Outline

1 Galactic pulsar population

2 Model

3 Results

4 Summary

1

Galactic pulsar population

Observations

- ~ 3000 pulsars detected in radio (Manchester et al. 2005).
 - Also bright in X-rays, optical and gamma-rays.
 - Over 250 gamma-ray pulsars discovered with Fermi-LAT (Abdo et al. (2013), Smith et al. (2019)).
- ➡ Statistical treatment of the γ -ray population in combination with deep radio surveys of the Galactic plane.

Pulsar population synthesis

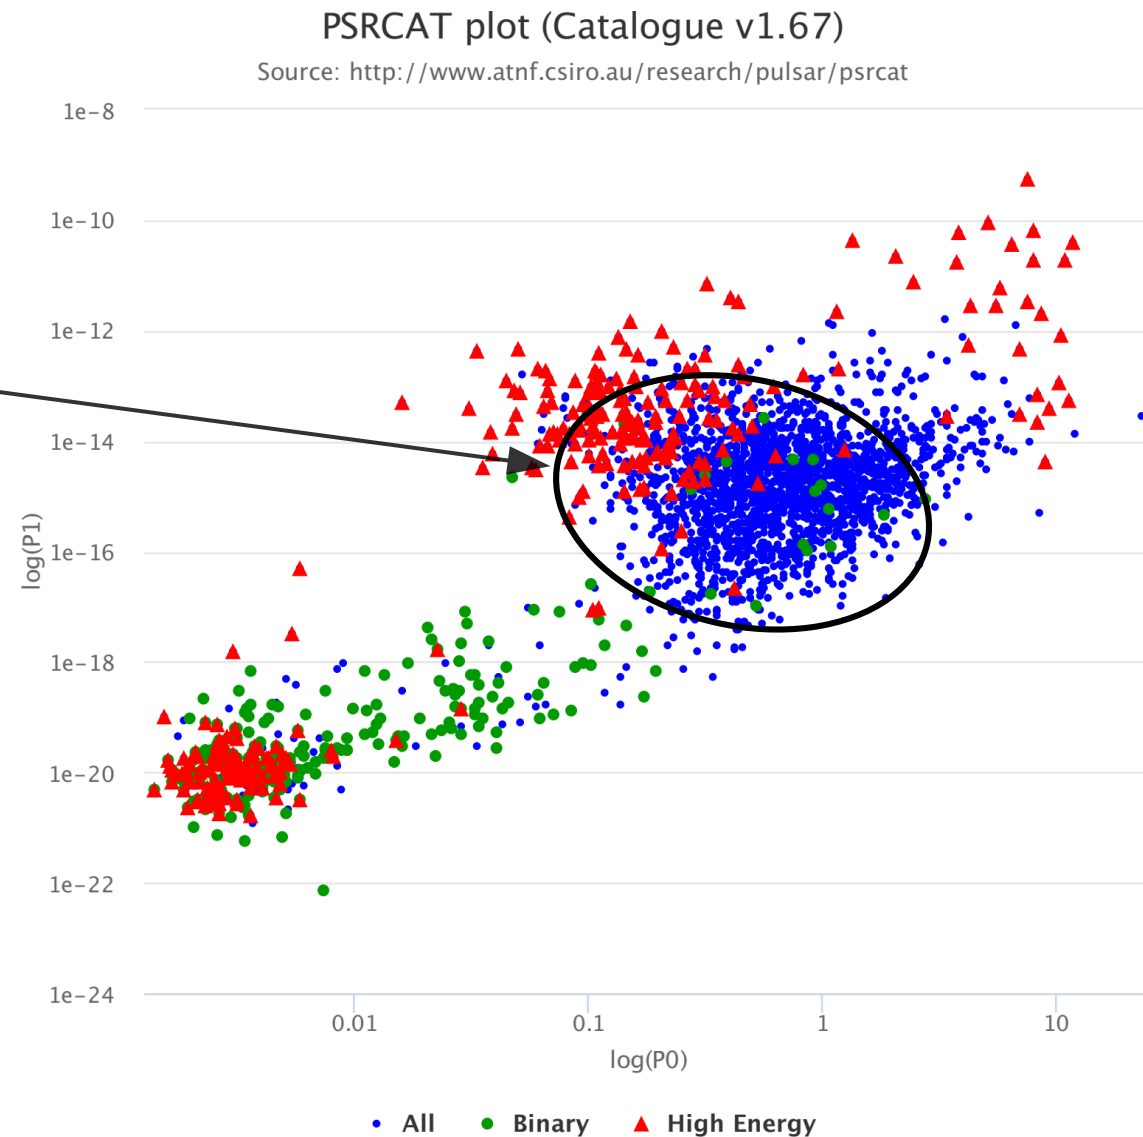

Observations

Canonical population:

- Non-binaries
- $P > 20$ ms
- No magnetars

$\log(\dot{E})$ (in W)	N_{tot}	N_{r}	N_{g}	N_{rg}
> 31	2	0	0	2
> 28	197	101	35	61
total	2665	2553	63	84

\dot{E} : spin-down luminosity

1 Galactic pulsar population

Pulsar population synthesis (PPS)

Goals:

- Inferring the underlying properties of pulsar population (P, \dot{P}, B, d)
- Predictions for future surveys (SKA)

2 approaches:

- Snapshot (Taylor & Manchester (1977), Lyne et al. (1985))
- Evolution (Faucher-Giguère & Kaspi (2006))

Model:

Magnetosphere

- Force-free magnetosphere + evolution of the inclination angle + magnetic field decay **applied to both radio and gamma-ray pulsars**

Emission:

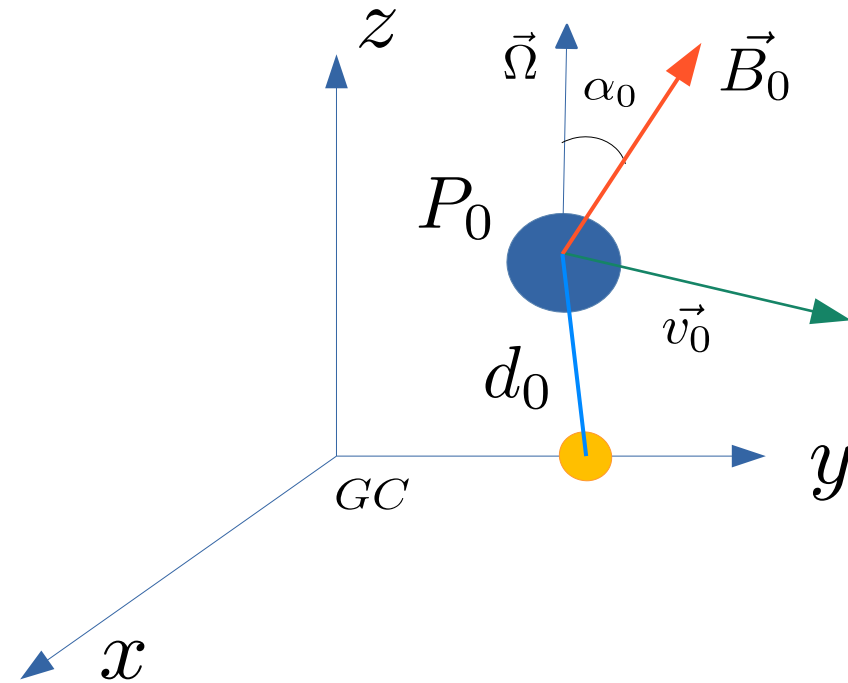

- Polar cap model for radio emission
- **Striped wind model for the pulsed gamma ray emission**

