SHYAM BALAJI

STELLAR LIMITS ON A LIGHT SCALAR

In collaboration with: P.S.B. Dev, Y. Zhang and J. Silk [arxiv: 2205.01669] accepted for publication with JCAP

December 6, 2022

MOTIVATION

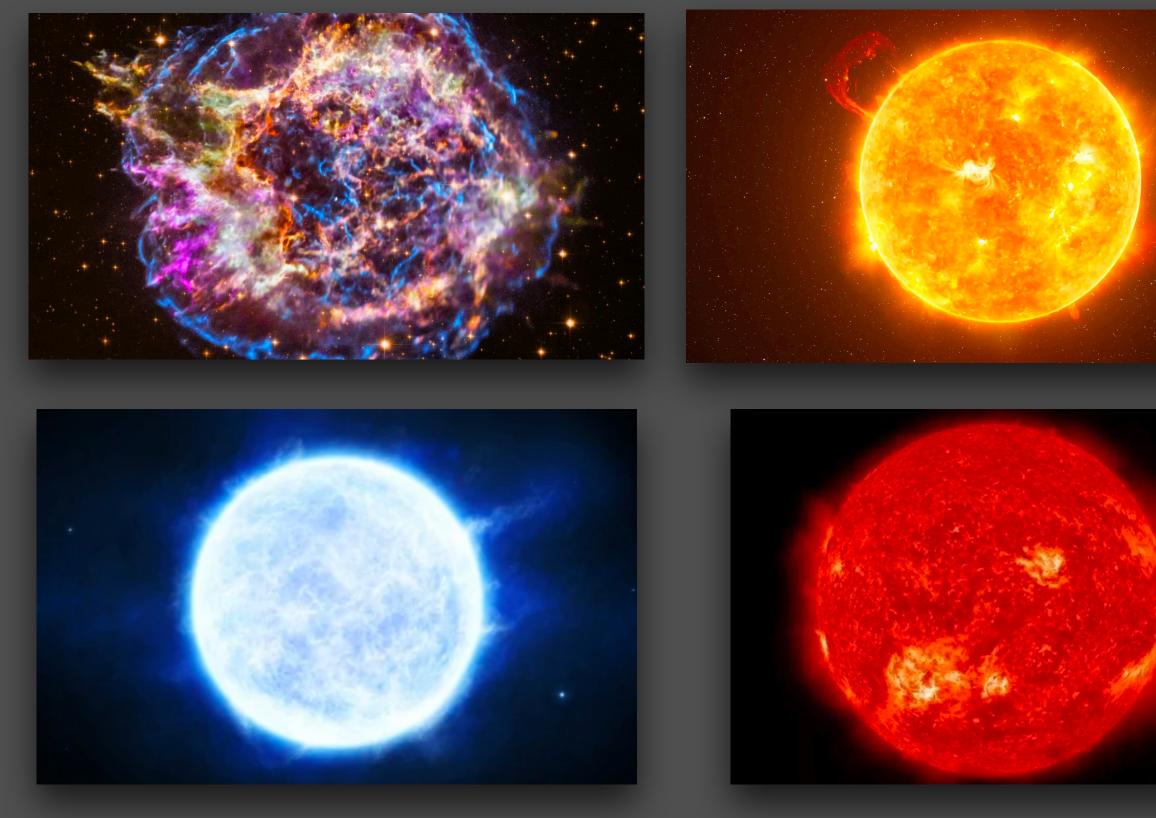

• Supernovae (SN) and stars provide a unique environment to copiously produce light hypothetical particles: axions/ALPs, dark photon, heavy neutrino, compact extra dimensions, *CP*-even scalar

• Raffelt criterion: the energy loss due to these exotic particles cannot exceed that from the measured neutrino emission as this would reduce the cooling time of the SN to less than what is observed

• Very limited SN limits in the literature on light *CP*-even scalar (compared to axion/ALP & dark photon)

