M. Giovannozzi, P. Hagen, M. Lamont, G. Montenero, V. Remondino,
S. Redaelli, F. Schmidt, R. Steinhausen, M. Strzelczyk, R. Tomas, E. Todesco,
W. Venturini Delsolaro, J. Wenninger, L. Walckiers

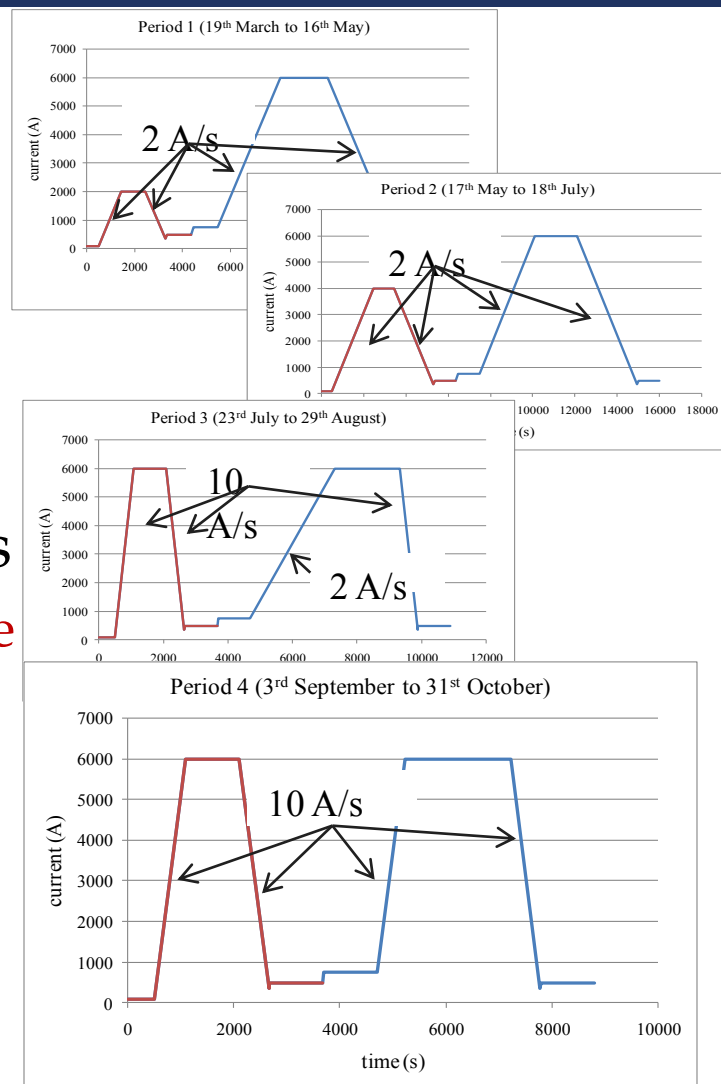

CONTENTS

- Precycle
 - How many types we had?
 - Has it been followed? Can we made it shorter ?
- Chromaticity
 - Decay at injection – how to include ?
 - During ramp – can be improved ?
- Tune
 - Decay at injection
- Hysteresis issue

HOW DID WE PRECYCLE THE LHC ?

- Four combinations of precycle and cycle ramp rates and currents
 - We **started rather far from nominal**
 - No experience on decay and snapback in this regime
 - 2 A/s never explored in SM18
- Since September 3 we are at 10 A/s
 - With **same parameters for physics cycle and precycle**
- What still missing w.r.t. nominal
 - The energy ... still at 6 kA
 - This should give smaller decay and snapback (about 1/2)

