Content

- A critical review of 3 recently published Odderon papers and methods:
 - 1) **Model independent:** $H(x)$ scaling
(Csörgő, Novák, Pasechnik, Ster, Szanyi, *EPJC* (2021) 81:180)
 - 2) **Model dependent:** Bialas-Bzdak model
(Csörgő, Szanyi, *EPJC* (2021) 81:611)
 - 3) **Semi model independent:** TOTEM-D0 extrapolation
(TOTEM-D0 Coll., *PRL* (2021) 127, 062003)
- $H(x)$ scaling of recently released 8 TeV elastic pp data
- New Levy description of elastic pp data (preliminary)
- Conclusion_{pp}

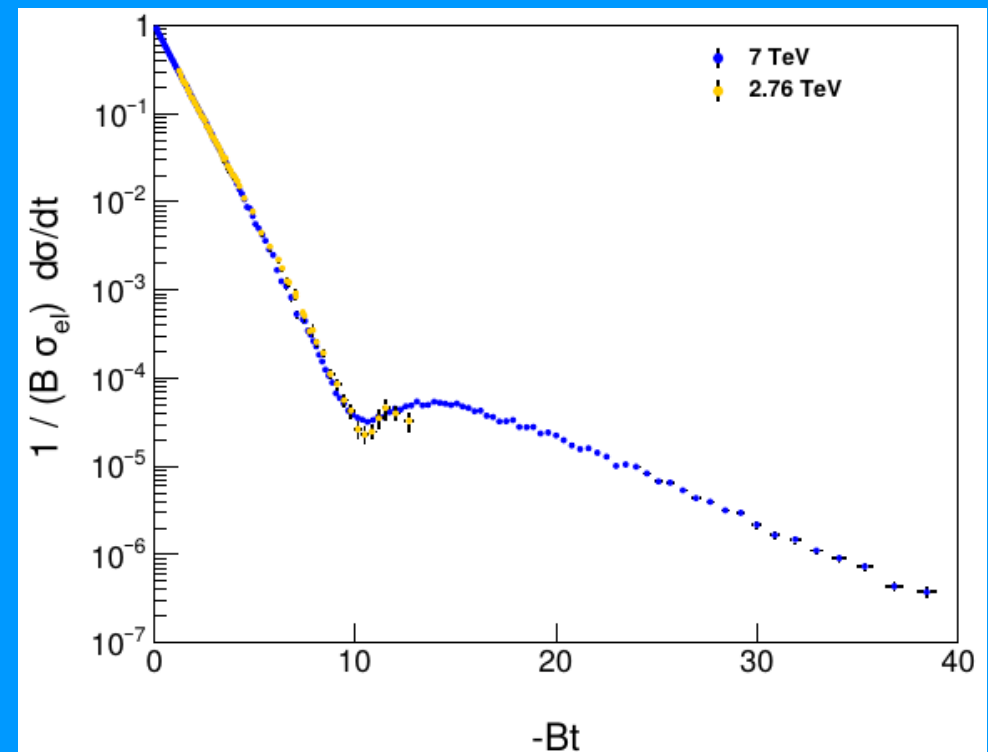

H(x) scaling

The scaling eliminates collision energy (s) dependencies and overall normalization problems (see example plots)

$$x = -tB$$

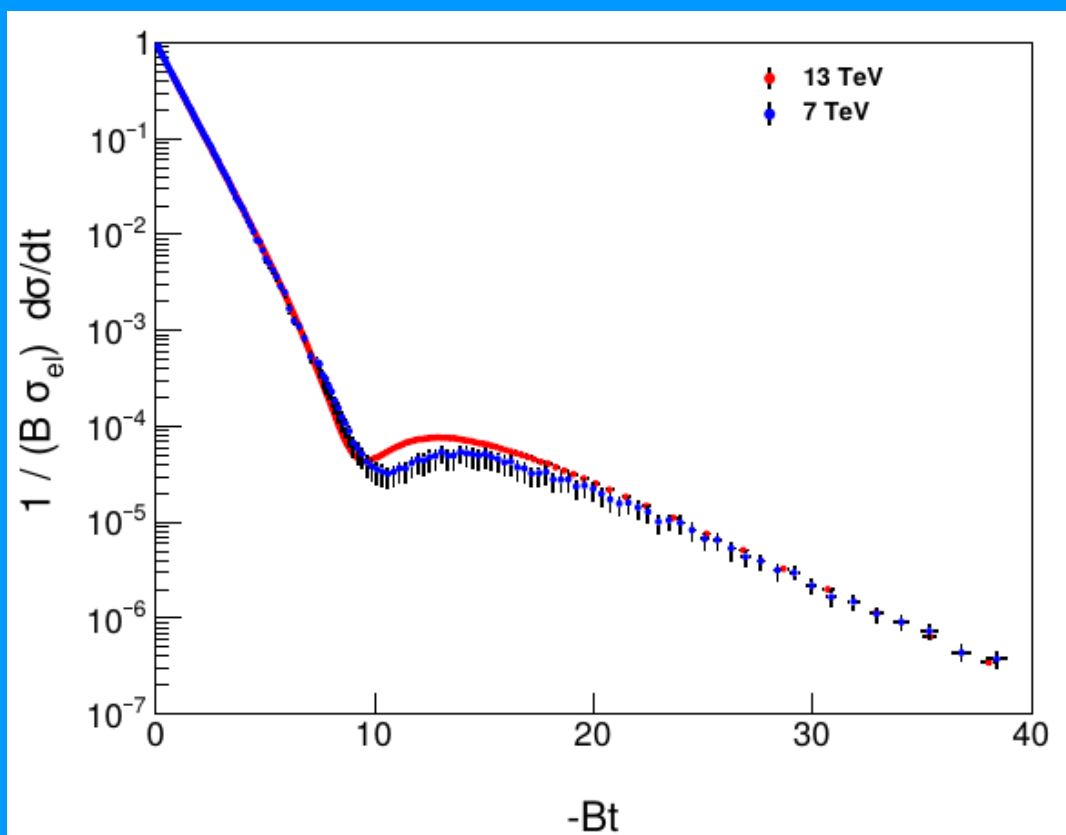

$$H(x, s) = (1 / B \sigma_{el}) d\sigma / dt$$

H(x) scaling

Scaling is approximate and fails above 3-4 factors in energy

Argument 1:

Studies like Odderon ones can be limited within a few TeV region from 1.96 to 8 TeV

