Introduction

Standard Pulsar Model

- ▶ The large rotating magnetic field induces an electric field
- ▶ The induced electric field rips particles from the star's surface
- ▶ The last closed magnetic field lines touch the light cylinder at $R_{LC} = \frac{cP}{2\pi}$
- ▶ In the braking model the change in rotational energy is equated to the luminosity radiated by a magnetic dipole in a vacuum
- ▶ This may be written as the equation $\dot{\Omega} = -k\Omega^n$

Aims

Develop a new general emission model to work for a WD binary scenario:

- ▶ Solve particle dynamics generally without assuming super-relativistic particles and small pitch angles.
- ▶ Calculate the broadband light curves and spectra at different orbital phases.
- ▶ Calculate Stokes parameters, PPA, and degree of polarisation at different orbital phases.
- ▶ Calibrate our code with the millisecond pulsar emission code of Harding and collaborators.

Adaptive ODE Solver

- Solve Lorentz equation:

$$\frac{dp}{dt} = q \left(\mathbf{E} + \frac{c\mathbf{p} \times \mathbf{B}}{\sqrt{m^2 c^4 + \mathbf{p}^2 c^2}} \right). \quad (1)$$

- Do n-stage evaluations to solve the ODE depending on method accuracy.
- One can calculate the next value by weighing stages, $y_{n+1} = y_n + h \sum_{i=1}^s b_i k_i$.
- One can use a method with embedded lower order to get a truncation error, $\tau_{n+1} = y_{n+1} - y_{n+1}^* = \sum_{i=1}^s (b_i - b_i^*) k_i$.
- Calculate the adaptive next step size using τ_{n+1} and a given accuracy threshold.

$$\begin{aligned} k_1 &= f(t_n, y_n), \\ k_2 &= f(t_n + c_2 h, y_n + h(a_{21} k_1)), \\ k_3 &= f(t_n + c_3 h, y_n + h(a_{31} k_1 + a_{32} k_2)), \\ &\vdots \\ k_s &= f(t_n + c_s h, y_n + h(a_{s1} k_1 + a_{s2} k_2 + \dots + a_{s,s-1} k_{s-1})). \end{aligned}$$

$$\begin{array}{c|cccc} c_1 & a_{11} & a_{12} & \dots & a_{1s} \\ c_2 & a_{21} & a_{22} & \dots & a_{2s} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ c_s & a_{s1} & a_{s2} & \dots & a_{ss} \end{array} = \frac{\mathbf{c} \mid \mathbf{A}}{\mathbf{b}^T}$$

$$\begin{array}{cccc} b_1 & b_2 & \dots & b_s \\ b_1^* & b_2^* & \dots & b_s^* \end{array}$$

Calibration of ODE Solver

- Set $E = 0$.
- Conserved energy and constant pitch angle for:
 - Constant B-field.
 - Changing B-field strength.
- Conserved energy for static magnetic dipole and see if the obtained magnetic mirror effect as well as drift are correct.

$$\mathbf{v}_{\nabla B} = \frac{mv_{\perp}}{2eB} \frac{\mathbf{B} \times \nabla B}{B^2}.$$

Higher-Order ODE Schemes

Modelling the high-energy curvature radiation for the Vela pulsar using a general particle dynamics approach.

Louis Du Plessis

► The ODE schemes implemented in the code:

- Runge-Kutta Fehlberg 4(5): 5 stage.
- DVERK 6(5): 8 stage.
- Prince-Dormand 8(7): 12 stage.
- Adaptive Curtis 10(8): 18 stage.
- Adaptive Hiroshi 12(9): 29 stage.