2 Model

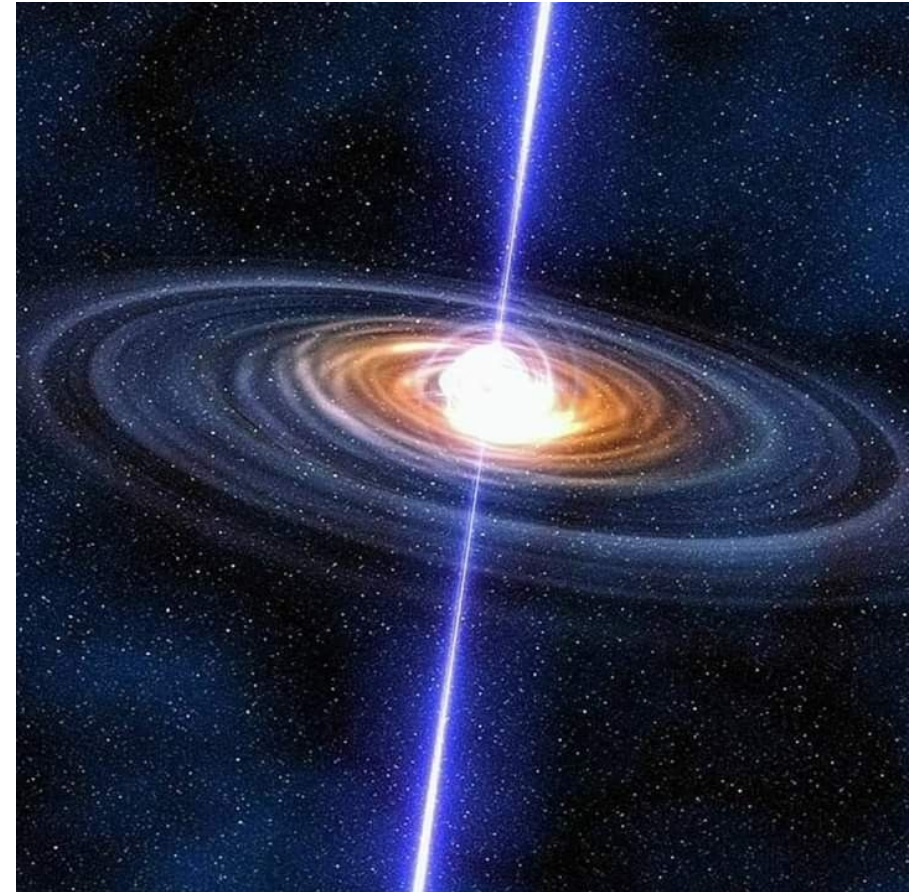

Generating a synthetic pulsar population

- 10^7 pulsars simulated with constant birth rate
- Initial intrinsic parameters:
 - B_0 : initial magnetic field (constant)
 - P_0 : initial period
 - α_0 : inclination angle at birth
 - \hat{n}_Ω : unit vector along the rotation axis
 - \vec{v}_0 : initial kick velocity
 - (x_0, y_0, z_0) : initial position

- Pulsars are evolved from their birth to the present $(P, \dot{P}, \alpha, B, d)$

- Luminosity of the pulsar
 - Radio (Johnston et al. (2020))
 - Gamma (Kalapotharakos et al.(2019))
- Sensitivity of the instruments:
 - Fermi/LAT (gamma)
 - Radio ~ 0.15 mJy (Parkes and Arecibo)
- Beaming fraction:
 - Emission beaming toward us in radio and/or gamma