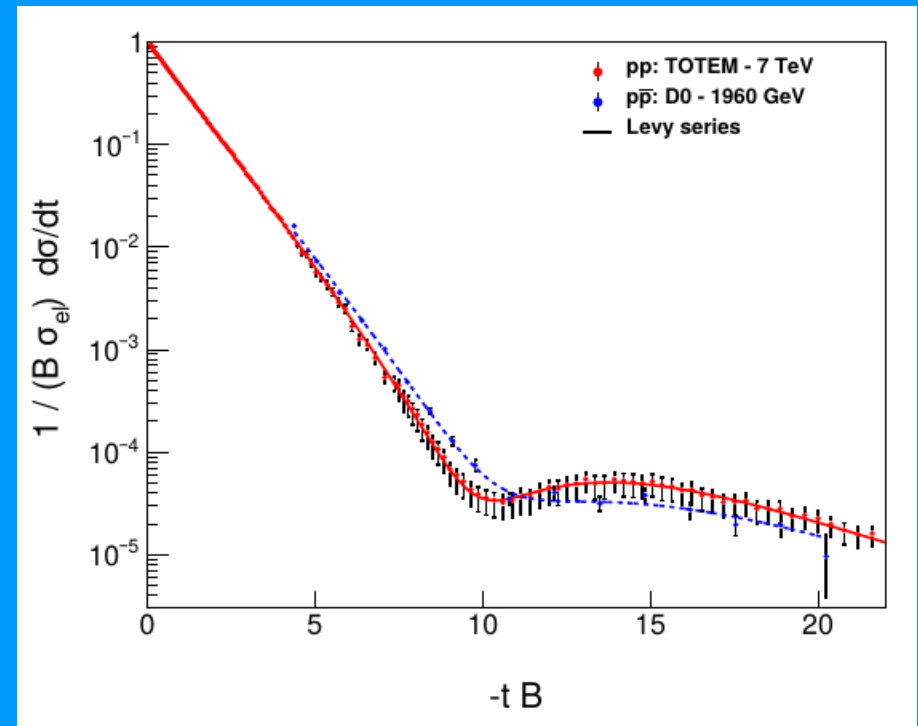

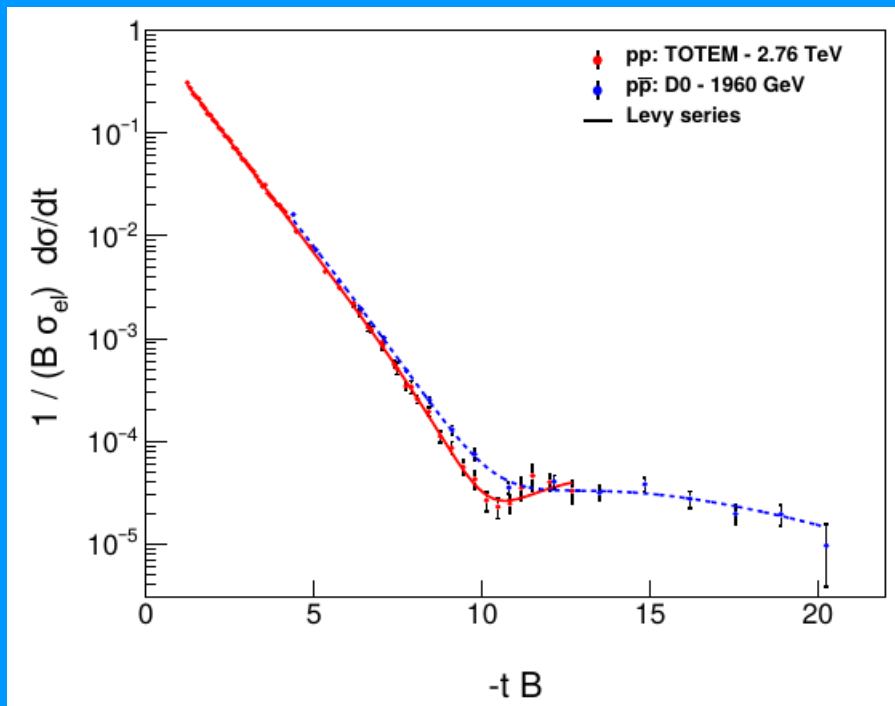

Argument 2:

At 13 TeV other effects, like hollowness have influence, too

H(x) scaling

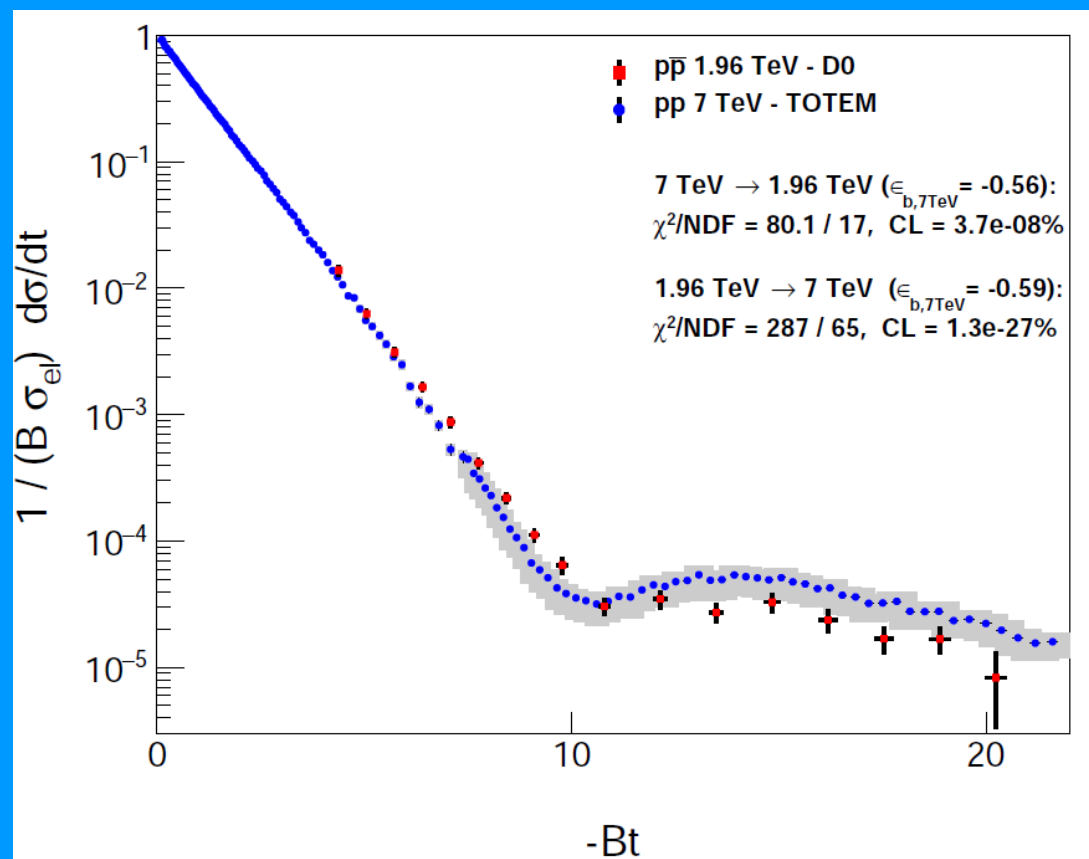

Scaling is not justified well enough beyond the dip and bump region

Arguments: 1) we give detailed study about its validity in the paper. 2) In case of 1.96 and 7 TeV H(x) their data are within systematic errors. 3) In addition, the Odderon signal mainly comes from before the dip

H(x) scaling

The significance of Odderon (6.26σ) is influenced by a not exact scaling

Argument 1:

It was shown, within a few factors in energy $H(x)$ distributions are within 1σ

Argument 2:

The final significance is the least value within the systematic errors of the $H(x)$'s. (Worst case scenario)

Bialas-Bzdak model

The model extrapolates pp and ppbar elastic scattering cross sections in a few TeV energy domain via the extrapolations of its model parameters extracted from fits to existing data sets

