MAPP LHCC REFEREE QUESTIONS

FEATURES

- High gain 1.0×10^7
- $\phi 80$ mm Hemisphere...R14374
- $\phi 90$ mm Hemisphere...R14689

APPLICATIONS

- High energy physics

SPECIFICATIONS

GENERAL

Parameter	R14374	R14689	Unit
Spectral response	300 to 650		nm
Wavelength of maximum response	420		nm
Window material	Borosilicate glass		—
Photocathode	Material	Bialkali	—
	Minimum effective area	71	cm ²
Dynode	Structure	10	—
	Number of stages	10	—
Base	EC No. 5-58		—
Operating ambient temperature	-30 to +50		°C
Storage temperature	-30 to +50		°C
Suitable socket	9299-140 (Socket 9-pin)		—

MAXIMUM RATINGS (Absolute maximum values)

Parameter	R14374	R14689	Unit
Supply voltage	300		V
Average anode current	0.1		mA

CHARACTERISTICS (Typ. @ 20°C)

Parameter	R14374	R14689	Unit
Cathode sensitivity	Luminous (2856 K)	90	μA/lm
	Radiant at 420 nm	90	mA/W
	Blue sensitivity index (CS 5-58)	11.0	—
	Quantum efficiency at 380 nm	27.5	%
Anode sensitivity	Luminous (2856 K)	900	A/lm
	Radiant at 420 nm	9.0×10^5	A/W
Gain	1.0×10^7		—
Anode dark current (After 30 minute storage in darkness)	50		nA
Time response	Anode pulse rise time	2.9	ns
	Electron transit time	35	ns
	Transit time spread (FWHM)	1.3	ns

NOTE: Anode characteristics are measured with a voltage distribution ratio and supply voltage shown below.

Photomultiplier Tube

10-stage
80mm (3.1"), Round tube

Application

High energy physics, Low profile

Description	Features
Window material	Borosilicate low K
Photocathode	10A1
R.C. Index at 420nm	1.54
Multiplier structure	Box and Linear focused

Photocathode characteristics	Min.	Typ.	Max.	Unit
Spectral range	300-650			nm
Maximum sensitivity at	404			nm
Sensitivity	Luminous	110	2.5	A/lm
	Quantum efficiency at 404 nm	25	—	%
Quantum efficiency at 470 nm*	18	—	—	%
Gain (vs supp. Volt. log/log)	8.3	—	—	—
For an anode blue sensitivity of 1000000	50	—	—	MinF
Gain	3×10^5	—	—	—
Anode dark current	10	30	—	nA
Dark count*	600	2000	—	cps
Mean anode sensitivity deviation:	—			—
Low	—	—	—	—
High	—	—	—	—
vs temperature between 0 and +40°C at 400 nm	-0.3	—	—	%/K
vs temperature between 0 and +40°C at 400 nm	—	—	—	—
Anode pulse:	—			—
Transit time	49	—	—	ns

Recommended Voltage Divider

Type A for maximum gain

K	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	A
3	2	1	1	1	1	1	1	1	1	1	1

(Total: 14)

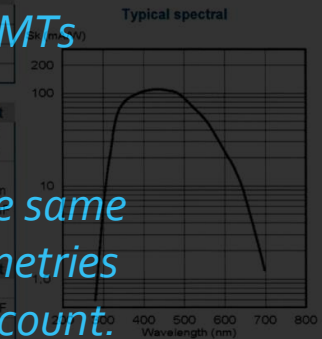

* characteristic measured and mentioned on the test ticket of each tube

It's mentioned that the HZC PMTs will be partially replaced by Hamamatsu PMTs (100). Would you be able to clarify more how this is implemented and the possible differences, as the two types of PMTs presumably have a different performance?

Also, are the 100 PMTs from Hamamatsu just put together in the same section? What I am wondering is possible differences and asymmetries between the different PMTs that would need to be taken into account.

The first two MAPP frames will already be installed so the 100 Hamamatsu PMTs will be distributed in the 3rd and 4th frame. Intermixing detectors with HZC and Hamamatsu PMTs will allow one to do comparisons between the two using both cosmic ray and LHC muons

PMT Characteristics

- The HZC and Hamamatsu PMTs have very similar characteristics
- The HZC tube has a lower dark current but also a lower gain
- The photocathodes have slightly different responses
- Difference between PMTs not expected to be observable