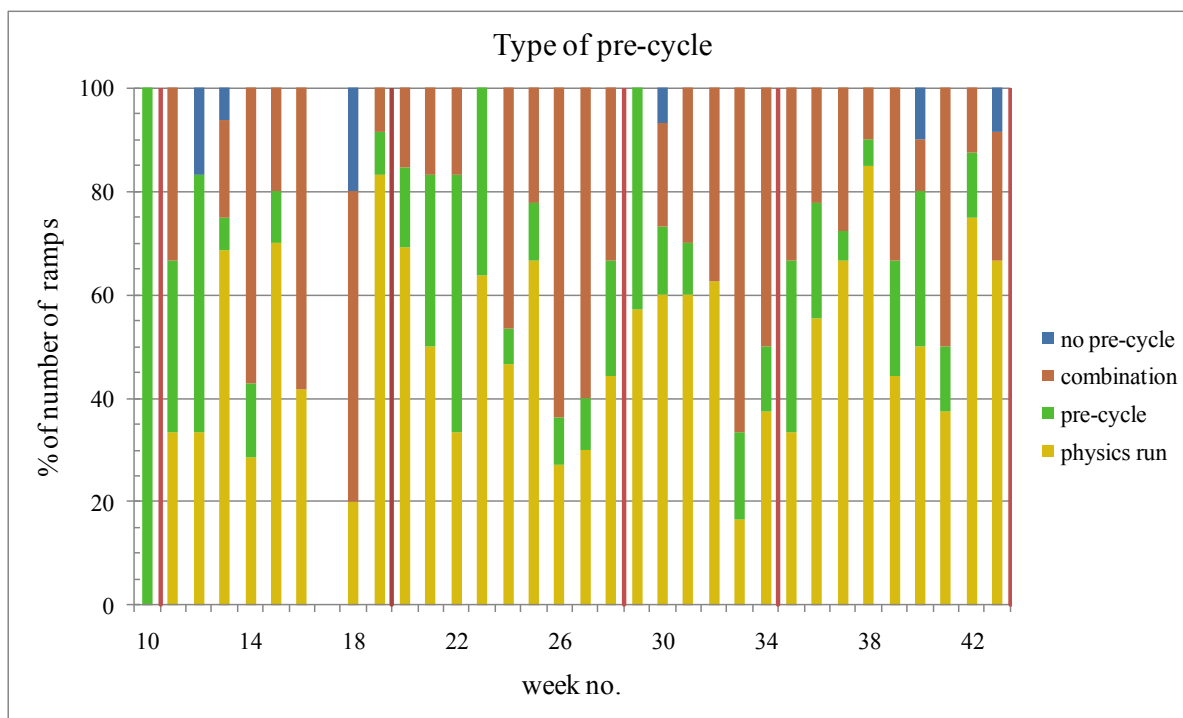

Combination of ramp and precycles in 2010 [N. Aquilina]

HOW DID WE PRECYCLE THE LHC ?

- The LHC from the first day of operations uses the previous physics run as a pre-cycle!
 - If the physics run terminates abnormally one has to pre-cycle
 - Procedure followed at 97% in 2010 😊😊

Pre-cycle type in 2010 for all ramps [N. Aquilina]

HOW DID WE PRECYCLE THE LHC ?

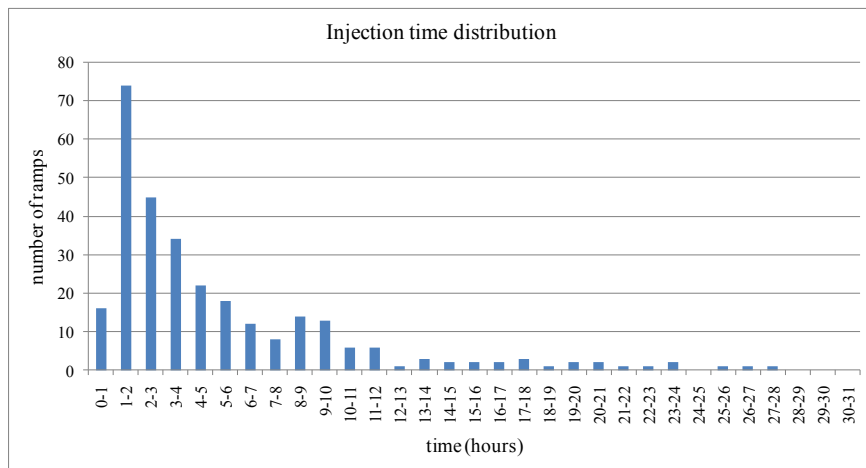

- The LHC from the first day of operations uses the previous physics run as a precycle!
 - 54% of the ramps used previous physics cycle 😊😊
 - Precycle takes 90 minutes
 - In average 45 minutes/ramp spent to precycle
 - At this stage of operation is **not dominant in the turn around time**
- Anyway, it could be improved
 - Dominated by the MQM MQY – one could study possibilities to make it shorter
- Other comments
 - Special ramp-down when an access will be given (to avoid ramping up dipoles)
 - If a circuit trips, can we ignore it? General receipt is in CERN-ATS-2010-174 <http://cdsweb.cern.ch/record/1283477/files/CERN-ATS-2010-174.pdf>