Corresponding fits, results and their plots can be seen in I. Szanyi's talk

The model does not work at very low- t region of elastic scattering
Argument: *relevant 1.96 TeV ppbar data are above this small $-t$ region*

It can not extrapolate to ISR energies and to 13 TeV
Argument: *Odderon search is concentrated in a few TeV region*

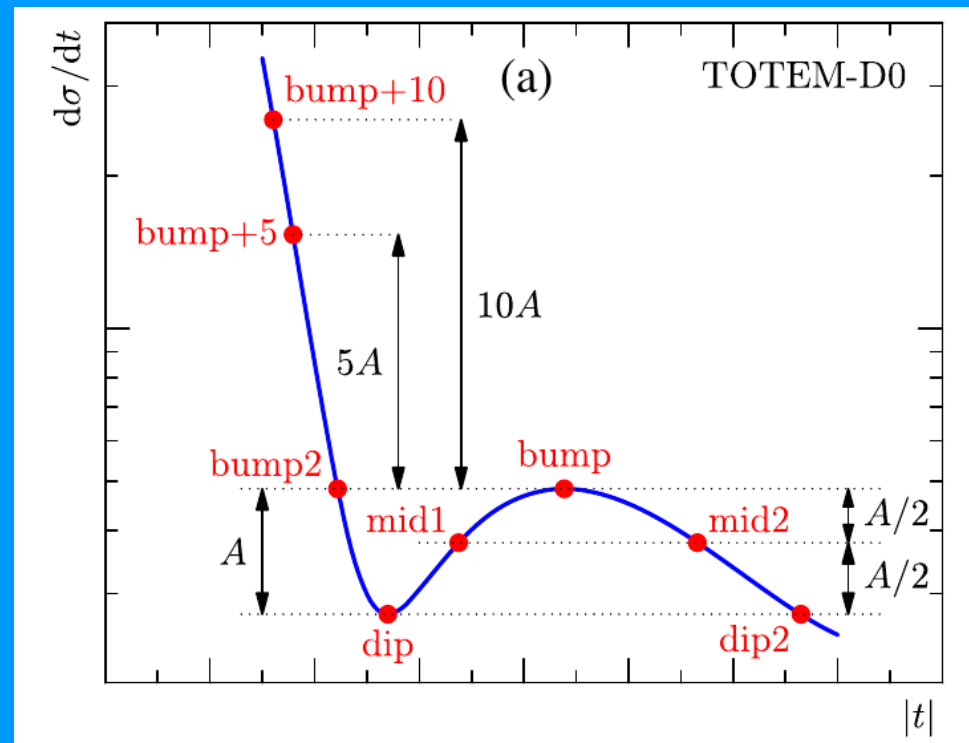

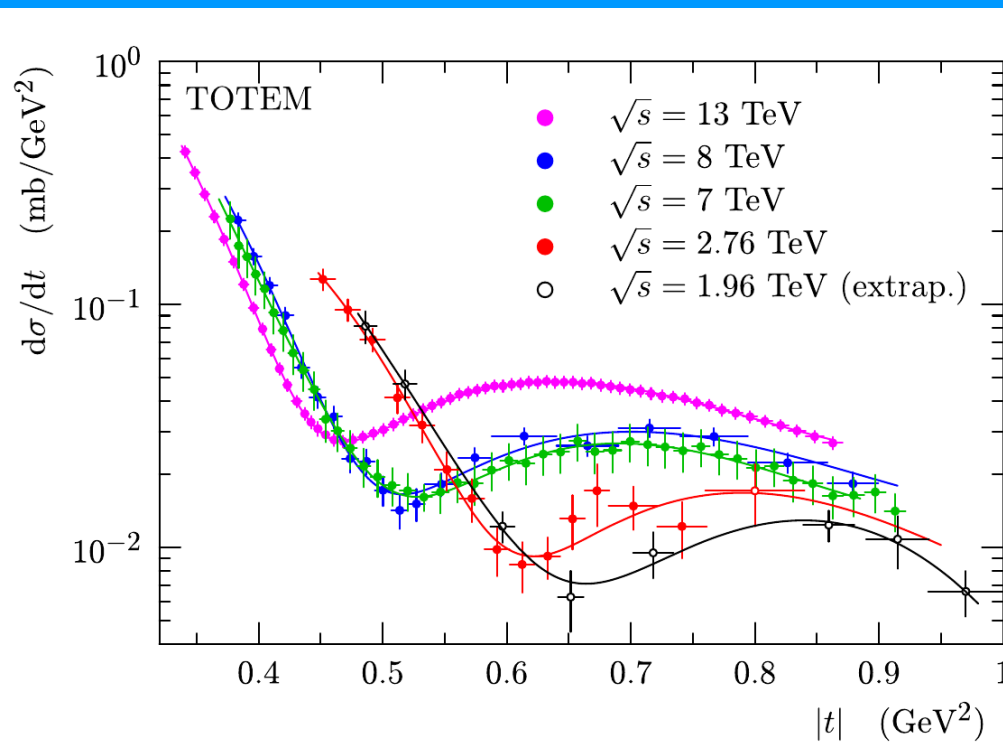

Bialas-Bzdak model

Significant Odderon effects can be extracted in an upward extrapolation from 1.96 TeV ppbar data to 2.76 and 7 TeV pp data

Argument: It depends on the the error bars of data and on the extrapolated data which is different in the two extrapolation directions since the extrapolation uncertainties increase downwards

TOTEM-D0 extrapolation

4 elastic scattering pp data sets at 2.76, 7, 8 and 13 TeV were used to extrapolate to 1.96 TeV pp to be able to compare with 1.96 TeV ppbar data measured by D0 Collaboration. 8 characteristic points were selected in each double exponential fits

