rho^b(y) \rho^c(u) \rho^d(v) \right> = \left< \rho^a(x) \rho^c(u) \right> \left< \rho^b(y) \rho^d(v) \right> + \left< \rho^a(x) \rho^b(y) \right> \left< \rho^c(u) \rho^d(v) \right> + \left< \rho^a(x) \rho^d(v) \right> \left< \rho^b(y) \rho^c(u) \right>
\]

\[
\frac{dN}{d^2p_1 d^2p_2} = \int_{q_1, q_2} \tilde{F}(p_1, q_1) \tilde{F}(p_2, q_2) \left[ 1 + \frac{(2\pi)^2}{(N_c^2 - 1) S_\perp} \left[ \delta(q_1 + q_2) + \delta(q_1 - q_2) \right] \right]
\]
**Multi-Parton Correlations in Nuclear Wavefunction**

Proton/Nucleus is a many-parton system, how to probe multi-parton correlations in the nuclear wavefunction?

Form Factors

Event rate: Four-Jet/ Dijet \( \lesssim 0.05 \% \) with jet \( p_t > 5 \) GeV

Four jets production through two hard processes to probe two-parton GPD:

\[ \gamma + p/A \rightarrow c + \bar{c} + g_1 + g_2 + X \]

B. Blok and M. Strikman, EPJC (2014)

\[ \gamma + p/A \rightarrow c + \bar{c} + g_1 + g_2 + X \]

Figure from INT Program INT–17–3
Trijet Production in Deep Inelastic Scattering

Goal: find some observable that is
1. Sensitive to two particle correlation in the nuclear wave function

\[ \gamma^* + p/A \rightarrow q + \bar{q} + g + X \]

(a) Quark and antiquark are in color singlet state and locate in the forward rapidity region;
(b) The gluon jet locates in the central rapidity region.

Trijet production under two-gluon exchange

Transverse Momentum Conservation
\[ k' + k + p_1 + p_2 = 0 \]

Notation: \( p \equiv p_1 + p_2 + p_3 \), \( \Delta \equiv p_1 + p_2 \).

For phase space region
\[ |k'| \ll |p_3| \]
\[ p + k \sim p_3, \quad -k \sim \Delta \]
Diffractive Quark Antiquark Dijet + Gluon Jet in DIS

\[ \frac{d^3 N}{d^3 p_1 d^3 p_2 d^3 p_3} = \sum_{\alpha_1, \alpha_2, \alpha_3} \langle \psi_F | \hat{d}_{\alpha_1}^\dagger(p_1) \hat{d}_{\alpha_1}(p_1) \hat{b}_{\alpha_2}(p_2) \hat{b}_{\alpha_2}^\dagger(p_2) \hat{a}_{\alpha_3}(p_3) \hat{a}_{\alpha_3}^\dagger(p_3) | \psi_F \rangle \]

Final state wavefunction

\[ | \psi_F \rangle = \hat{C}^\dagger \hat{S} \hat{C} | \gamma^* \rangle \otimes | N \rangle. \]

Coherent operator (Soft gluon radiation operator)

\[ \hat{C} = \exp \left\{ i \int d^2 x \ b_i^q(x) \int_{\Lambda^-}^{\Lambda^+} \frac{dk^-}{2\pi |k^-|} (\hat{a}_i^{q\dagger}(k^-, x) + \hat{a}_i^{q}(k^-, x)) \right\} \]

S-Matrix operator

\[ \hat{S} = \exp \left\{ i \int d^2 x \ j(x) \ \alpha_T(x) \right\}. \]

Virtual Photon Fock Space Approximation

\[ | \gamma^* \rangle \simeq \sum_{q\bar{q}} \Psi_{q\bar{q}} | q\bar{q} \rangle \]

Test NLO QCD and measure \( \alpha_s \), single particle PDF

H1 Collaboration, PLB (2001)

Trijet and small-x in the literature:

A. Kovner and U. A. Wiedemann, PRD (2001)

Final state wavefunction

Coherent operator (Soft gluon radiation operator)

Virtual Photon Fock Space Approximation
The Two-Gluon Exchange Approximation (Dilute Limit)

\[ \frac{d^3N}{d^3p_1d^3p_2d^3p_3} = \left| M_{\text{diff}}(p_1, p_2, p_3) \right|^2 \]

At least two gluons have to be exchanged for the quark + antiquark to be in a color singlet state.

\[ M_{\text{diff}}(p_1, p_2, p_3) = g^3 \sqrt{2\pi T_{ab}^c} \int \frac{d^2k}{(2\pi)^2} \alpha_T^a(p + k) \alpha_T^b(-k) \frac{L_j}{- (p_1 + p_2 + k)} \psi^D_{\sigma_1\sigma_2}(p_1, p_2, k) \]

\[ \psi^D_{\sigma_1\sigma_2}(p_1, p_2, k) = \left[ \psi_{\sigma_1\sigma_2}(p_1^+, p_1^-; p_2^+, p_2^-; p_3); k - p_1 + k - p_2 + k) - \psi_{\sigma_1\sigma_2}(p_1^+, p_1^-; p_2^+, p_2^-; p_3) + \psi_{\sigma_1\sigma_2}(p_1^+, p_1^-; p_2^+, p_2^-; k) \right] \]

Four different ways of attaching two gluon lines to quark and antiquark.
The Two-Gluon Exchange Approximation (Dilute Limit)

\[
\frac{d^3N}{d^3p_1 d^3p_2 d^3p_3} = -(2\pi)^6 \int \frac{d^2k}{(2\pi)^2} \frac{d^2l}{(2\pi)^2} L_2(- (p_1 + p_2 + k), p_3) L_2(- (p_1 + p_2 + l), p_3) \left[ \psi_{\sigma_1,\sigma_2}(p_1, p_2, k) \psi_{\sigma_1,\sigma_2}^*(p_1, p_2, l) \right] \\
\times T_{ab}^{\gamma_3} T_{cd}^{\gamma_3} \left\langle \alpha^a_T(p + k) \alpha^b_T(-k) \alpha^c_T(-p - l) \alpha^d_T(l) \right\rangle
\]

Only two non vanishing contractions of color charge densities due to the color singlet state requirement for the quark and the antiquark.

\[
T_{ab}^{\gamma_3} T_{cd}^{\gamma_3} \left\langle \rho^a_T(p + k) \rho^b_T(-k) \rho^c_T(-p - l) \rho^d_T(l) \right\rangle = -N_c(N_c^2 - 1) g^4 \mu_\perp^4 S_\perp \left[ (2\pi)^2 \delta^{(2)}(k - l) - (2\pi)^2 \delta^{(2)}(p + k + l) \right]
\]

Dijet and Gluon jet uncorrelated production

Dijet and Gluon jet near-side ridge correlation

Opposite sign and no color or area suppressions.
Beyond the Correlation Limit: Charge Neutrality of Dipole Wavefunction

\[
\frac{d^3N}{d^3p_1 d^3p_2 d^3p_3} = -(2\pi)^6 \left( \frac{d^2k}{(2\pi)^2} \frac{d^2l}{(2\pi)^2} \right) L_j \left[ \psi^{D*}_{i\sigma_2}(p_1, p_2, k) \psi^{D}_{i\sigma_1}(p_1, p_2, l) \right] \times T^{a_b}_{c_d} \left\{ \alpha^a_f(p + k) \alpha^b_f(-k) \alpha^c_f(-p - l) \alpha^d_f(l) \right\}
\]

The part containing dipole wave function vanishes when

\[
k = 0 \text{ or } -k' = k + p_1 + p_2 = 0.
\]

Or physically speaking \( |k'|, |k| \ll |p_1| \sim |p_2| \sim Q\)

The CORRELATION LIMIT

The exchanged gluon has much smaller momentum, thus cannot resolve the finer structure of the dipole.