Motivation for a scalar singlet

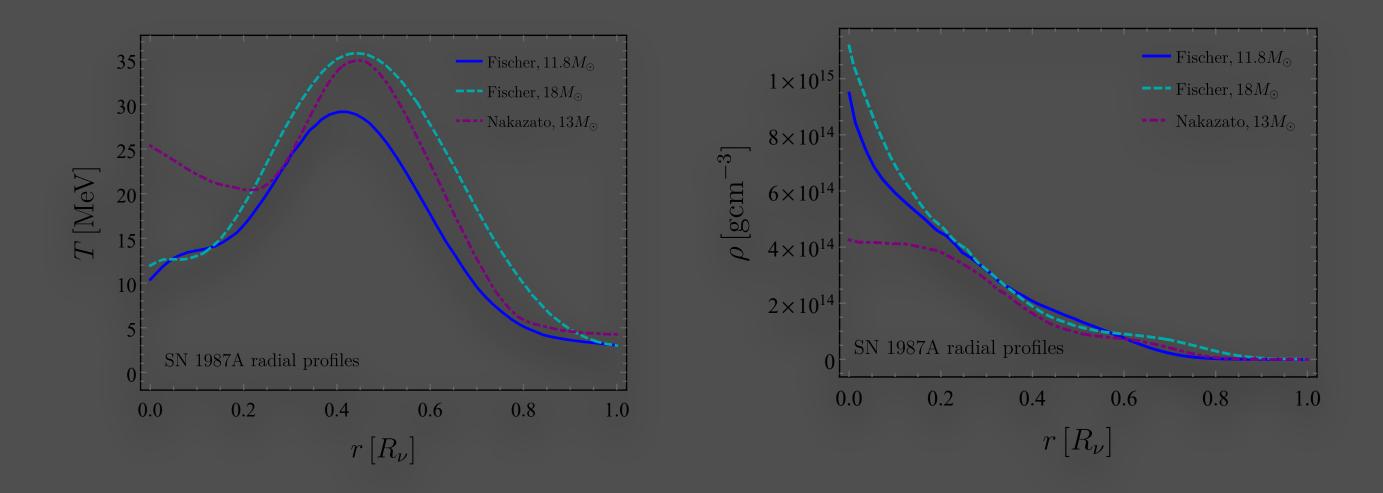

- Stabilise the SM vacuum
- Address the hierarchy problem in relaxion models
- Generate the baryon asymmetry via baryogenesis
- Address the cosmological constant problem
- Mediate the interaction between DM and the SM particles
- S with mass at the keV scale, can also play the role of light DM