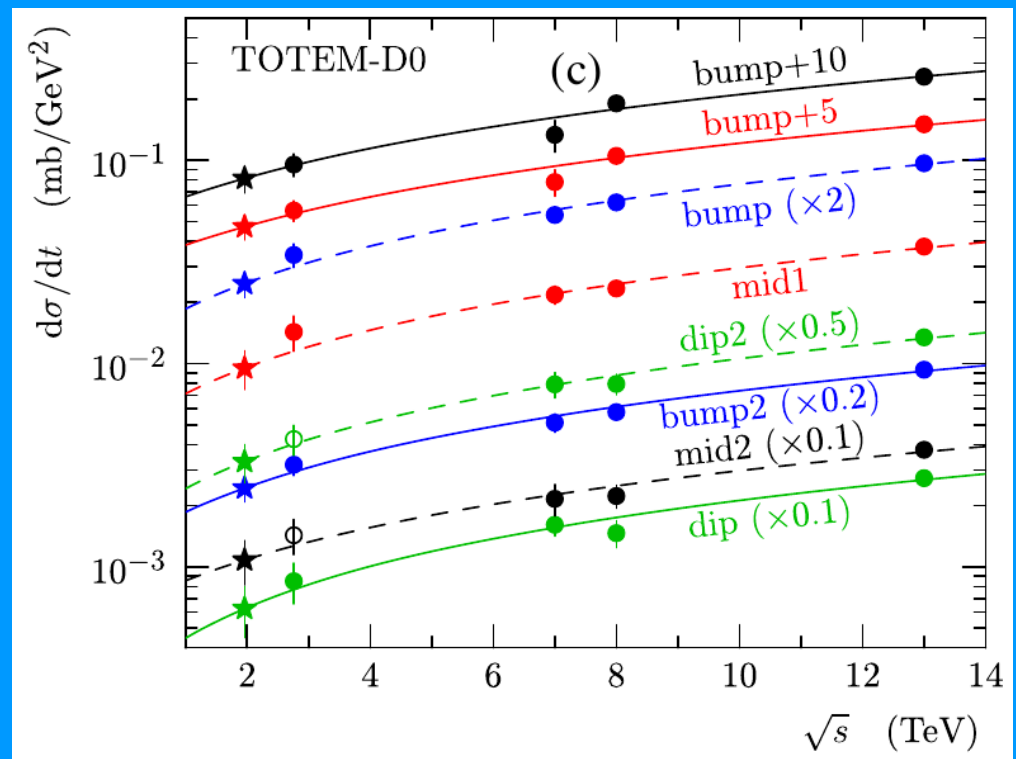

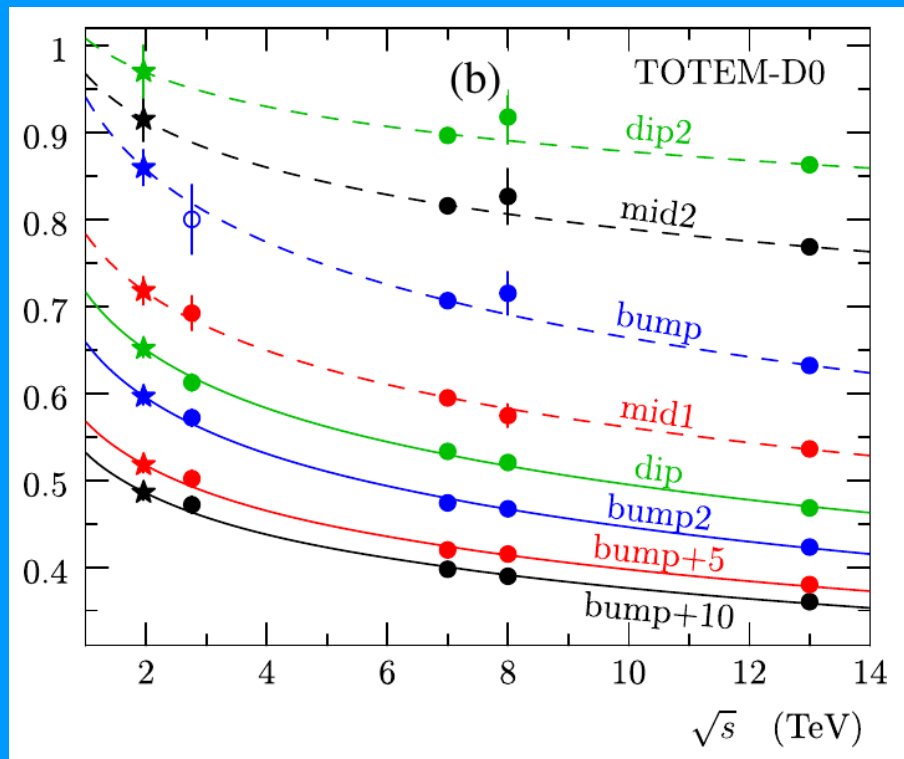

TOTEM-D0 extrapolation

Extrapolations in s are model dependent (sounded at conf.s, too)

Argument: *They are rather parametrizations*

$$|t| = a \log(\sqrt{s}) + b \text{ and } (d\sigma/dt) = c\sqrt{s} + d$$

TOTEM-D0 extrapolation

For normalization, an extrapolation of σ_{tot} 's to 1.96 TeV is model dependent

Argument: It is rather a parametrization

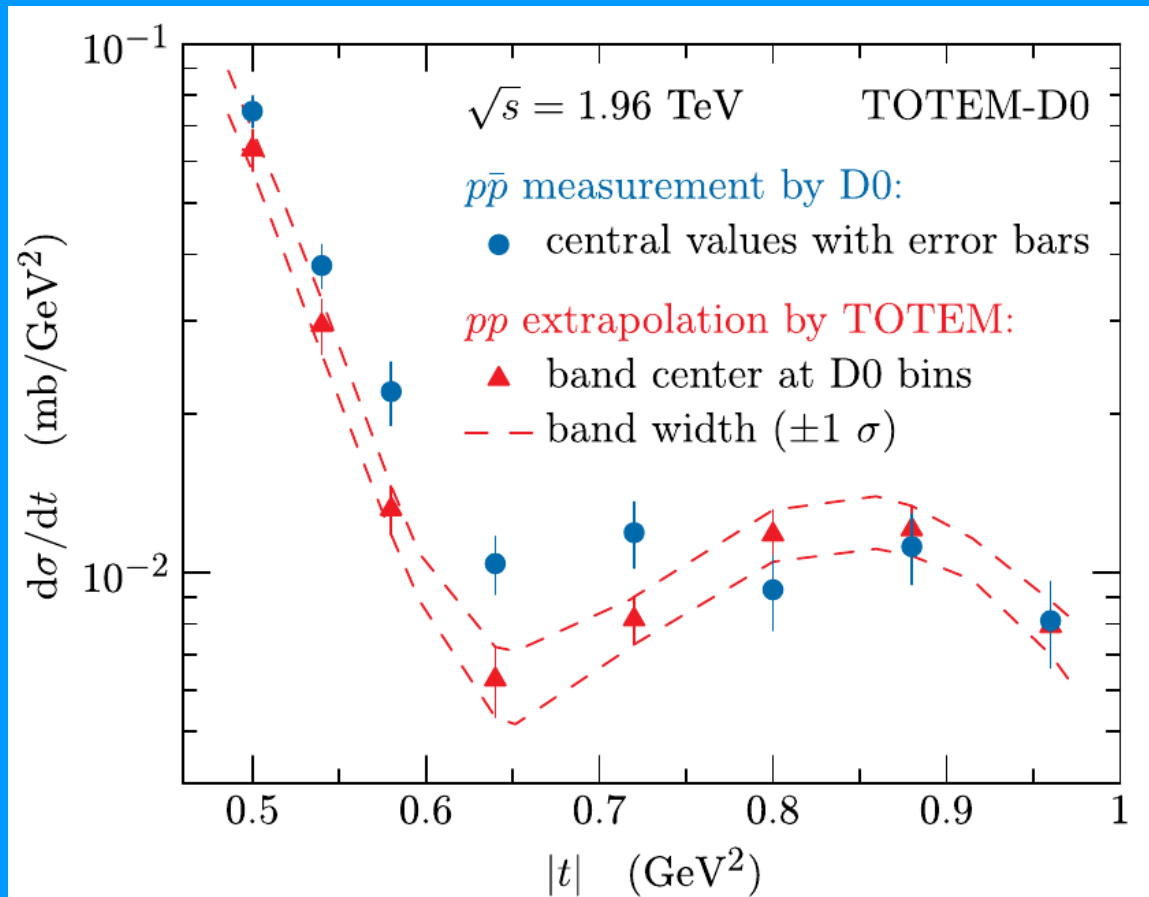

$$\sigma_{\text{tot}}^2 = \frac{16\pi(\hbar c)^2}{1 + \rho^2} \left(\frac{d\sigma}{dt} (t = 0) \right)$$

$$\sigma_{\text{tot}} = b_1 \log^2(\sqrt{s}/1 \text{ TeV}) + b_2 \quad (2)$$

gives $\sigma_{\text{tot}}^{pp}(1.96 \text{ TeV}) = 82.7 \pm 3.1 \text{ mb}$ [43]. The extrapolated cross section is converted to a differential cross section $d\sigma/dt = 357 \pm 26 \text{ mb/GeV}^2$ at $t = 0$ using the optical theorem