Size of gluon probe \(\gg\) Size of quark-antiquark dipole \(\sim 1/Q\)
Event Selection

The trijet production depends on three external momenta $p_1, p_2, p_3$. These six variables characterize all the possible trijet events. We explore events $p_3 \approx \Delta = p_1 + p_2$ to see if there are enhancement.

The correlation limit: $|P_\perp| \gg |\Delta|$ with $P_\perp = \frac{1}{2}(p_1 - p_2)$.

To go beyond the correlation limit, simply specify $|p_1| \gg |p_2|$. Do not integrate over $|p_1|, |p_2|$.

\[
C(|p_3|, |\Delta|, \theta; |p_1|, |p_2|) \equiv \frac{1}{N} \int d\beta_3 \frac{d^3N}{d^3p_1d^3p_2d^3p_3},
\]

\[
\cos \theta = \frac{p_3 \cdot \Delta}{|p_3||\Delta|}, \quad \beta_3 : \text{azimuthal angle of } p_3.
\]
Numerical Results: Zero-Angle Peak

The zero-angle peak at $|p_3| = |\Delta|$ is the salient feature of Bose correlation.

Input parameters:

- $|p_3| = |\Delta| = 10 \text{ GeV}$; $|p_1| = 10 \text{ GeV}$
- Photon virtuality: $Q = 1 \text{ GeV}$
- Gluon saturation scale: $Q_s = 2 \text{ GeV}$
- Azimuthal Angle Range: $-\pi/4 < \theta < \pi/4$

One can vary values of $|p_3| = |\Delta|$ from 5 GeV − 15 GeV, as well of varying the corresponding values of $|p_1|$, $|p_2|$ as long as $|p_1| \gg |p_2|$, the zero-angle peaks persist.
Zero-Angle Peak Comes from Gluon Bose Correlation

The zero-angle peak mainly comes from the momentum region $|k| \sim |\Delta|$, in this situation, $-k \approx \Delta, p + k \approx p_3$, corresponding to the Bose correlation of the two gluons from the target.

Note that the other possibility $k \approx \Delta$ is extremely unlikely as then $|k'| \approx 2|\Delta| \gg Q$, a quark (or antiquark) with momentum of magnitude $Q$ cannot radiate a gluon whose momentum is $k'$.

Input parameters:

$|p_3| = |\Delta| = 10 \text{ GeV}; |p_1| = 10 \text{ GeV};$

Photon virtuality: $Q = 1 \text{ GeV};$

Gluon saturation scale: $Q_s = 2 \text{ GeV}$

Azimuthal Angle Range: $-\pi/4 < \theta < \pi/4$
Numerical Results: Dependence on Gluon Saturation Scale

Bose enhancement peaks become more prominent with increasing gluon saturation scale.

\[
\langle \rho^a(k)\rho^b(l) \rangle = \delta^{ab} g^2 \mu^2 \frac{k^2}{k^2 + Q_s^2} \delta^{(2)}(k + l)
\]

Summary and Outlook

• We proposed and demonstrated that diffractive quark antiquark dijet + gluon jet production in DIS has near-side ridge correlation which originates from the Bose correlations in the nuclear wave function.

• The correlation signals are prominent for events outside the conventional correlation limit.

• The correlation signals are more prominent for nuclear target that has larger saturation scale.

• The numerical computations are done in the two-gluon exchange approximation (dilute limit). It would be very interesting, although challenging, to analyze the general case of dense nuclear target.
Input parameters:

\[ |p_3| = |\Delta| = 6 \text{ GeV}; \quad |p_1| = 8 \text{ GeV}; \]

Photon virtuality: \( Q = 1 \text{ GeV}; \)

Gluon saturation scale: \( Q_s = 2 \text{ GeV} \)

Azimuthal Angle Range: \(-\pi/4 < \theta < \pi/4\)