	HZC Photonics XP72B22	Hamamatsu R14374
Tube Size	3-inch	3-inch
Tube shape	Circular	Circular
Window material	Borosilicate glass	Borosilicate glass
Photocathode	Bialkali	Bialkali
Spectral response	300 -650nm	300-650nm
Quantum efficiency	25% at 404 nm	27% at 380nm
Gain	3×10^6	10^7
Rise time	3.5 ns	2.9 ns
Anode dark current	10 nA	50 nA
Maximum operating voltage	1300 V	1500 V

Detector Calibration

- *Could you clarify the calibration or pre-calibration performed before the scintillators and PMTs are installed. You mention that in section 2.1.2, but it would be good to highlight what “pre-calibration” is done in the lab and whether it appears in the resource-loaded spreadsheet.*
- A pre-calibration will be carried out on 25% of the bars using cosmic rays in a system that allows us to test 4 bars at a time. Test will be performed with the bars placed both vertically and horizontally.
- These bars will be placed on the top layer of each section. During the run, vertical cosmic rays that traverse all layers of scintillator will be recorded allowing a cross-calibration of all bars against these pre-calibrated ones.

Muon Trigger

- *What is the efficiency of the muon trigger described on page 11?*
- Trigger = Hits in 4 bars and 3 photon tagging with no veto
- The muon signal in the main bars is too large to be missed unless it falls into the detector deadtime between events
- Pb-scintillator photon tagging detector efficiency for MIPS will be high but must be directly measured with final detector
- Effect of VETO panels on muon trigger efficiency depends on rate, must be measured in situ. However, we use software not hardware triggers so these events are not automatically rejected

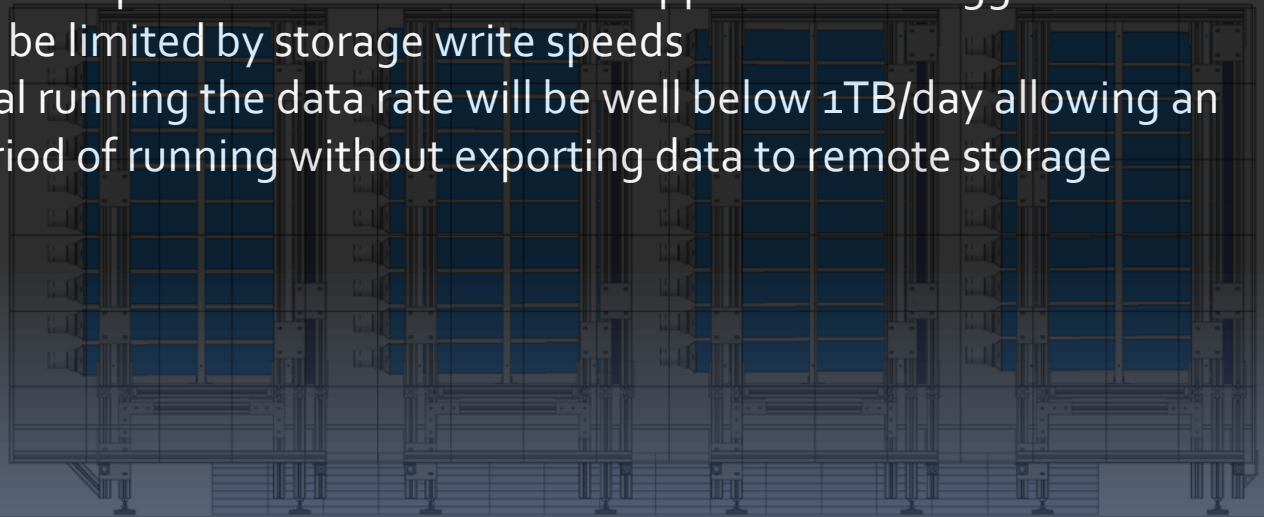

Data Storage

- *Could you clarify what the storage is with the onsite computer in case the 1 Gbit/s ethernet link to an external computer doesn't work? Would you lose any data in case of a failure or inability to send the data outside?*

- The DAQ server will have local disk storage of 40TB
- Initially the fewest possible restriction will be applied to the trigger and the data rate will be limited by storage write speeds
- During normal running the data rate will be well below 1TB/day allowing an extended period of running without exporting data to remote storage

Signal Yield

- *What is the signal yield you expect out of a bar for a muon that travels the whole length? In the calibration section (2.1.2), it is said that a MIP will produce 3×10^6 photons in 4 bars. What is much more relevant to judge the possible limits on fractional charges is however how many of those photons will be detected by their system. We don't think this is mentioned.*
- Nominal output from the scintillator is 9.7k photons/MeV
- A MIP traversing a bar should produce roughly 1.5M photons
- Realistic light collection efficiency about 5%
- If light production goes as Q^2 then a charge of 0.004 should produce approximately 1PE per bar