TOTEM-D0 extrapolation

The equality of Optical Points at $-t = 0$ of the two 1.96 TeV data sets (pp and ppbar) is an assumption. In the ref. it is asymptotical

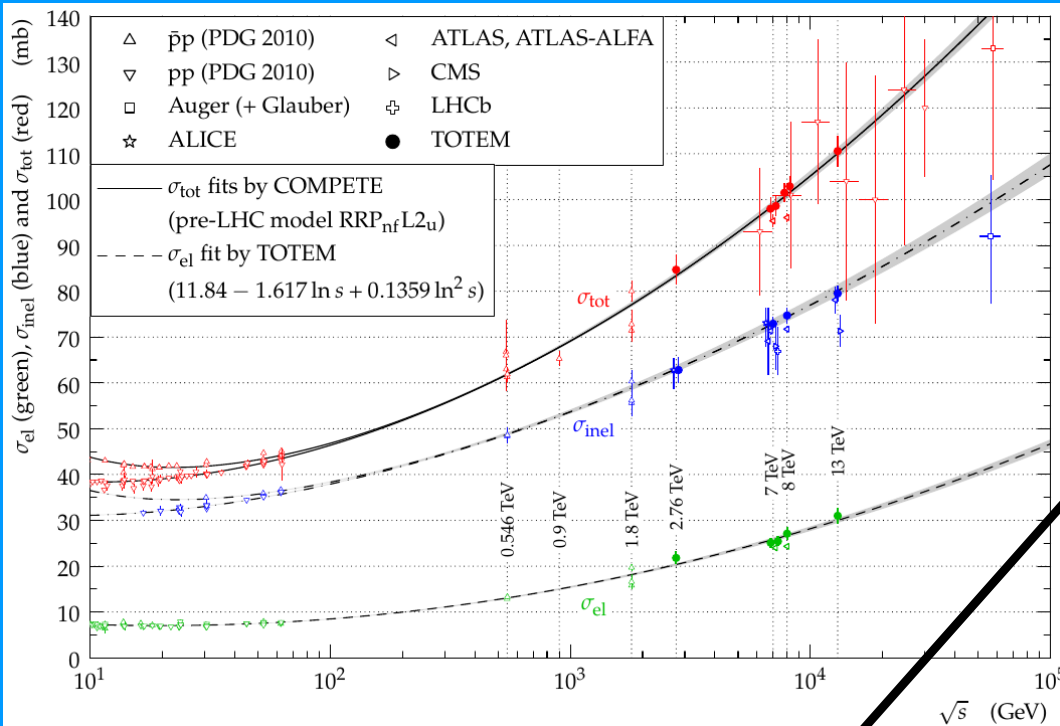

Argument: *we are in the asymptotical region of energies*

TOTEM-D0 extrapolation

In all other TOTEM publications σ_{tot} 's are fitted by

$$a + b \ln(s) + c \ln^2(s).$$

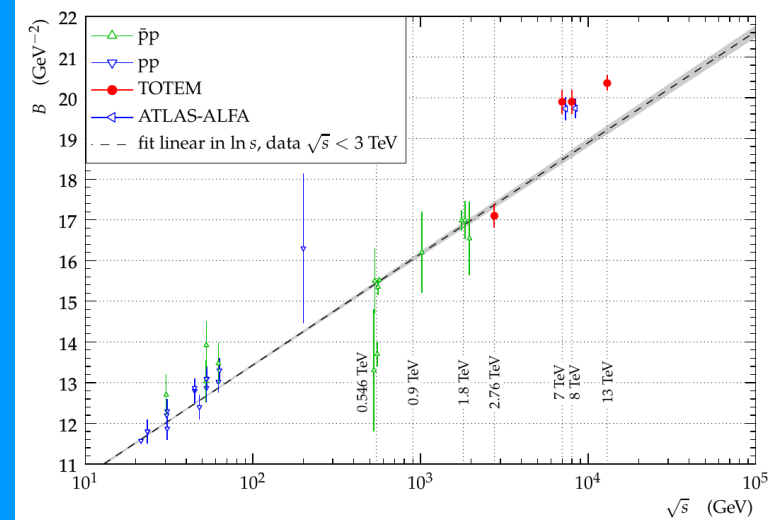

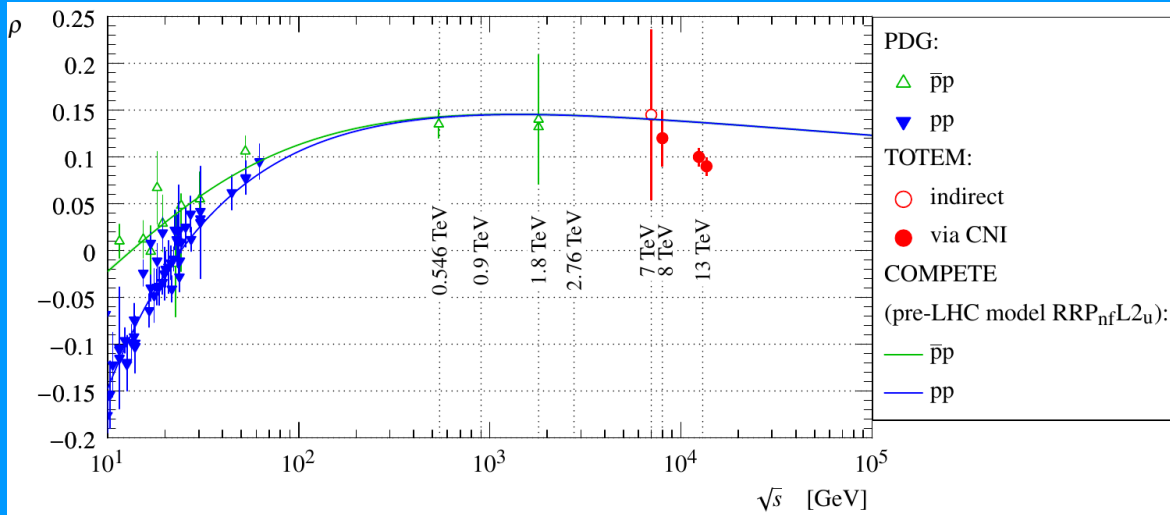

The σ_{tot} 's obtained by the two different fits are contradictory

H(x) scaling of recent 8 TeV elastic pp data