CONTENTS

- Precycle
 - How many types we had?
 - Has it been followed? Can we made it shorter ?
- Chromaticity
 - Decay at injection – how to include ?
 - During ramp – can be improved ?
- Tune
 - Decay at injection
- Hysteresis issue

- How long we usually stay at injection?
 - At least 30 minutes, in general 1-2 h, in average 5 h

Time at injection for all ramps in 2010 [N. Aquilina]

Decay of b_3 over 10000 s in 20 cases [N. Aquilina, L. Deniau, N. Sammut]

- Measurements at SM18 showed that **after 30 minutes most of the b_3 decay is ended (at 50 A/s ramp rate)**
- Therefore we decided **to correct the full decay via static trims** thinking that in 2010 we always inject when decay is ended
- The option has been anyway coded and is available [M. Strzelczyk]

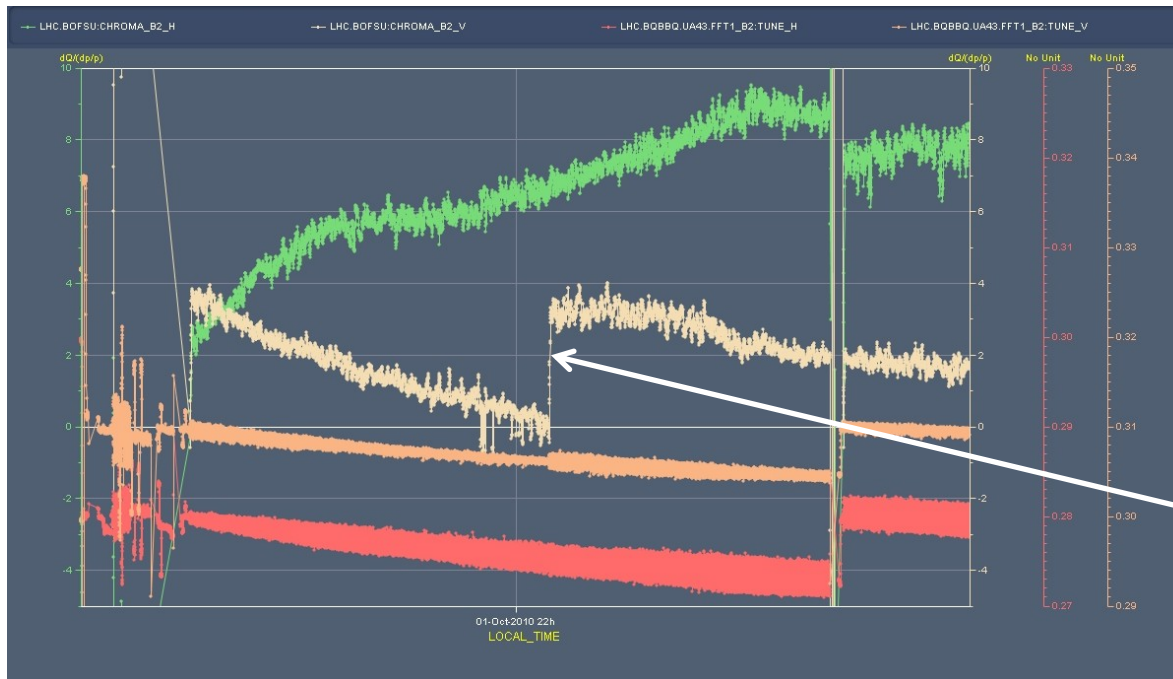

- Beam measurements show decay on longer times
 - The size of decay is in agreement with FiDeL (~ 0.5 units b_3 , i.e., 20-25 units of chromaticity – but **in the LHC is much slower!**)