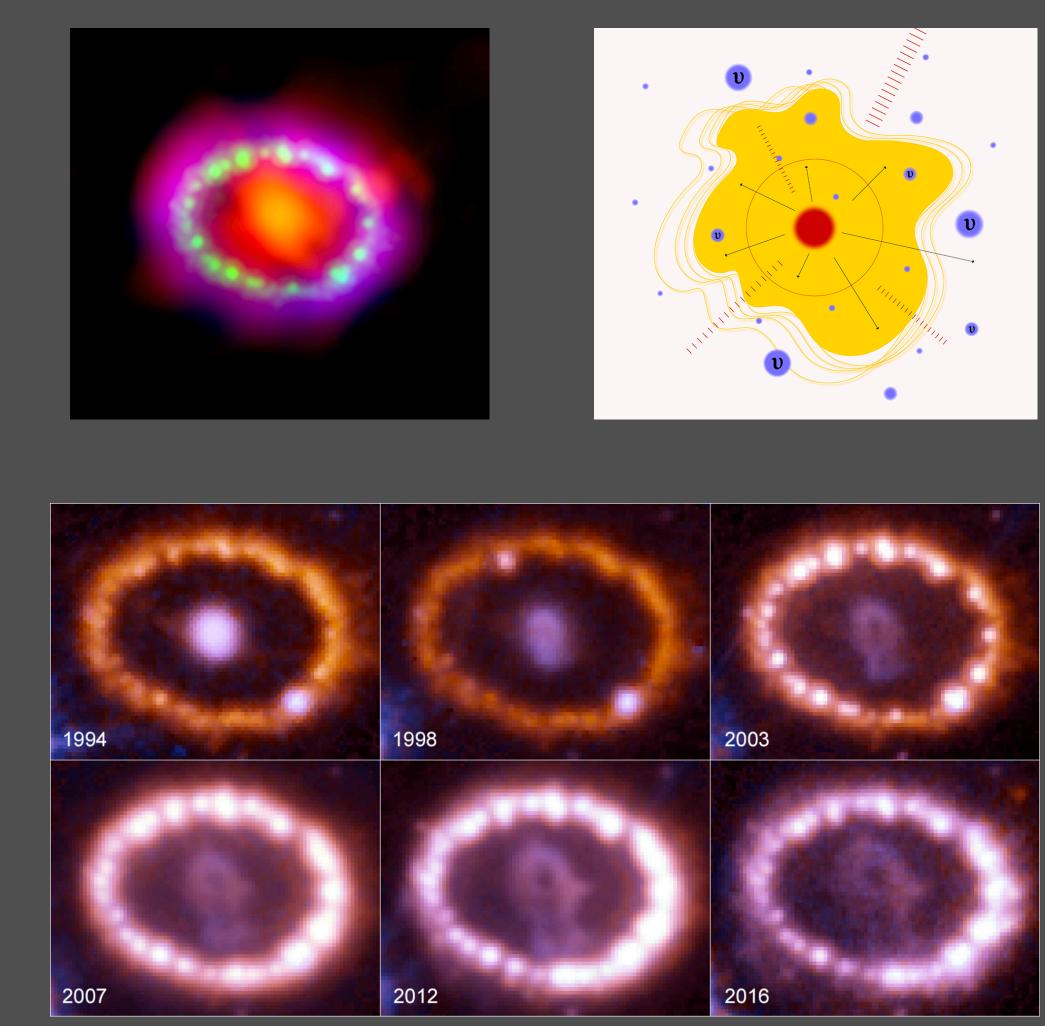

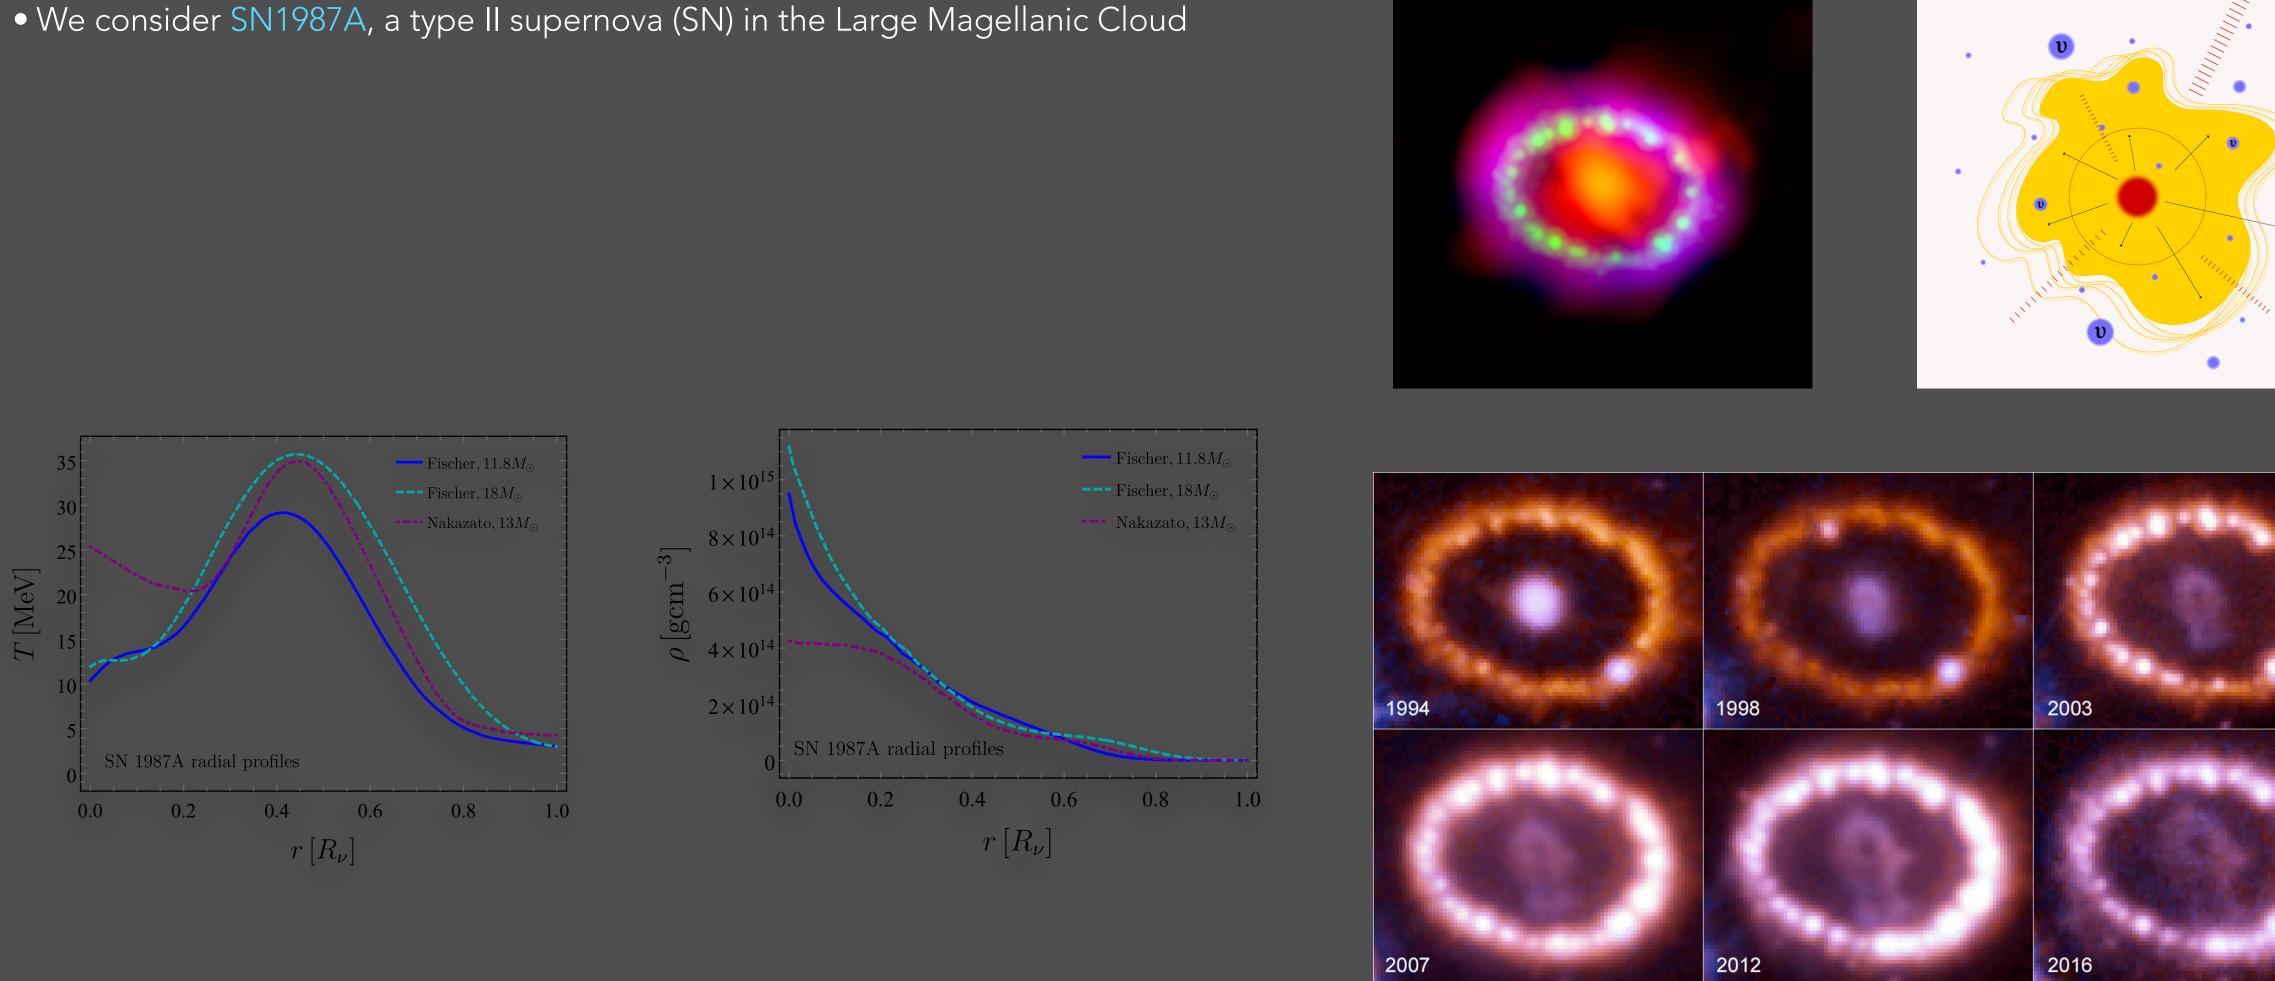

Shyam Balaji