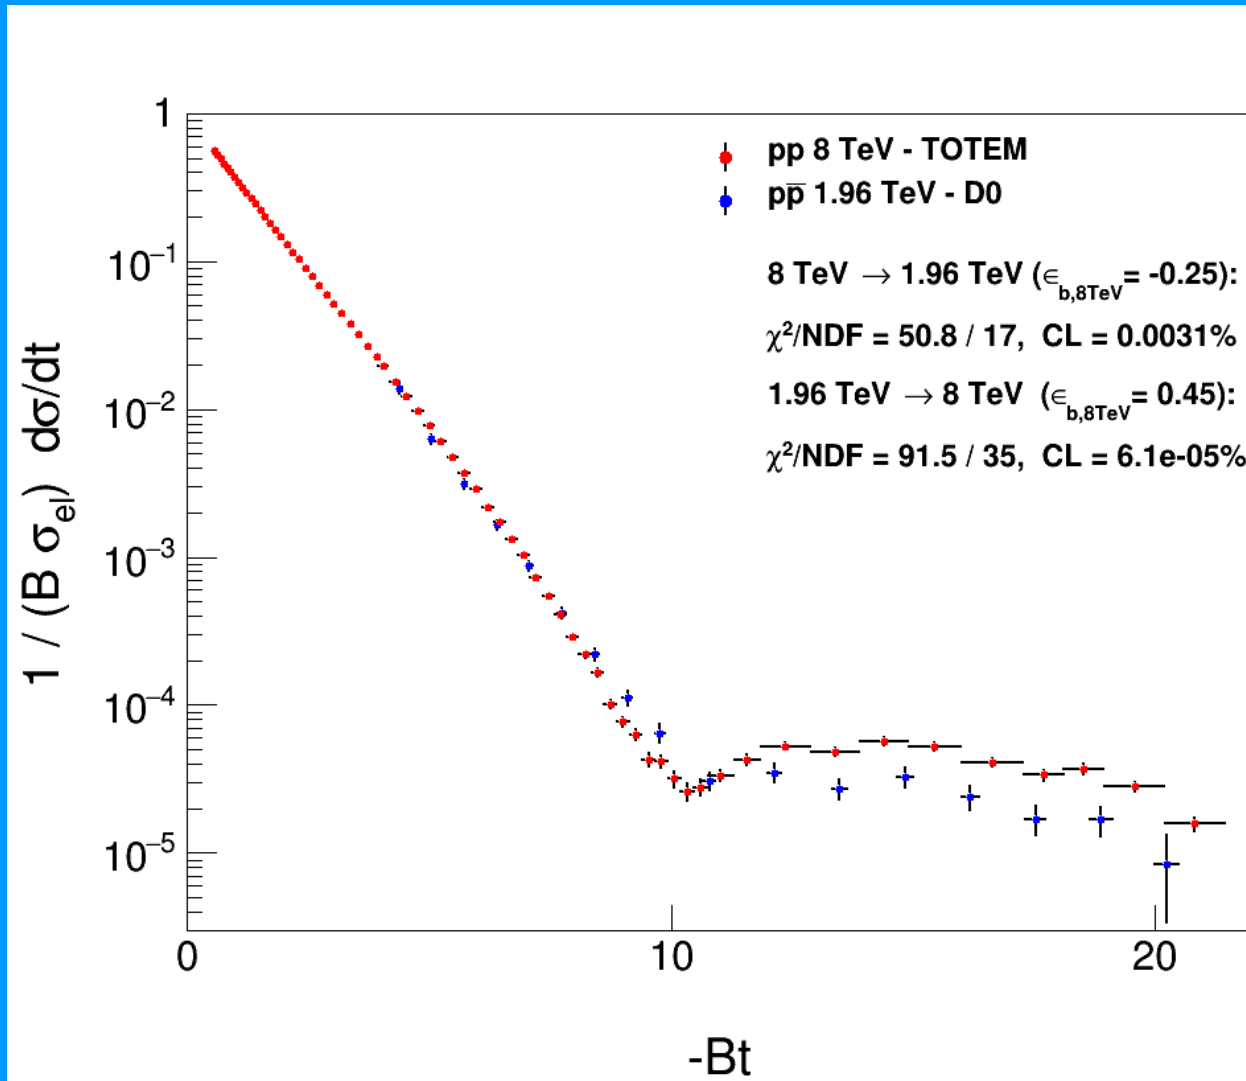

Significance of
deviation in standard
deviation to 7TeV:

$$\sigma_{\min} = 0.18$$

With more realistic
half-size x error bins:

$$\sigma_{\min,} = 1.69$$

H(x) scaling of recent 8 TeV elastic pp data

Significance to 1.96
ppbar data:

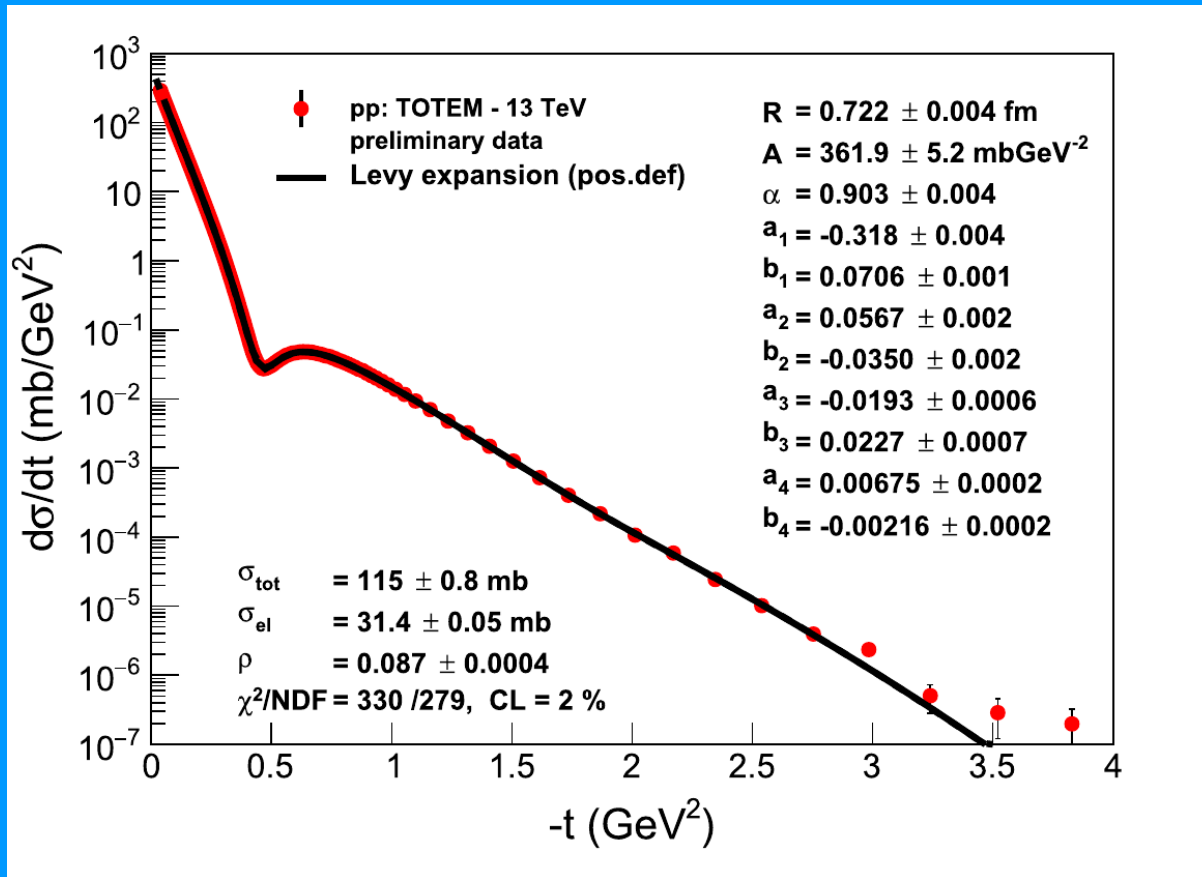

$$\sigma_{\min} = 4.16$$

With more realistic
half-size x error bins:

$$\sigma_{\min,} = 5.21$$

Old Levy description of elastic pp data

Example of model independent orthonormal Levy parametrization
up to 4th order *EPJC (2019) , 79:62*