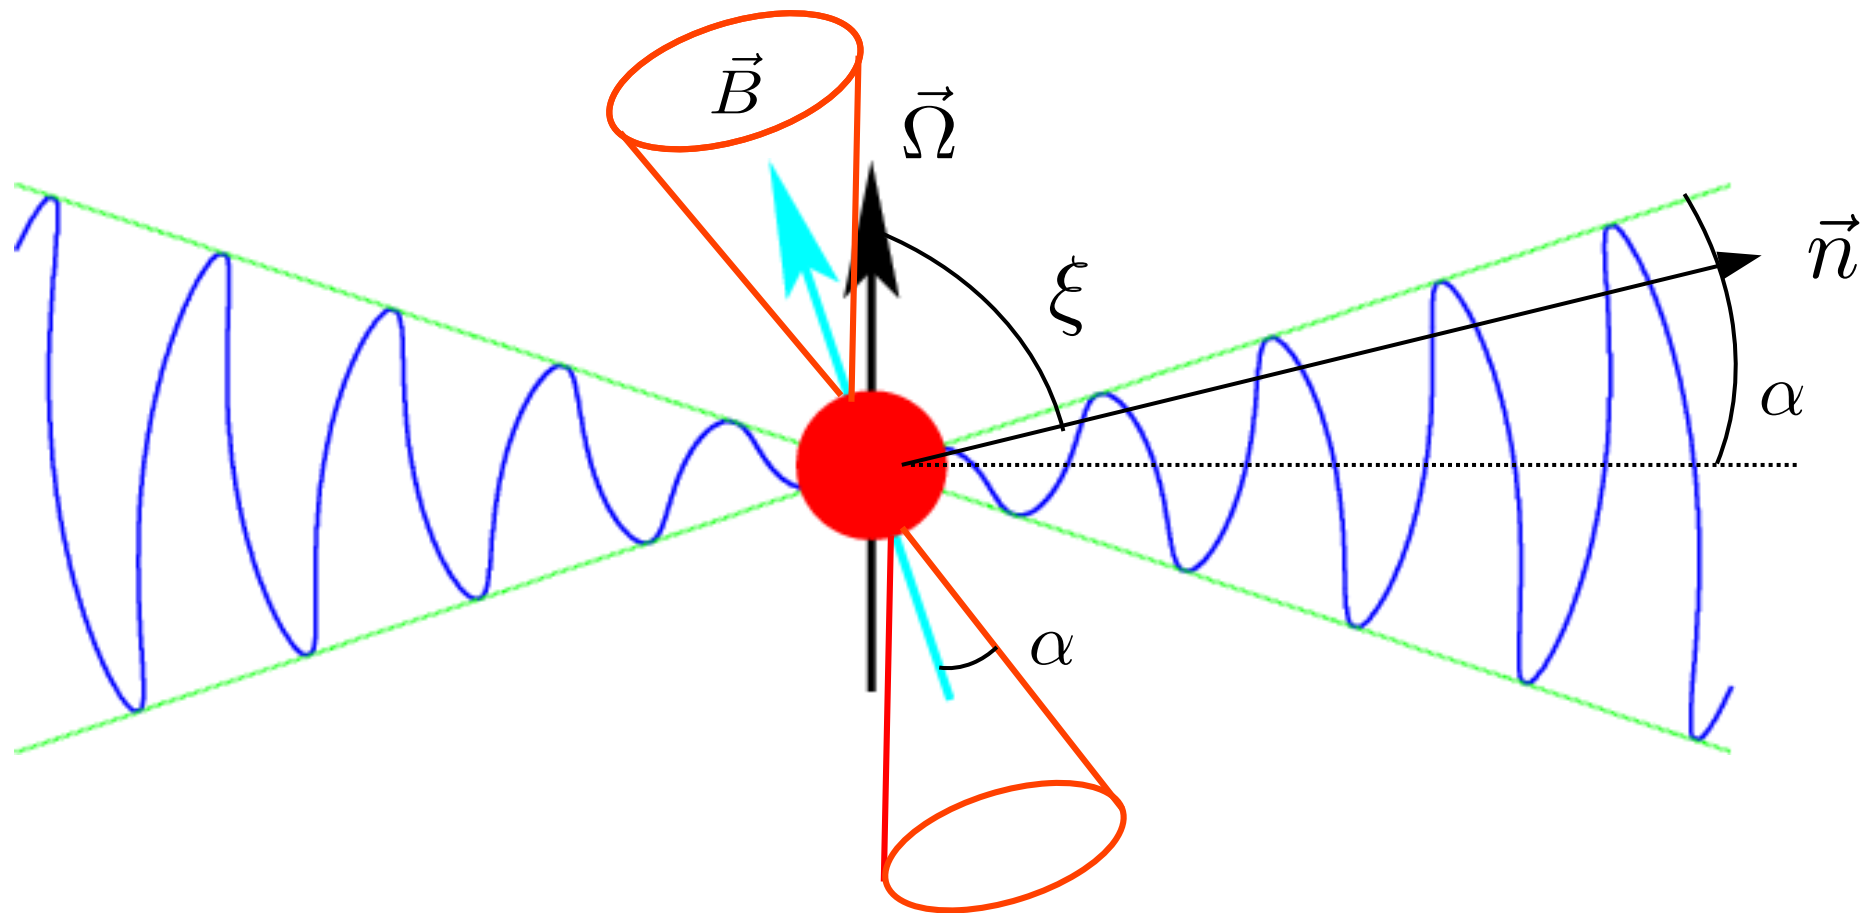

2

Model

Beaming fraction

Striped wind

Polar cap model

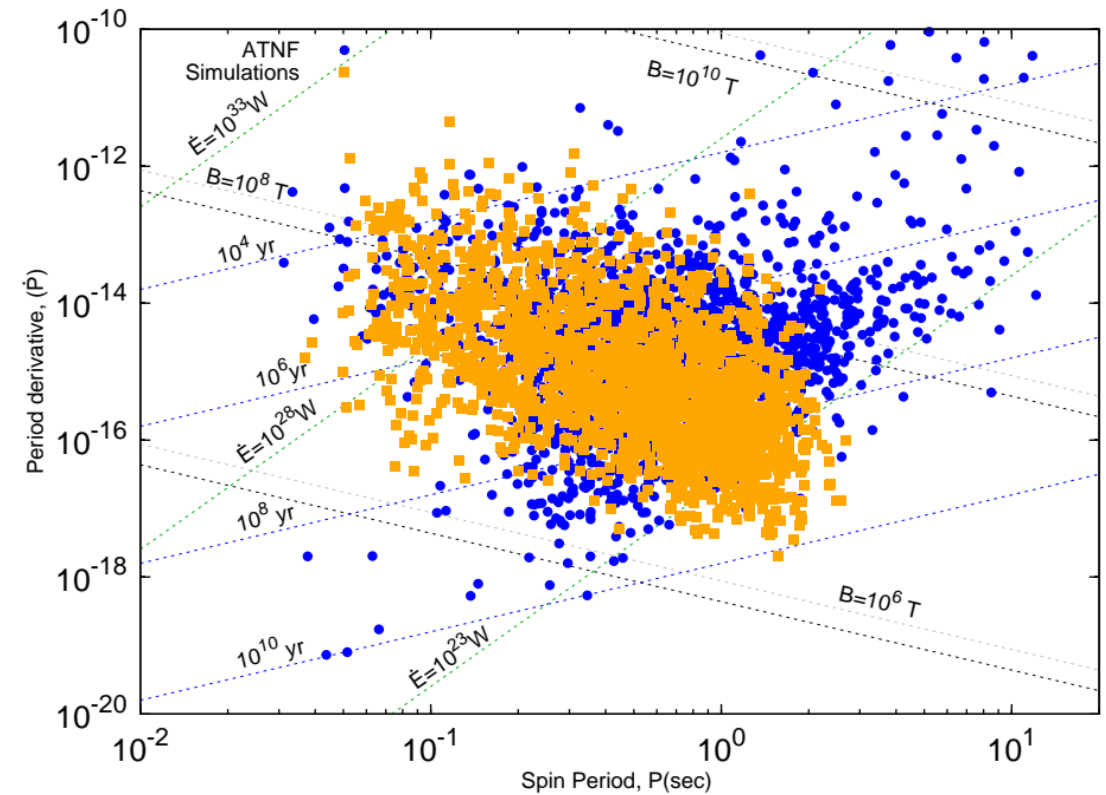

2 Model

P- \dot{P} diagram

τ_{birth} (1/yr)	P_{mean} (ms)	B_{mean} (T)	$\bar{\tau}_d$
70	60	2.5×10^8	4.6×10^5 yr

- More pulsars for lower \dot{P} .
- Long period pulsars slow down less rapidly.
- Sensitive to the initial distributions of P , \dot{P} and B . (Igoshev et al. 2022)
- Modelling the ISM

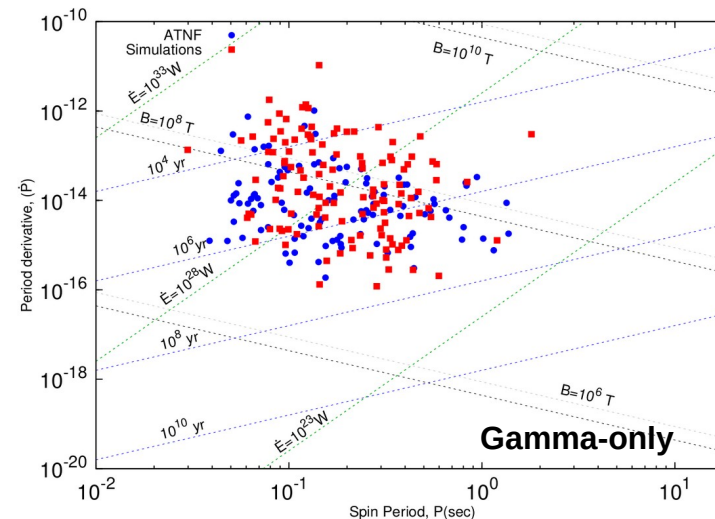

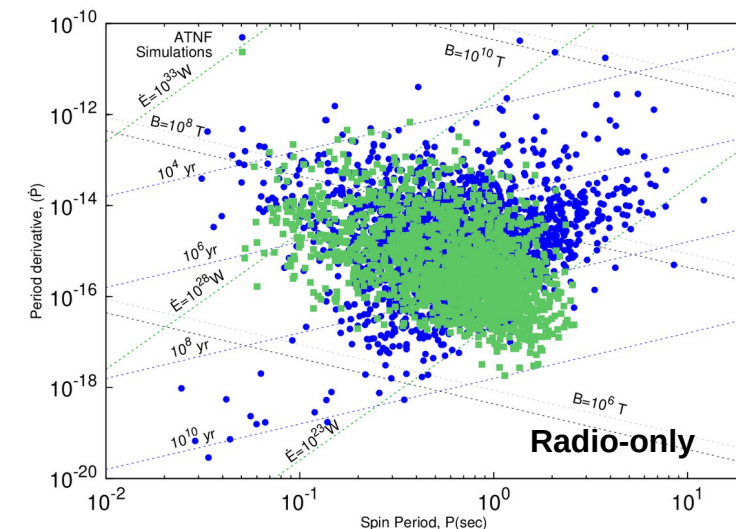

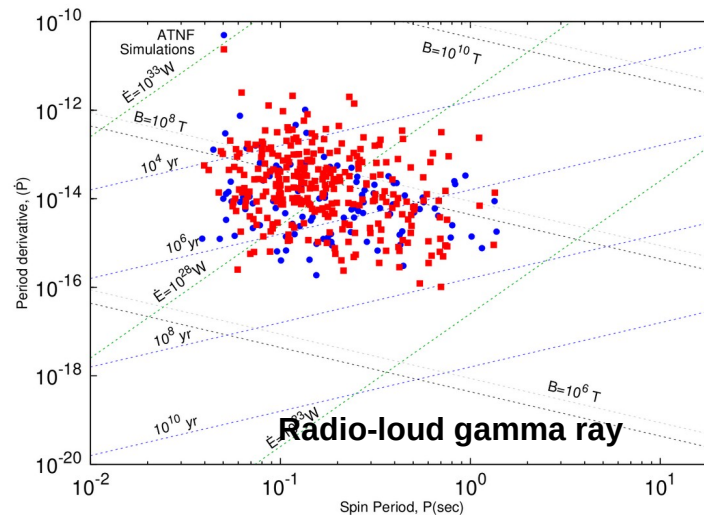

Simulations

$\log(\dot{E})$ (in W)	N_{tot}	N_{r}	N_{g}	N_{rg}
> 31	3	0	1	2
> 28	238	87	47	104
total	2155	1864	122	169