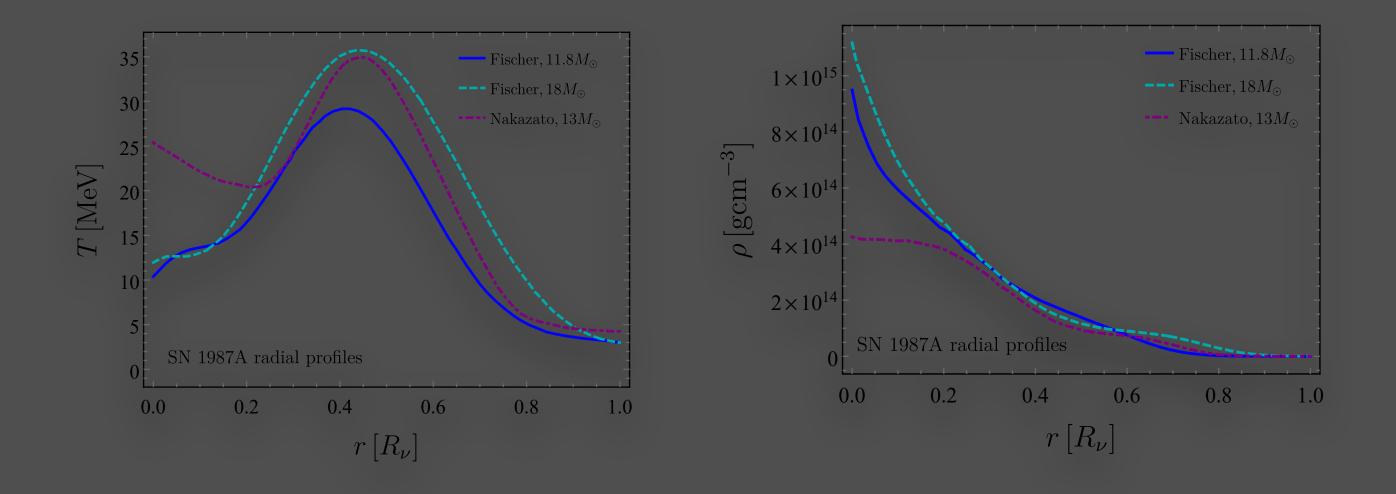

Shyam Balaji

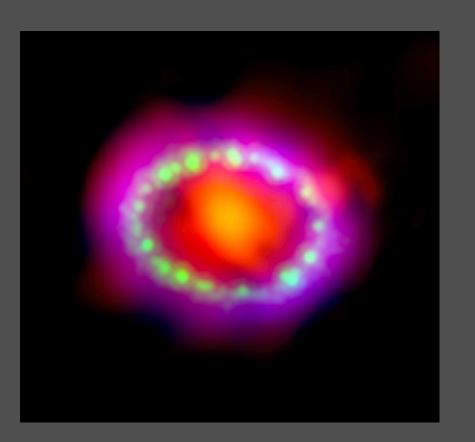

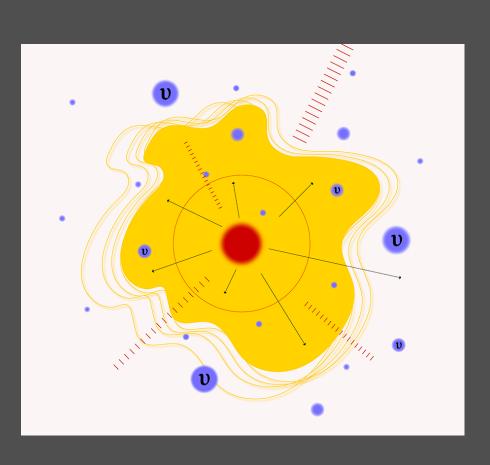