New Levy description of elastic pp data (preliminary)

Based on Phillips-Barger model (succesful in limited $-t$ and s regions), *Phys.Lett* 46B (1973) :

$$\frac{d\sigma}{dt} = |A_1 + A_2|^2 = |A e^{-Bt} + e^{-i\Phi t} C e^{-Dt}|^2$$

Generalized Phillips-Barger model by orthonormal Levy series:

$$\frac{d\sigma}{dt} = \left| e^{-(R_1^2 t)^{\alpha_1}/2} \sum_{j=0}^{\infty} c_{1j} l_j + e^{-(R_2^2 t)^{\alpha_2}/2} \sum_{j=0}^{\infty} c_{2j} l_j \right|^2$$

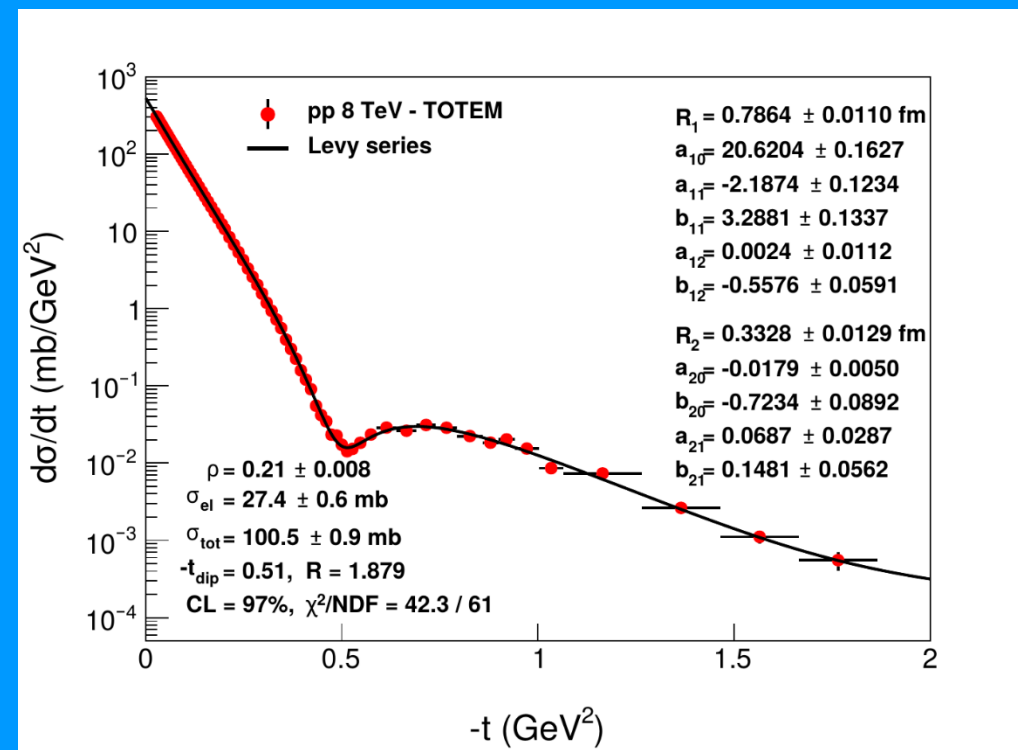

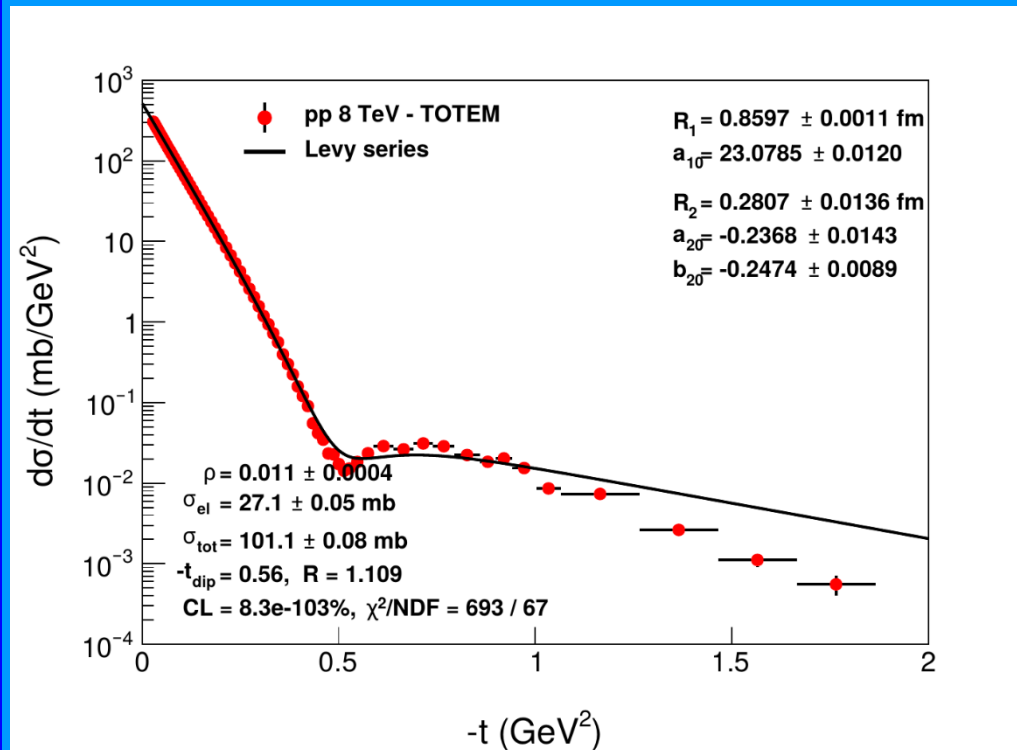

where $l_j(R^2 t, \alpha)$ are the Levy orthonormal polynomials
and $c_j = a_j + ib_j$

New Levy description of elastic pp data (preliminary)