Observations

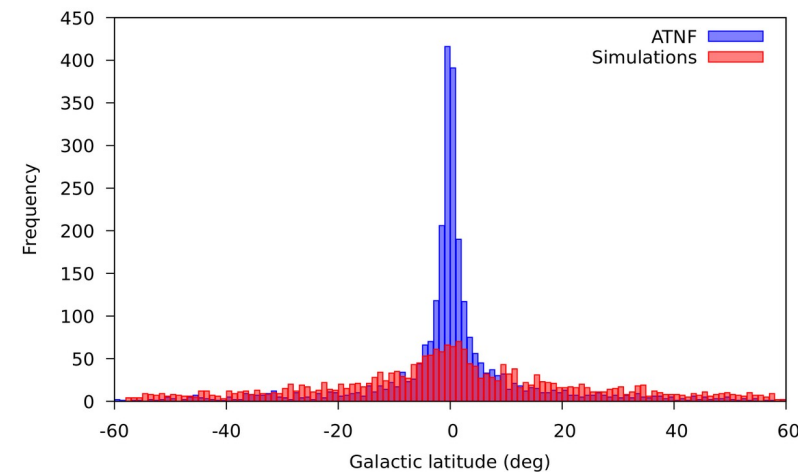

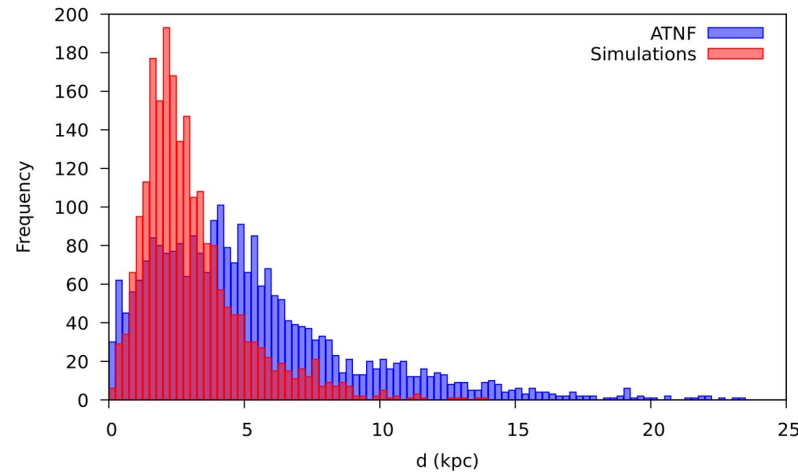

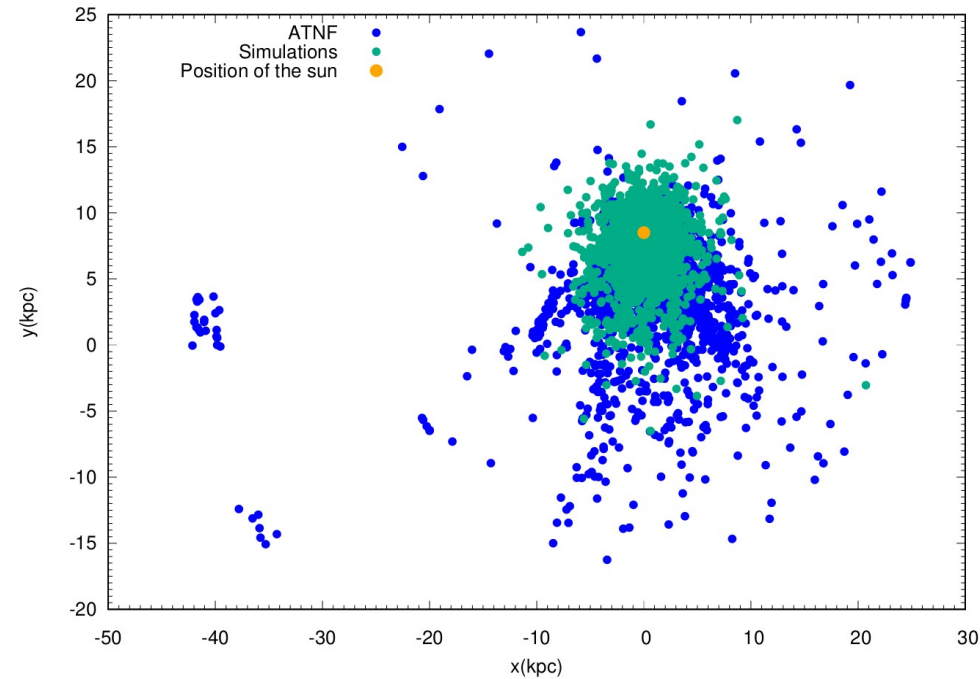

$\log(\dot{E})$ (in W)	N_{tot}	N_{r}	N_{g}	N_{rg}
> 31	2	0	0	2
> 28	197	101	35	61
total	2665	2553	63	84

3

Results

Spatial distribution

- Observed distance not accurately determined (model dependent).
- More refined treatment of the sensibility depending on the latitude
- Better description of the initial spatial distribution + birth kick velocity should be implemented.
- Take into account the galactic potential.

$$F_r \propto \left(\frac{1}{d}\right)^2 \left(\dot{E}\right)^{1/4}$$

3 Results

Effects of geometry and S_{min} on the detection of gamma pulsars

Pulsar type	Model	Geometry	Observations
N_r/N_{tot}	84%	6%	95%
N_g/N_{tot}	7%	84%	2%
N_r/N_{tot}	9%	9%	3%

Still a lot of gamma-ray pulsars to be detected!!

Pulsar type	S_{min}	$S_{min}/2$	$S_{min}/5$
N_r/N_{tot}	84%	76%	57%
N_g/N_{tot}	7%	12%	26%
N_r/N_{tot}	9%	12%	17%

Deep follow-up surveys at 1.4 GHz of gamma-ray sources:

if $\text{glat} < 2^\circ$, $S_{min} = 4 \times 10^{-15} \text{ Wm}^{-2}$

Blind survey

$S_{min} = 16 \times 10^{-15} \text{ Wm}^{-2}$

Summary

1 2 3 4

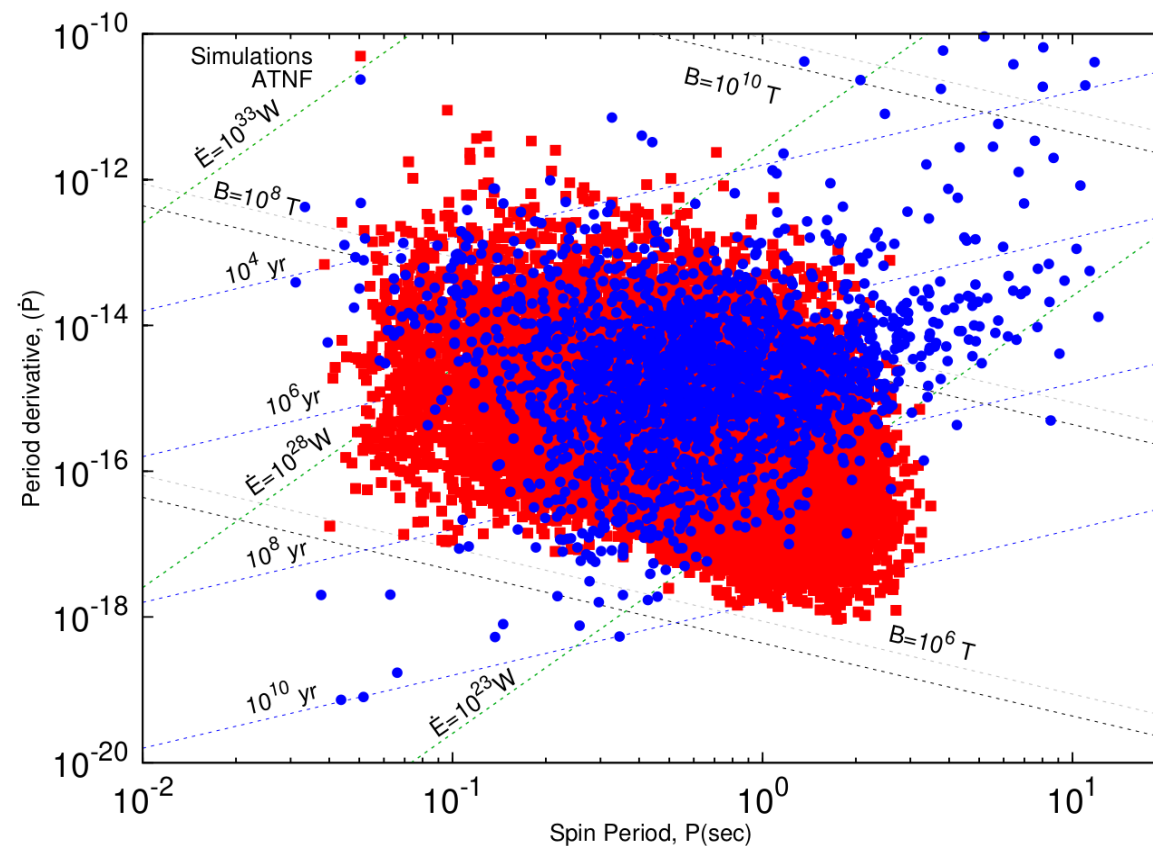

- Force-free evolution scenario + magnetic field decay + striped wind emission model for gamma-rays.