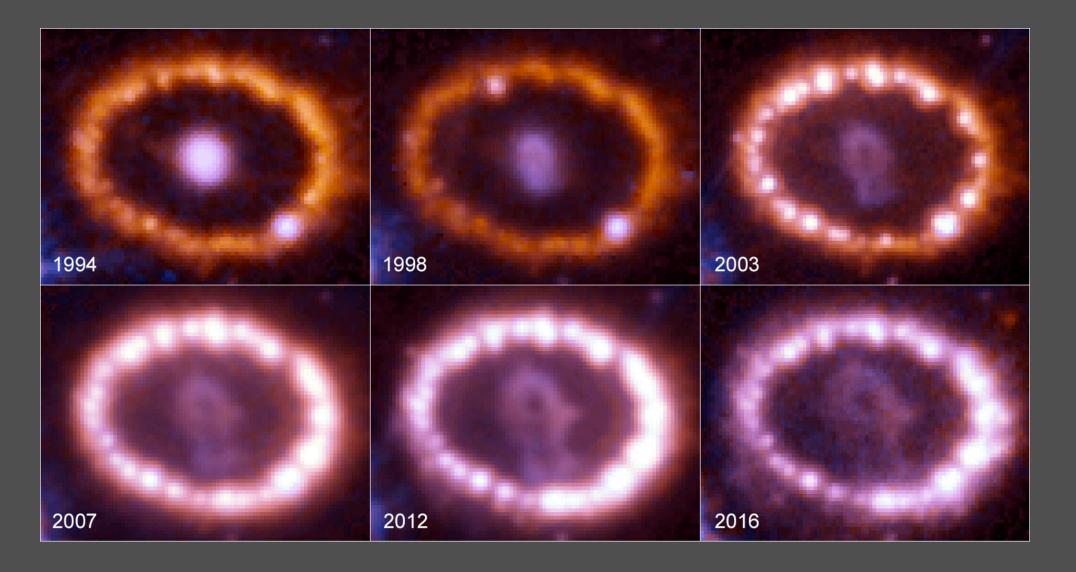

- We consider SN1987A, a type II supernova (SN) in the Large Magellanic Cloud
- Neutrino emission happens just before core collapse but before visible light is emitted