Chromaticity versus time at injection, beam1 (blue), beam2 (red) [W. Venturini Delsolaro]

- In 2010 variability in injection time **changes chromaticity of 10-15**
- Since trims of the previous injection are kept, one can inject on negative chromaticity and lose the beam

- Measurements from M. Pojer
 - Continuous measurements of chromaticity during injection (1 h)
 - About 4 units in 1 h – this after 1 h at injection
 - Compatible with previous measurements

Here chromaticity has been trimmed up by 4 units

Chromaticity versus time at injection, horizontal (green), vertical (beige) [M. Pojer]

CHROMATICITY DECAY AT INJECTION

- How the EIC cope with this?
 - **Manual trim based on experience** – no general strategy
 - The trim is on the lattice sextupoles (MSF/D) whereas it should go on the MCS
- Solution for 2011
 - Use the **process to correct decay** at injection through MCS already prepared [M. Strzelczyk]
 - But **change the FiDeL time constant** according to beam measurements and
 - **Measure periodically decay** at injection in 2011
 - Measure decay in dipoles with 10 A/s and 6 kA for 10 h? But on one dipole probably this is not enough

CHROMATICITY DURING RAMP

- We have ~6 measurements of chromaticity during ramp [R. Steinhagen]

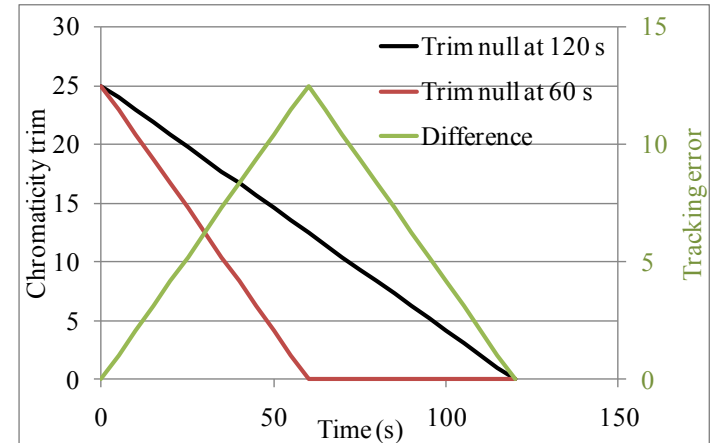

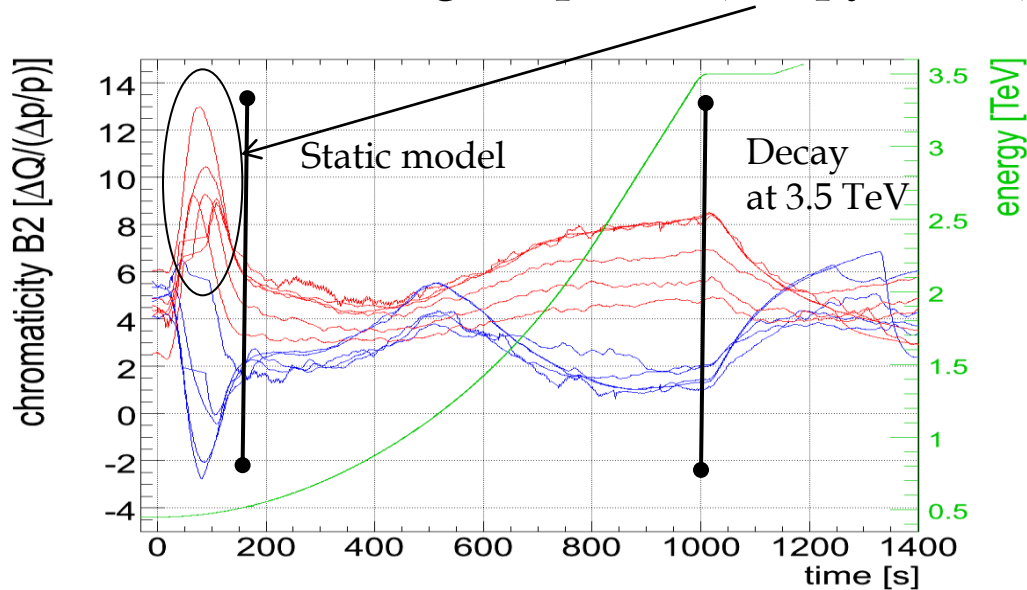

Chromaticity during the 10 A/s ramps , 6 cases blue: horizontal - red: vertical [R. Steinhagen]