→ reproduce satisfactorily P- \dot{P} diagram and the number of detected pulsars.

- PPS are valuable and reliable tool to constrain the basic physics of neutron star electrodynamics and for **predictions**.

- Future prospects:
 - Galactic potential
 - Effect of the ISM
 - Radio emission death line

Prediction for SKA (50 times more sensitive): ~ 27000 detected pulsars

Tenth International Fermi Symposium

9th-15th October 2022

Model

Generating a synthetic pulsar population

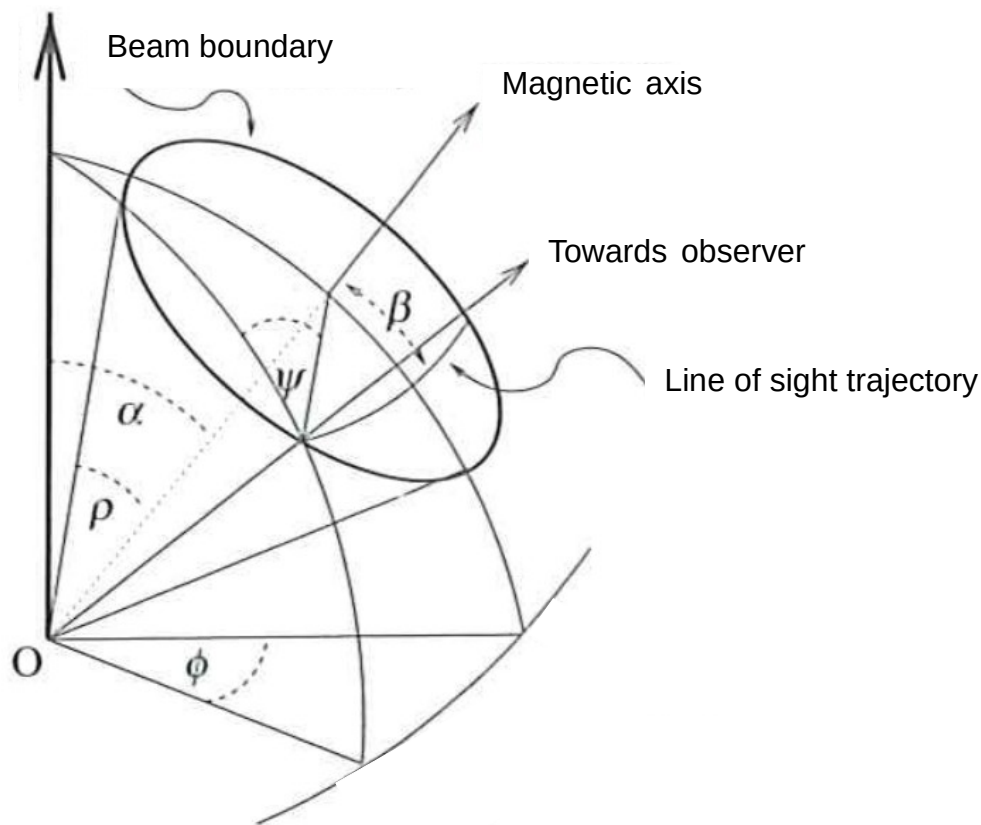

Pulsar's intrinsic parameters:

- B_0 : initial magnetic field (constant) **(Gaussian in log space)**
- P_0 : initial period **(Gaussian)**
- α_0 : inclination angle at birth **(Isotropic)**
- \mathbf{n}_Ω : unit vector along the rotation axis **(Isotropic)**
- \mathbf{v}_0 : initial kick velocity **(Maxwellian)**
- (x_0, y_0, z_0) : initial position
- d : distance to Earth
- P and \dot{P} : current period and its time derivative
- α , current inclination angle