Shyam Balaji

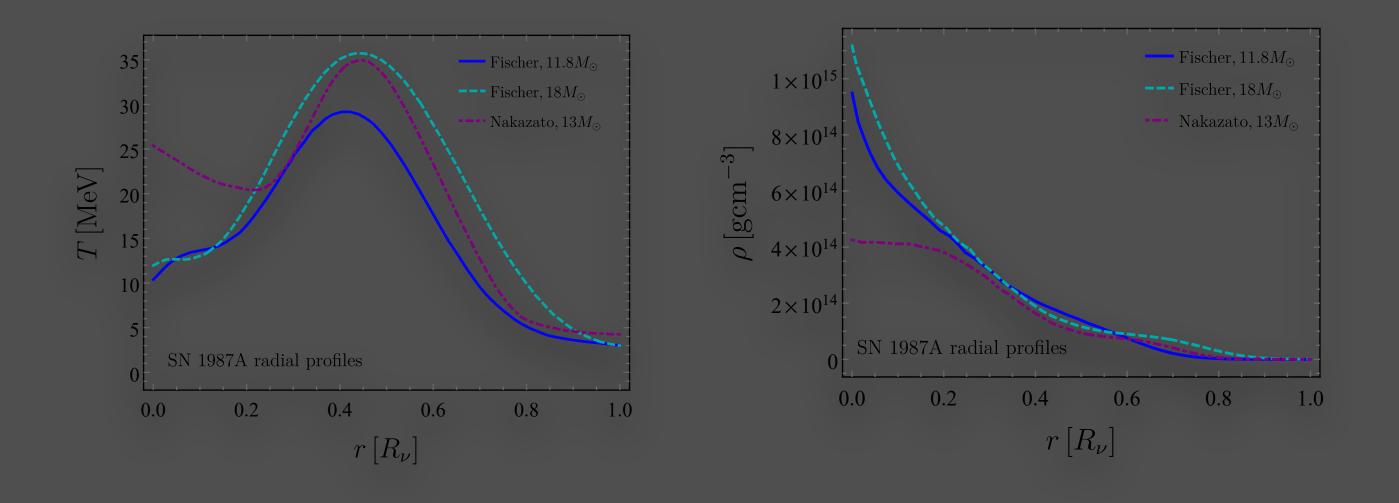

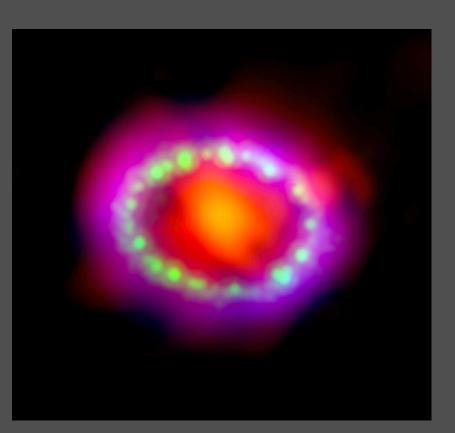

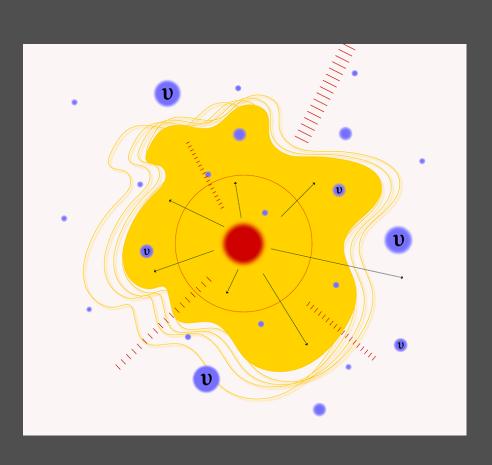

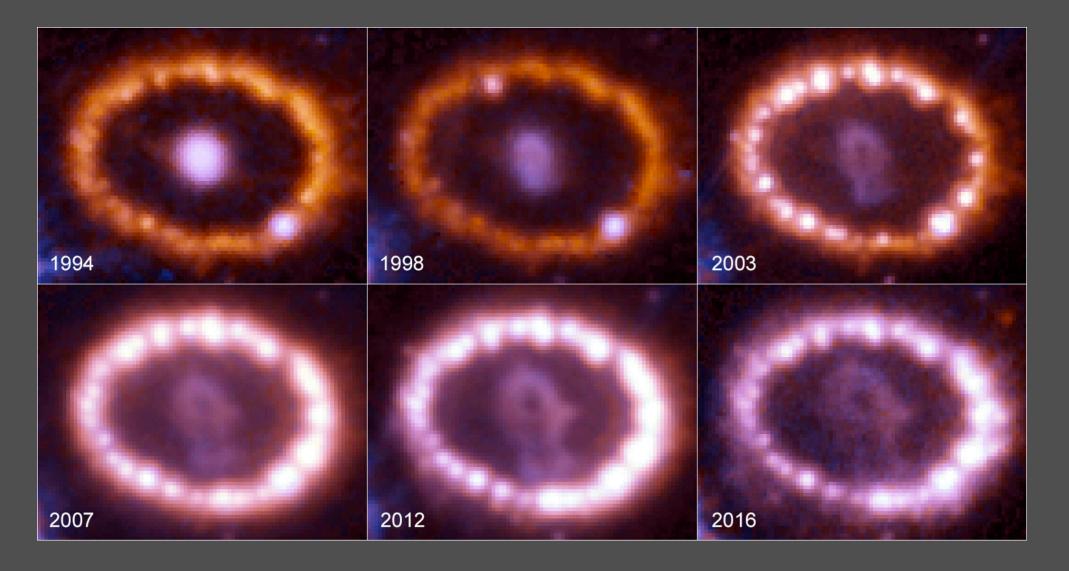

- We consider SN1987A, a type II supernova (SN) in the Large Magellanic Cloud