- FiDeL error **during snapback: ± 7 units** – chromaticity is negative ☹
- FiDeL error after snapback **during ramp: ± 3 units** – difficult to do better
- **Decay at 3.5 TeV: 7 units**
- Tracking precision is sufficient for operation – but it could be improved in the snapback part

CHROMATICITY DURING RAMP

- Error during snapback (the pyramid): two possible causes

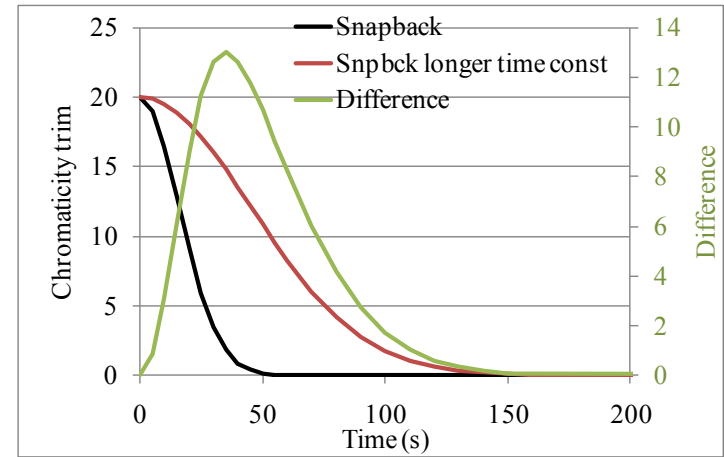

- Trim at injection decreases linearly with time up to 120 s
- If this **trim vanishes too rapidly** this can create the pyramid

CHROMATICITY DURING RAMP

- Error during snapback (the pyramid): two possible causes

- If the **snapback time constant** is wrong one also gets a pyramid
- But it should be much, much longer ... (factor 5-10)

 - Has it been followed? Can we made it shorter ?
- Chromaticity
 - Decay at injection – how to include ?
 - During ramp – can be improved ?
- Tune
 - Decay at injection
- Hysteresis issue

- There is evidence of **tune decay at injection**

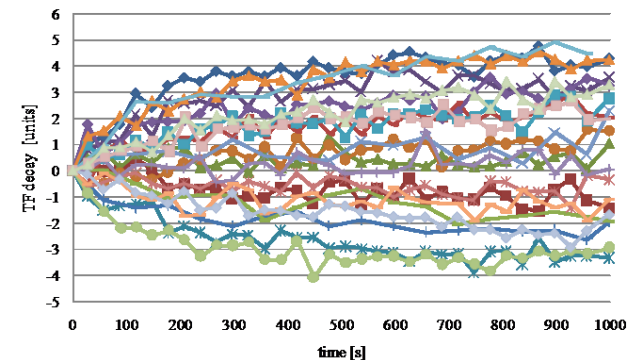

Decay of tune at injection on 1st Oct 2010 [M. Pojer]

Decay of tune at injection in Tevatron [G. Annala, et al.]

- About **0.005 over 1 h** soon after precycle
 - As far as I understand not an issue
 - But **it could be included**
- Origin: could be decay in the quadrupoles
 - $0.005/60 = 1.2$ unit – compatible with meas.

Decay of MQ transfer function [L. Deniau]

CONTENTS

- Precycle

- Hysteresis issue

Psycho, 50 years celebration
[A. Hitchcock]

- Hysteresis is a ghost which is periodically hunting our nights ... since years

- Two issues:

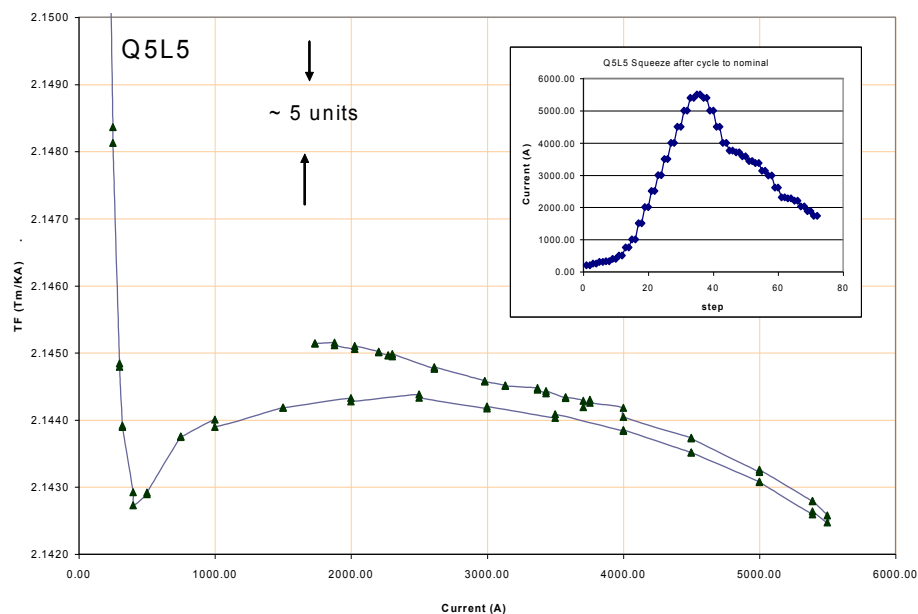

- IR quads during squeeze, having current ramping down

- Correctors, which are trimmed down and up by EiC and feedback

- Implemented strategy

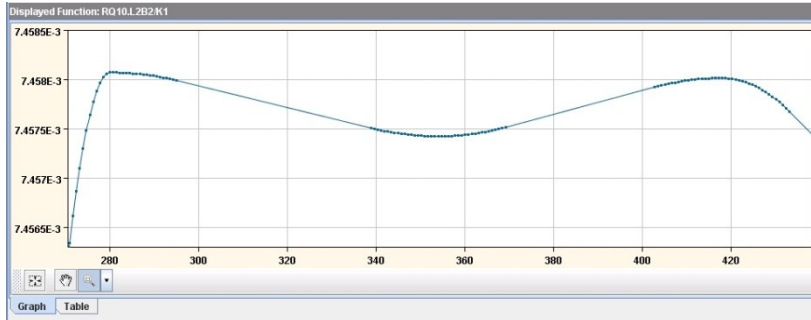

- When the $dI/dt < 0$ the model automatically changes hysteresis branch [M. Strzelczyk]

- With smoothing needed for not tripping the power converters and QPS

Measured transfer function during squeeze [W. Venturini Delsolaro]

● Problems - 1

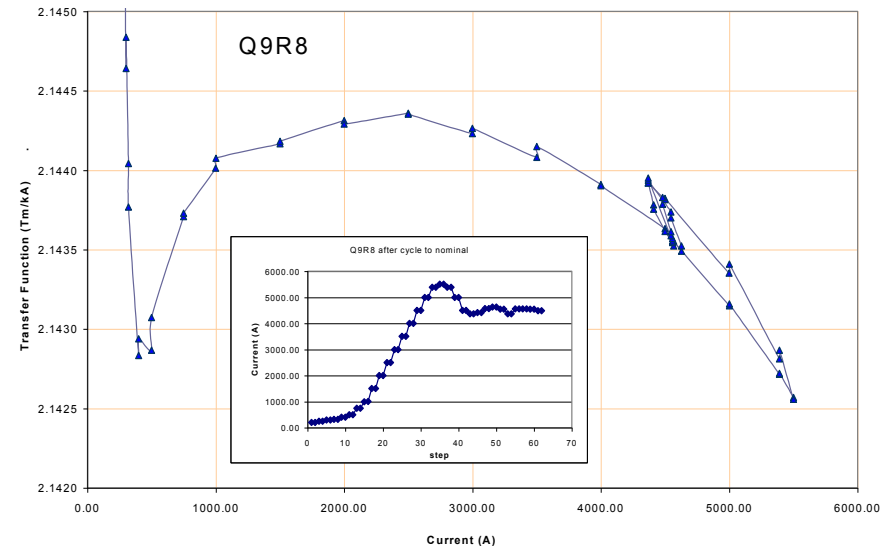

Required gradient during squeeze [M. Strzelczyk]