► Benchmark of schemes:

Tol $1e^{-12}$	RKF	DV	PD	CR	HR
Time vs RKF	1	0.82	0.36	0.32	0.65
$\delta\gamma$	0.4	0.25	0.001	0.014	0

Tol $1e^{-14}$	RKF	DV	PD	CR	HR
Time vs RKF	1	0.82	0.29	0.23	0.48
$\delta\gamma$	0.01	0.008	0	0	0

Radiation-Reaction Force

- Use equation from Landau and Lifshitz for general radiation-reaction force:

$$\begin{aligned} \mathbf{f} = & \frac{2e^3\gamma}{3mc^3} \left\{ \left(\frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla \right) \mathbf{E} + \frac{1}{c} \mathbf{v} \times \left(\frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla \right) \mathbf{H} \right\} \\ & + \frac{2e^4}{3m^2c^4} \left\{ \mathbf{E} \times \mathbf{H} + \frac{1}{c} \mathbf{H} \times (\mathbf{H} \times \mathbf{v}) + \frac{1}{c} \mathbf{E} (\mathbf{v} \cdot \mathbf{E}) \right\} \\ & - \frac{2e^4\gamma^2}{3m^2c^5} \mathbf{v} \left\{ \left(\mathbf{E} + \frac{1}{c} \mathbf{v} \times \mathbf{H} \right)^2 - \frac{1}{c^2} (\mathbf{E} \cdot \mathbf{v})^2 \right\}. \end{aligned} \quad (3)$$

- The first term of Equation 3 requires 9, 18 or 36 evaluations of the B-field per stage to find the derivatives.
- This first term is $\sim 10^8 - 10^{10}$ times smaller than the largest component.
- The super-relativistic form of Equation 3 is given by:

$$f_x = -\frac{2e^4\gamma^2}{3m^2c^4} \left\{ (E_y - H_z)^2 + (E_z + H_y)^2 \right\} \quad (4)$$

- Equation 3 and 4 converge at a Lorentz factor around $10^4 - 10^5$.

$$\begin{aligned} P_{rad} &= \mathbf{F}_{rad} \cdot \mathbf{v}, \\ E_{rad} &= \int \mathbf{F}_{rad} \cdot \mathbf{v} \cdot dt \end{aligned} \quad (5)$$

Comparison with Takata et al. (2019)

- Takata uses rewritten forms of equations from Harding et al. (2005).

$$\frac{d\gamma}{dt} = -\frac{P_{\perp}^2}{t_s}$$

$$\frac{d}{dt} \left(\frac{P_{\perp}^2}{B} \right) = -2 \frac{B}{t_s \gamma} \left(\frac{P_{\perp}^2}{B} \right)^2 \quad (6)$$

- Where $t_s = 3m_e^3 c^5 / 2e^4 B^2$.
- They predict the mirror at $r_m \sim a \sin^{2/3} \theta_p$
- The super-relativistic case agrees with Takata's γ_{loss} but not the mirror point.
- The general case disagrees largely with Takata's results.

Emission Map Calculations

- ▶ We are only looking at curvature radiation for the calibration.
- ▶ We temporarily use the analytical formula for the static dipole curvature radius.
- ▶ The perpendicular E-field for a co-rotating plasma in the retarded-dipole scenario is given by:
- ▶ $\mathbf{E}_{\perp} = (-\boldsymbol{\Omega} \times \mathbf{r})/c \times \mathbf{B}$.
- ▶ The phase corrections are given by:
- ▶ $\phi_{obs} = \phi_{em} - \mathbf{r}_{em} \times \boldsymbol{\eta}_{em}/R_{LC} - \Delta\phi_{rot}$
- ▶ Drift velocity is calculated using:
- ▶ $\mathbf{v}/c = \mathbf{E} \times \mathbf{B}/B^2$.
- ▶ Figures from Barnard et al.(2021).

Curvature Radius Calculations

- ▶ The particle curvature radius can be calculated using:
- ▶ $\rho_c = \frac{1}{\sqrt{(x'')^2 + (y'')^2 + (z'')^2}}$.
- ▶ Using numerical differentiation we calculate x_i'' using:
- ▶ $x_i'' = (-3x'_{i-1} + 4x'_i - x'_{i+1})/2ds$.
- ▶ What difference does including the gyroradius have on the curvature radius?
- ▶ Use the effective curvature radius calculation employed in synchro-curvature radiation models.