Model

Beaming fraction: radio

Rotation axis

$$\rho \propto \frac{1}{\sqrt{P}}$$

- Pulsar *can* be detected if

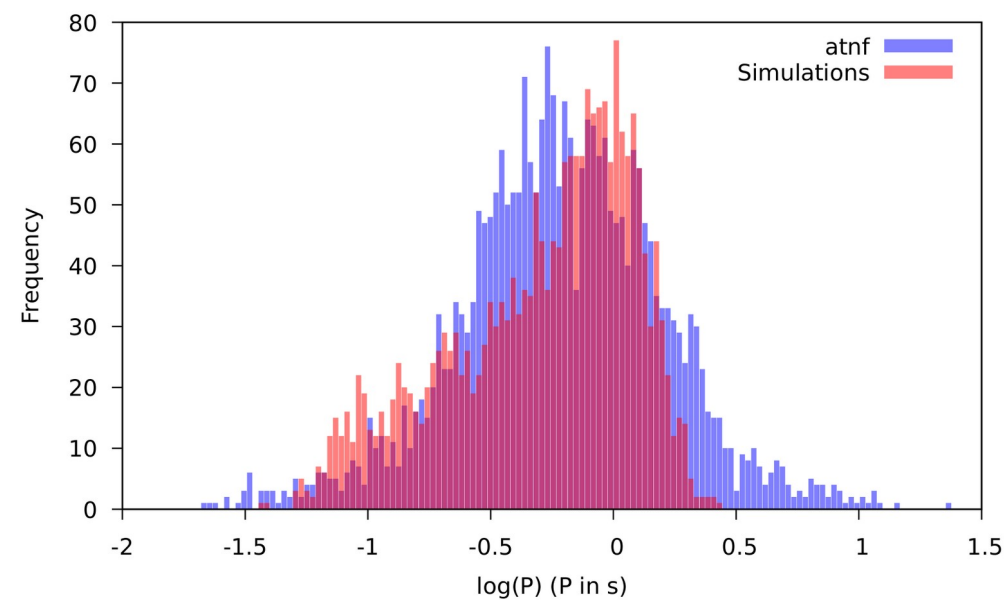

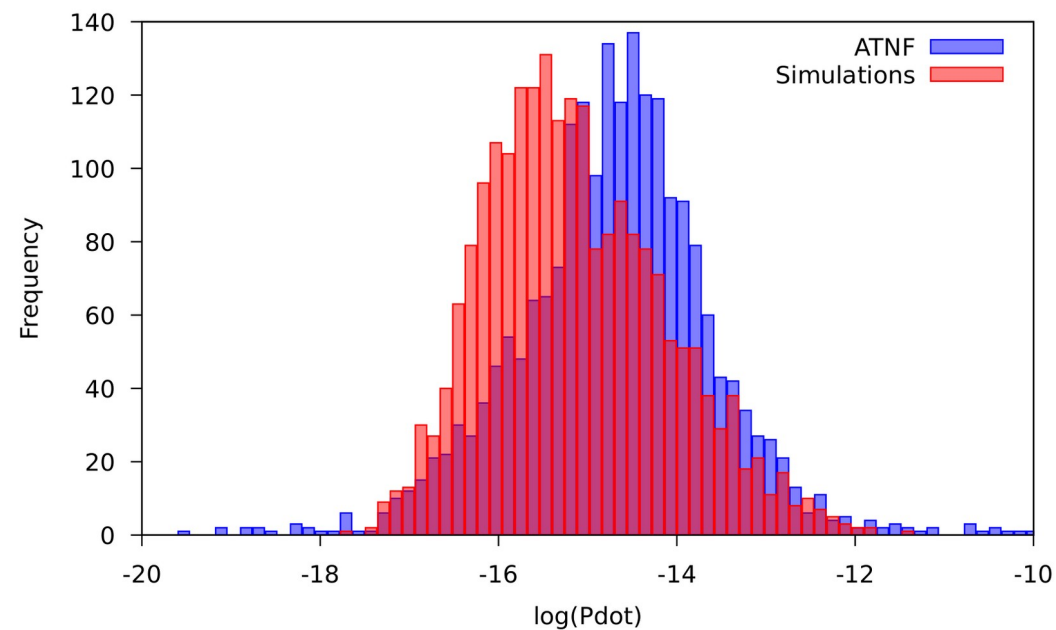

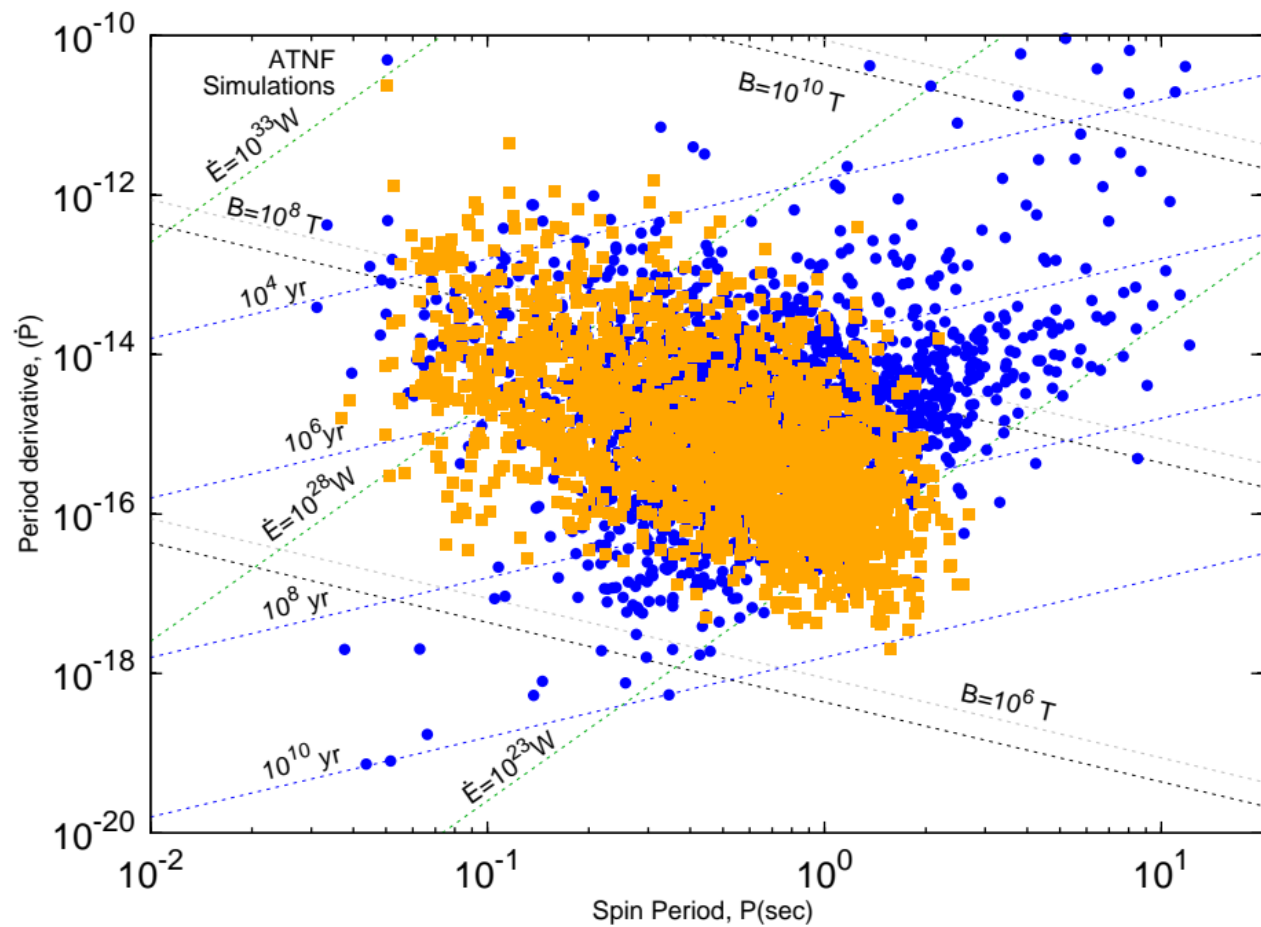

$$\beta = |\xi - \alpha| \leq \rho$$

or

$$|\xi - (\pi - \alpha)| \leq \rho$$

P- \dot{P} diagram

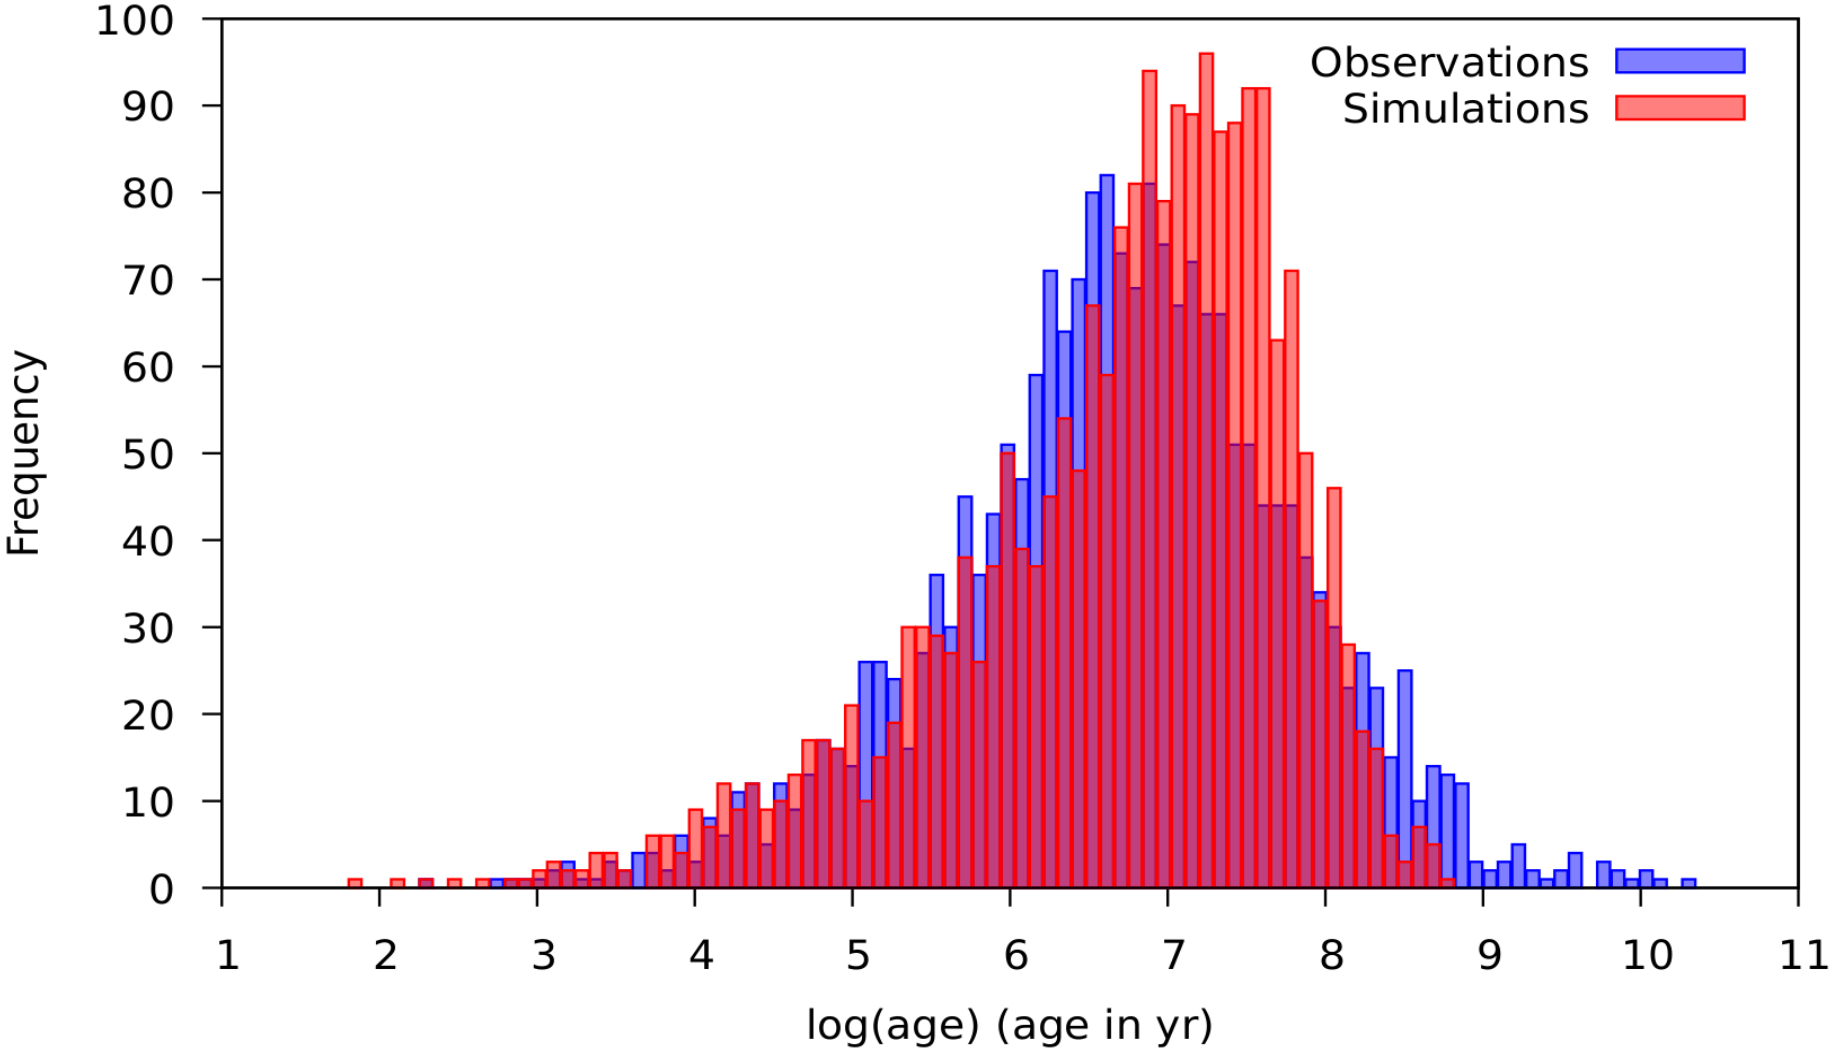

Results

P- \dot{P} diagram

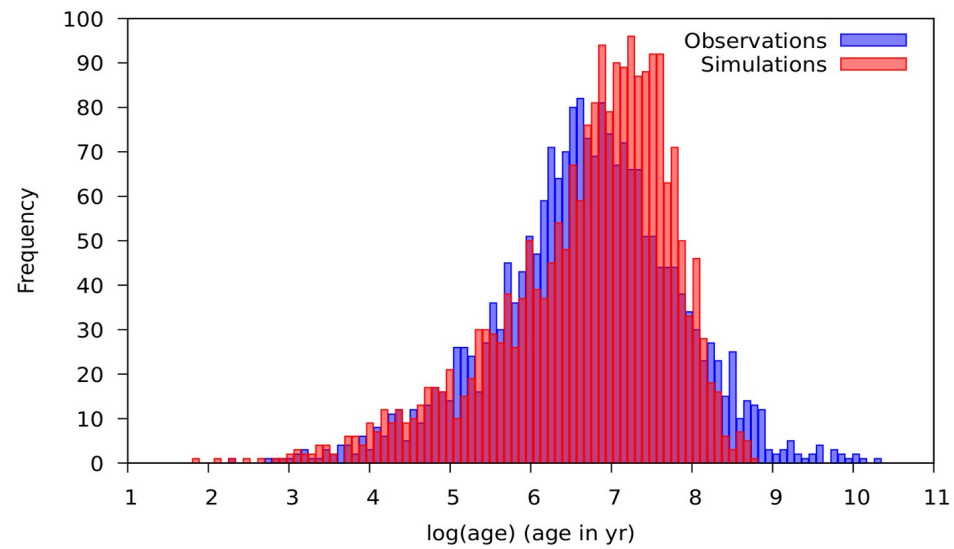

Results

Age of detected pulsars

Results

Age of detected pulsars

Model

Radio luminosity and sensitivity

- Radio flux density at 1.4 GHz:

$$F_r = 9 \text{ mJy} \left(\frac{d}{1 \text{ kpc}} \right)^{-2} \left(\frac{\dot{E}}{10^{29} \text{ W}} \right)^{1/4} 10^{F_j}$$

- Signal-to-noise ratio:

$$S/N = \frac{F_r}{S_{\text{survey}}^{\text{min}}}$$

- Minimum detectable flux of a pulsar survey:

$$S_{\text{survey}}^{\text{min}} = S_0 \sqrt{\frac{\tilde{w}_r}{P - \tilde{w}_r}}$$

Parkes multibeam survey and Arecibo surveys have a sensitivity of $\sim 0.15 \text{ mJy}$

Model

Gamma luminosity and sensitivity

$$L_{\gamma(2D)} = 10^{26.15 \pm 2.6} \text{ W} \left(\frac{B}{10^8 \text{ T}} \right)^{0.11 \pm 0.05} \left(\frac{\dot{E}}{10^{26} \text{ W}} \right)^{0.51 \pm 0.09}$$

Kalapotharakos et al. (2019)

Fermi/LAT sensitivity to pulsars:

- at galactic latitude $< 2^\circ$ is $F_{\min} = 4.10^{-15} \text{ W.m}^{-2}$
- For blind searches: $F_{\min} = 16.10^{-15} \text{ W.m}^{-2}$