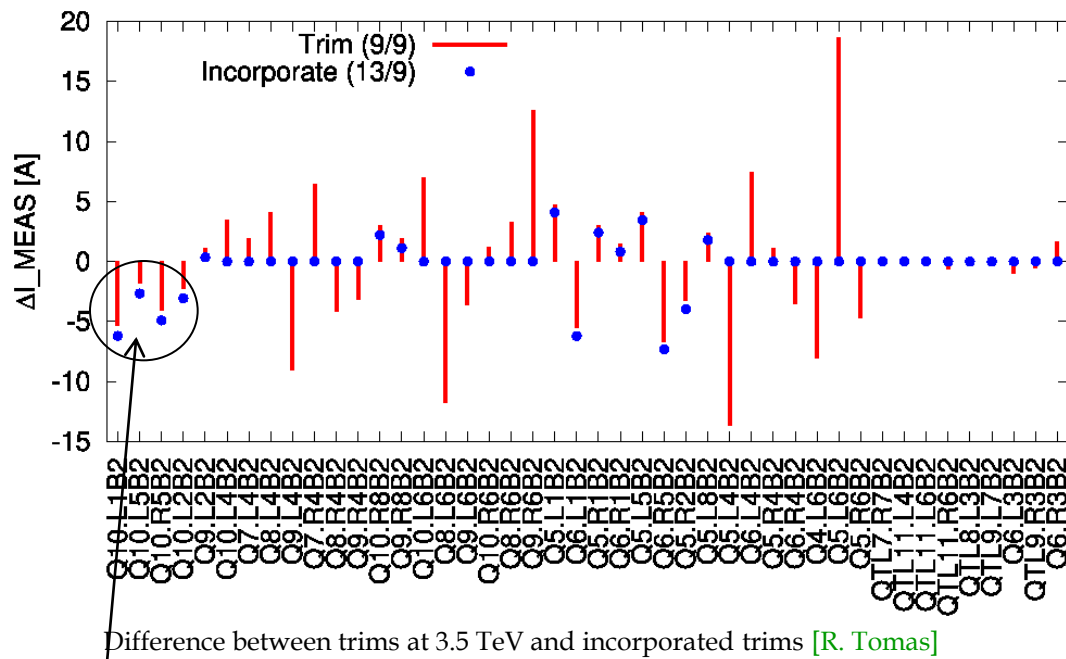

Corresponding current in PC [M. Strzelczyk]

- For small changes of currents, one has **jumps** whereas the magnet in reality stays on the **same branch**
- Not nice, not necessary, and can induce beam losses [X. Buffat]

Measured transfer function during squeeze [W. Venturini Delsolaro]

- Problems - 2

- When trims are first tried on actual settings and then incorporated, the branching causes a **small difference** – seen for beta beating correction
- This gives negligible effects on beta beating, but it is not nice

- Estimates show that in squeeze the **impact of hysteresis is small**

Error in units due to neglecting hysteresis during squeeze [P. Hagen]

- Going to 1.1 m becomes important (10-50 units) in a few cases which are well known a priori (mainly MQM) – if neglected this gives 10% beta beating
- No evidence of problems related to hysteresis, neither in correctors nor during squeeze
 - We **propose to remove it** – we will include as trim for the few magnets that need it, and for β^* that needs it

CONCLUSIONS

- Precycling
 - Is **correctly followed** – 50% of times previous physics cycle is used
- Decay of chromaticity
 - ~20 units of decay, as expected by FiDeL, but on **much longer times**
 - It is **an issue for operation** – should now be included
 - It will be in 2011, **parameters based on beam measurements**
- Chromaticity during ramp
 - Tracked within ± 7 units – we can **improve the initial part**

CONCLUSIONS

- Tune decay
 - About 0.005 units, possibly due to MQ – could be automatically tracked
- Hysteresis
 - No evidence of problems related to hysteresis, neither in correctors nor during squeeze
 - Some side effects due to its implementation
 - We propose to remove it – we will include it only if really needed

ACKNOWLEDGEMENTS

- Thanks for discussions and comments
