Summary

- Physical process
- Proper choice of the VHE primary spectrum
- CRPropa simulations for different IGMF settings
- Comparison between the simulated SEDs and lightcurve with Fermi/LAT

Summary of a TeV γ -ray's life absent any other process

Summary of a TeV γ -ray's life with an IGMF

Probing the “weakest” IGMF through pair echoes from GRBs

- Since the pairs are deviated, the cascade emission is also delayed (Neronov et al. 2009):

$$\lambda_B \gg D_e \quad T_{delay} \simeq 7 \times 10^5 (1 - \tau^{-1})(1 + z)^{-5} \left[\frac{E}{0.1 \text{ TeV}} \right]^{-5/2} \left[\frac{B}{10^{-18} \text{ G}} \right]^2 s$$

$$\lambda_B \ll D_e \quad T_{delay} \simeq 10^4 (1 - \tau^{-1})(1 + z)^{-2} \left[\frac{E}{0.1 \text{ TeV}} \right]^{-2} \left[\frac{B}{10^{-18} \text{ G}} \right]^2 \left[\frac{\lambda_{B0}}{1 \text{ kpc}} \right] s$$

$$F_{delay} \sim \frac{T}{T_{delay} + T} F_0$$

- The delayed emission is strongly diluted

“Delayed” cascade emission

Primary Spectrum

- Since the pairs are deviated, the cascade emission is also delayed (Neronov et al. 2009):

Acciari et al. 2019

$$\frac{dN}{dE} \propto \left(\frac{E}{0.4 \text{ TeV}} \right)^{-2.5 - 0.2 * \log(E/0.4 \text{ TeV})}$$

- We extrapolated the flux up to the first 6s after the prompt emission

CRPropa simulations

- Source:
 - Point source
 - $z=0.42$
 - Logparabola spectrum between 200 GeV and 10 TeV, 10^6 primary photons
 - Minimum energy of cascade photons: 0.05 GeV
- Magnetic Field:
 - Turbulent magnetic field with a Kolmogorov spectrum and different B_{rms}
 - Correlation length: $\gtrsim 1$ Mpc
- Observer:
 - Sphere with radius 1.6 Gpc with the source at the center

Starting time

- In order not to look for the echo emission in a time window where the GRB is still ongoing in the Fermi band we started counting the cascade photons from $T-T_0=2\times 10^4$ s

SEDs vs observation time: 15 days

SEDs vs observation time: 1 month

SEDs vs observation time: 3 months

SEDs vs observation time: 9 months

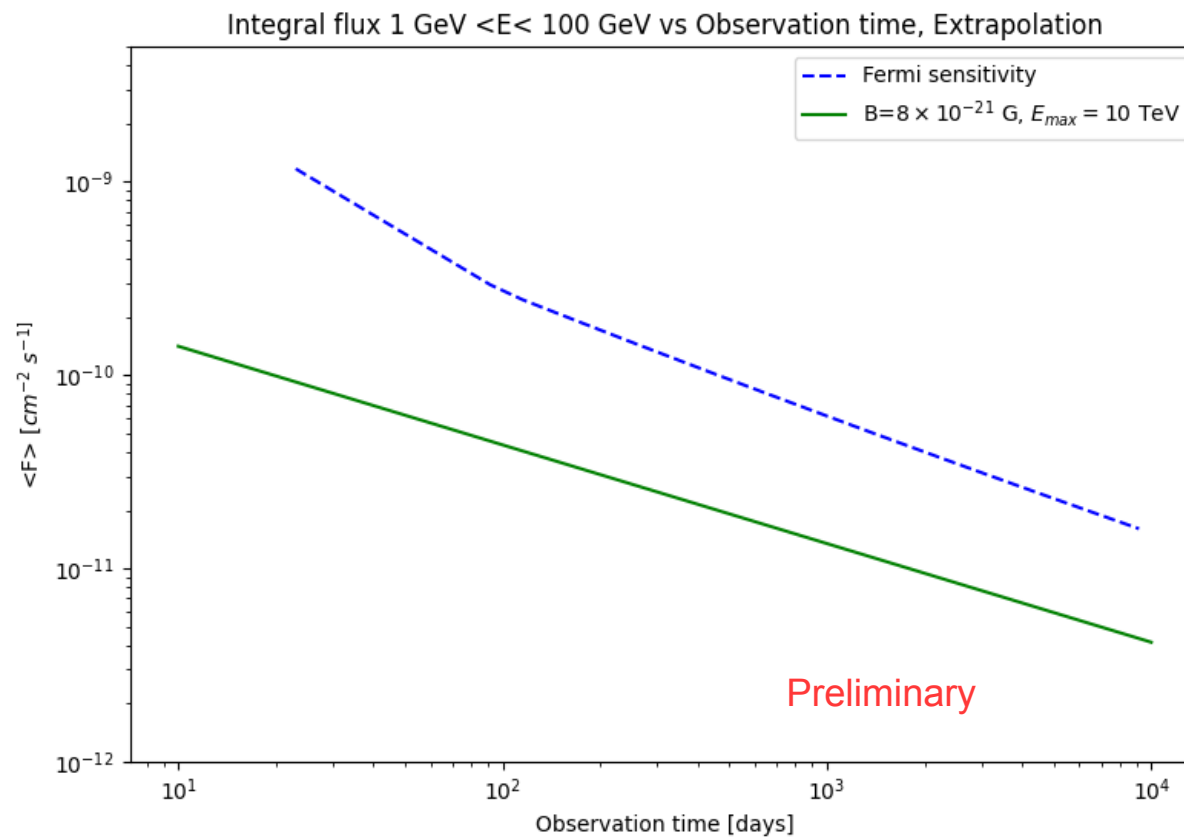

SEDs vs observation time: 24 months

Integral flux $1 \text{ GeV} < E < 100 \text{ GeV}$

Fermi/LAT sensitivity (95% CL)

Conclusions

- We simulated the cascade delayed emission from GRB 190114C for different IGMF settings and using, as VHE primary spectrum, the GRB model published by MAGIC coll.
- We performed the Fermi/LAT analysis from the end of the GRB up to 24 months
- Comparing the simulated SEDs and lightcurve with the Fermi/LAT limits no constraints can be placed on the IGMF strength