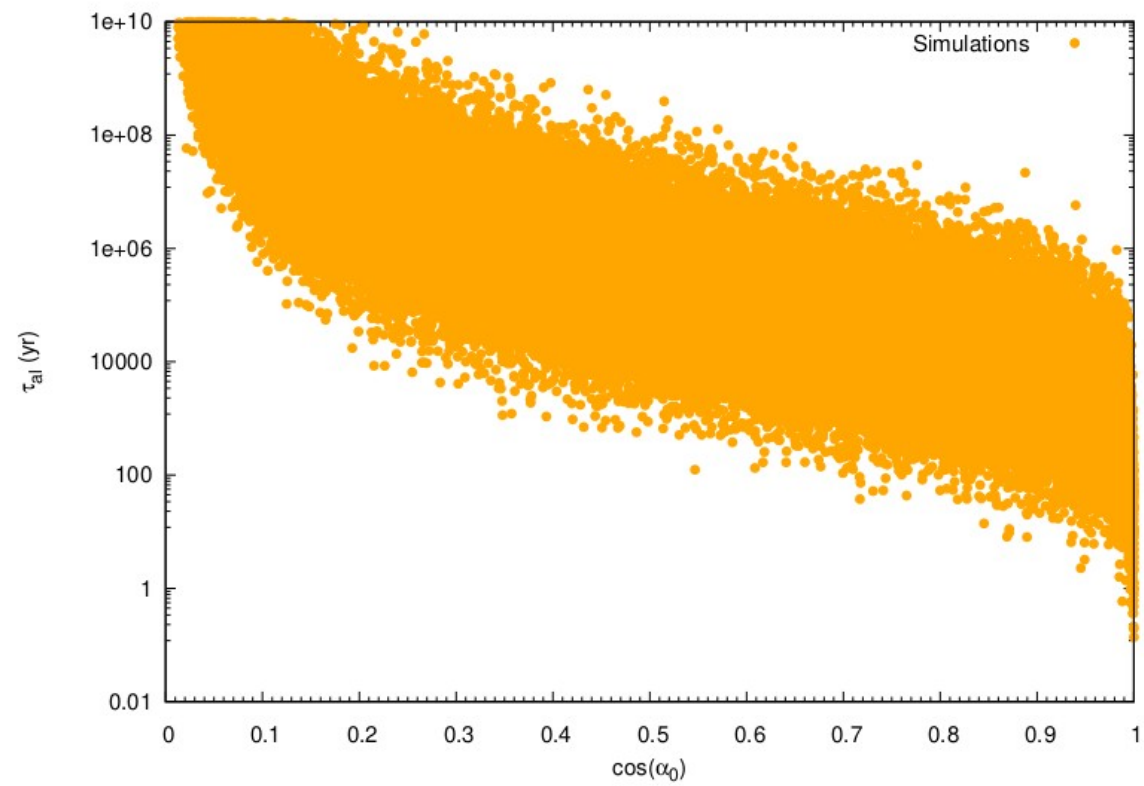

- Vacuum rotator: $\sin \alpha(t) = \sin \alpha_0 \exp \left(-t / \tau_{align}^{vac} \right)$
- In the MHD case, $\alpha \propto t^{-1/2}$
- For a force-free magnetosphere, integral of motion is:

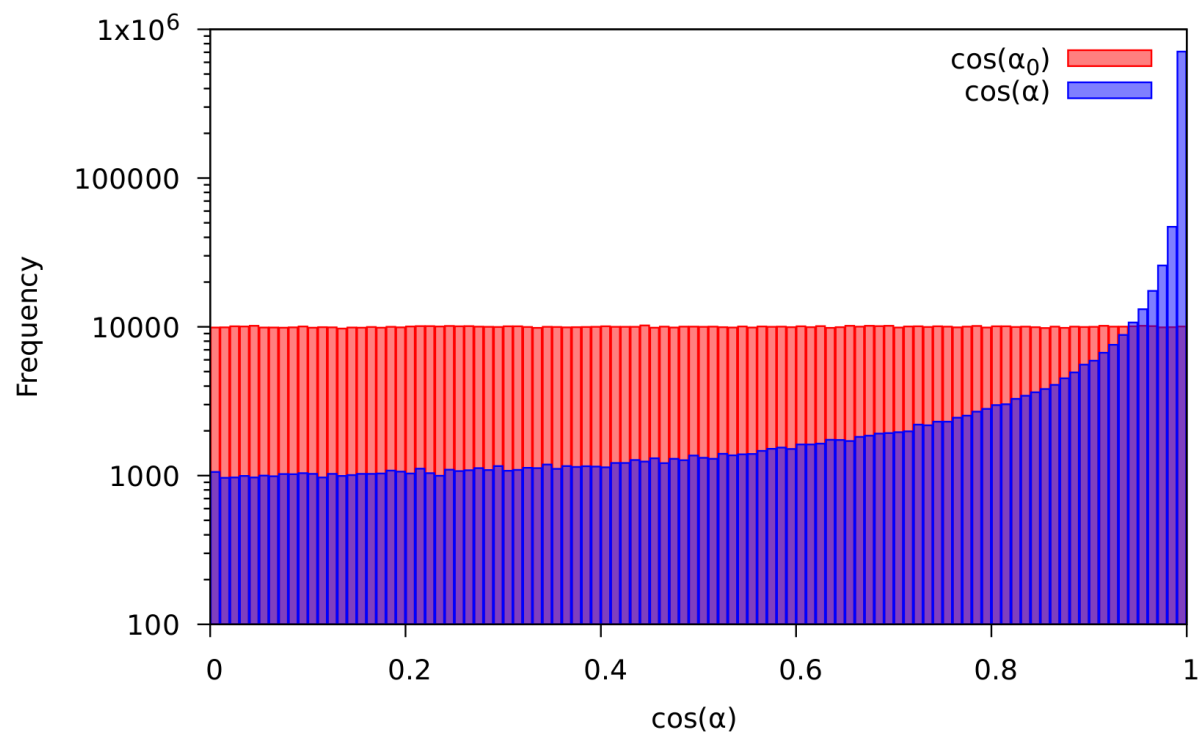

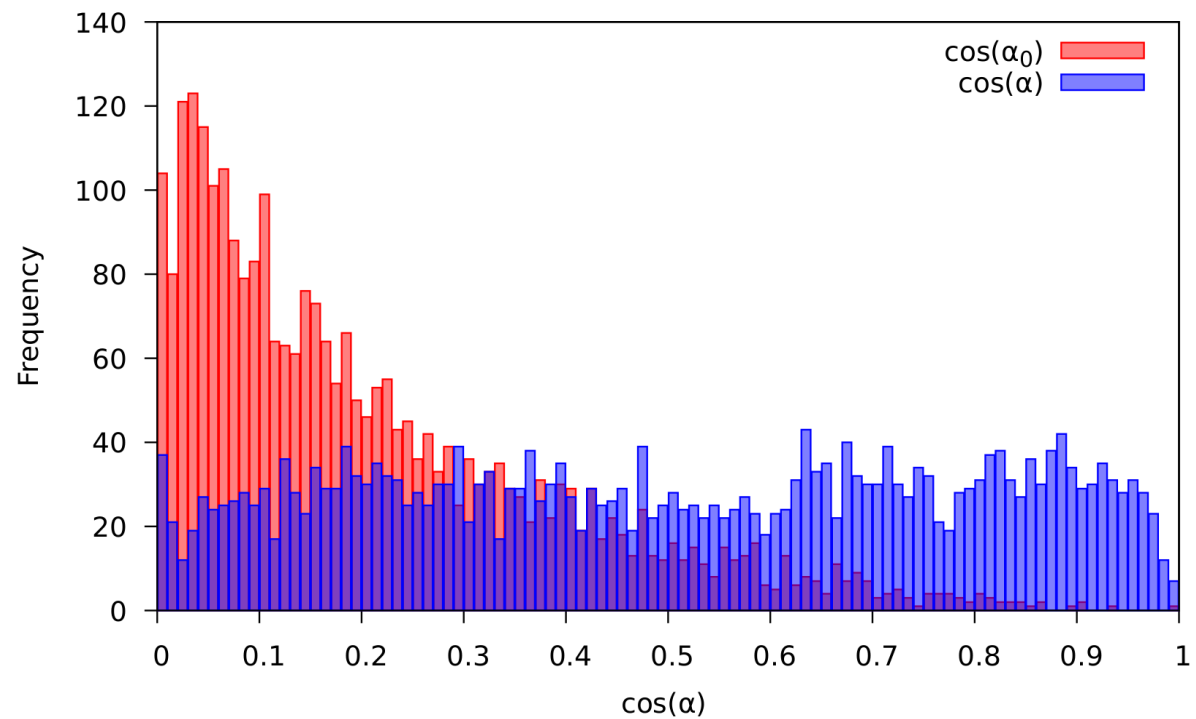

Philippov et al. 2014

$$\Omega \frac{\cos^2 \alpha}{\sin \alpha} = \Omega_0 \frac{\cos^2 \alpha_0}{\sin \alpha_0}$$

$$I \dot{\Omega} = -\frac{3}{2} \frac{L_{\perp}}{\Omega} (1 + \sin^2 \chi)$$

$$I \Omega \dot{\chi} = -\frac{3}{2} \frac{L_{\perp}}{\Omega} \cos \chi \sin \chi.$$