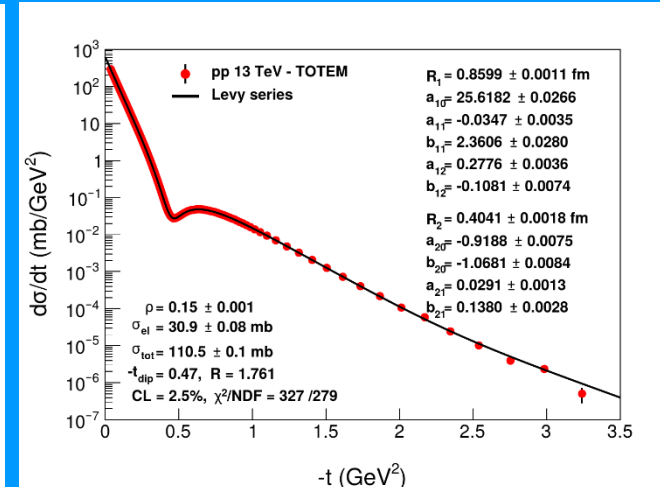

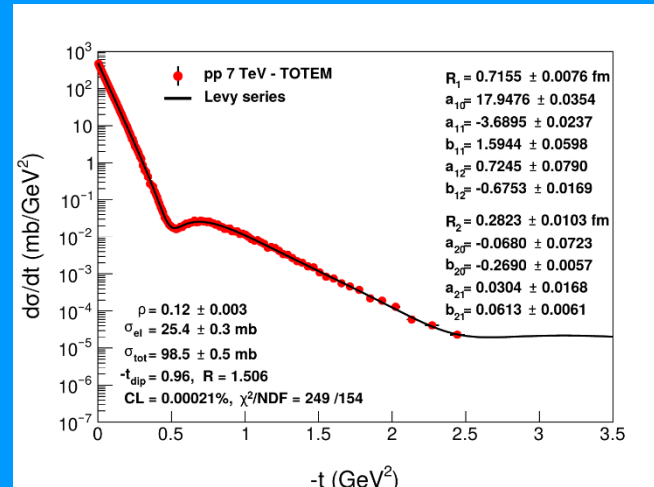

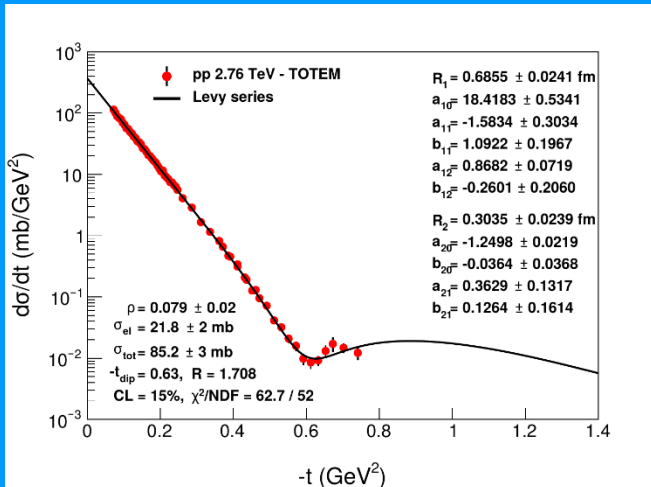

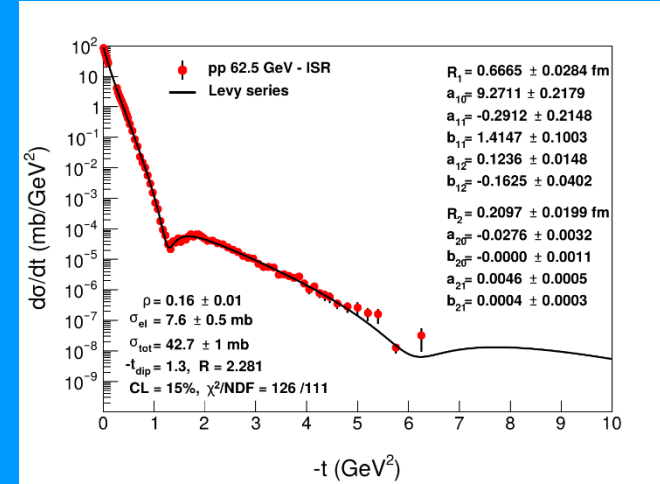

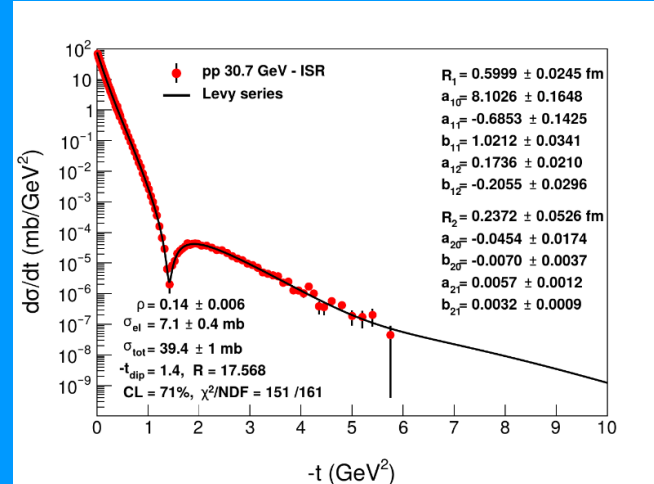

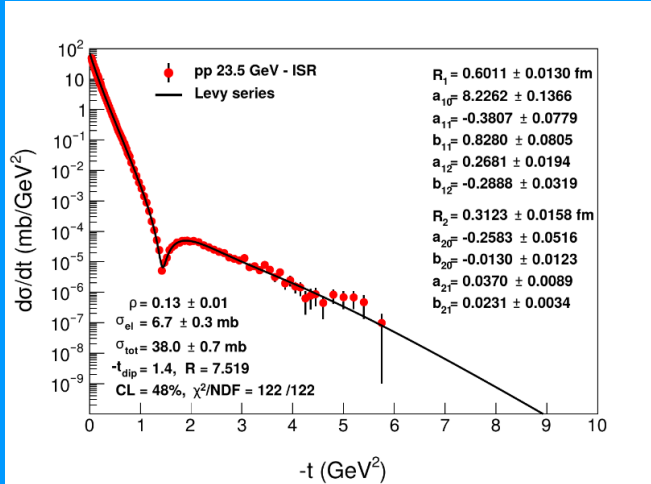

Motivation: description of pp scattering data for the full coverage of the ppbar 1.96 TeV acceptance

Phillips-Barger

Levy generalized Phillips-Barger

New Levy description of elastic pp data (preliminary)

New Levy description of elastic pp data (preliminary)

Preliminary approximate values for the half spatial parameters ($R_1/2$) and ratios (R_1/R_2) (without error estimations):

23 GeV:	0.30 fm ,	1.92
30 GeV:	0.30 fm,	2.53
62 GeV:	0.33 fm,	3.18
2.76 TeV:	0.34 fm,	2.26
7 TeV:	0.36 fm,	2.54
8 TeV:	0.39 fm,	2.36
13 TeV:	0.43 fm,	2.13

The half extension values coincide with earlier assumed hard core nucleon radii (~ 0.40 fm) set in Glauber and DIPSY dipole simulations. It might reflect nucleon and di-quark type scattering

Conclusion

Published Odderon results have been critically scrutinised

Assumptions and conditions with possible influence on results were shown and investigated in each of the 3 different methods

Newly released 8 TeV data confirm the Odderon signal via $H(x)$ scaling

New Levy type expansion method was introduced to describe elastic pp and ppbar scattering data for possible extrapolation to 1.96 TeV pp differential cross-section