- Neutrino emission happens just before core collapse but before visible light is emitted
- We use SN1987A to set limits because it has well established neutrino luminosity

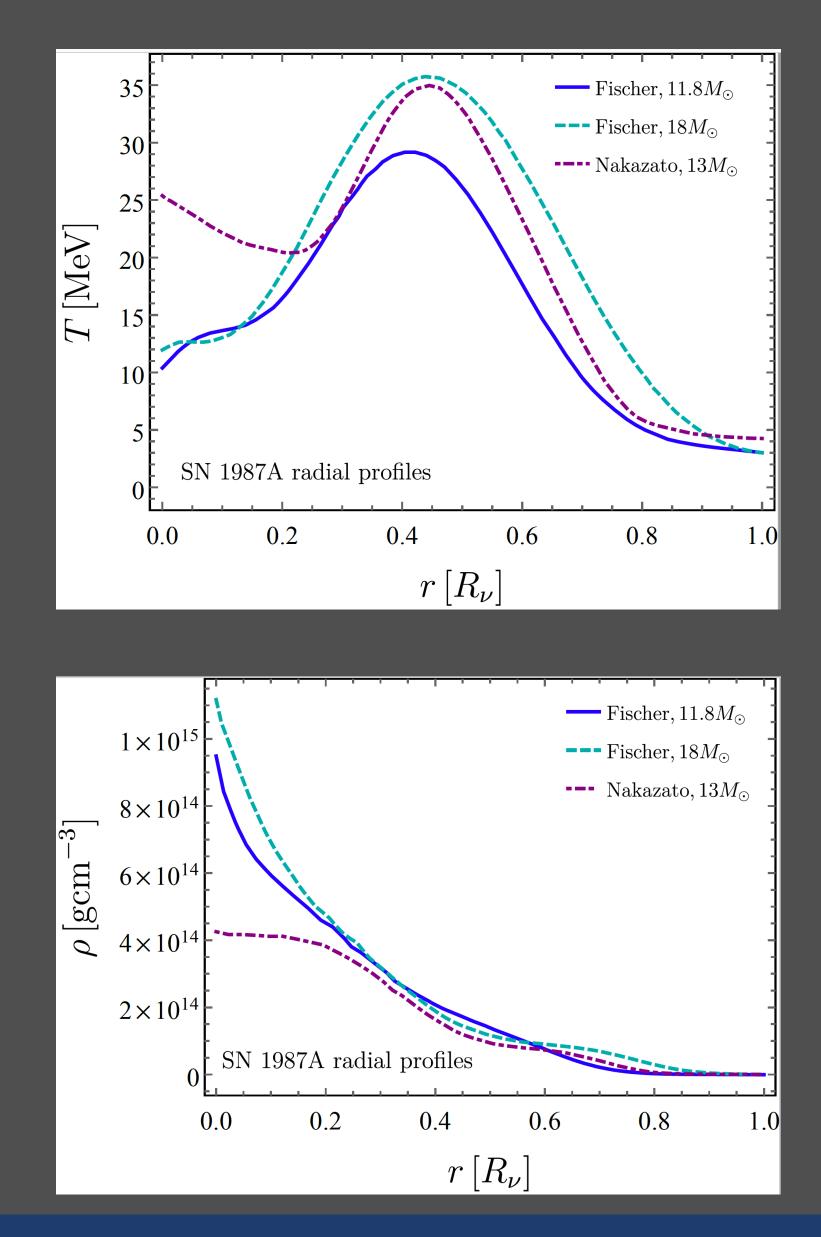

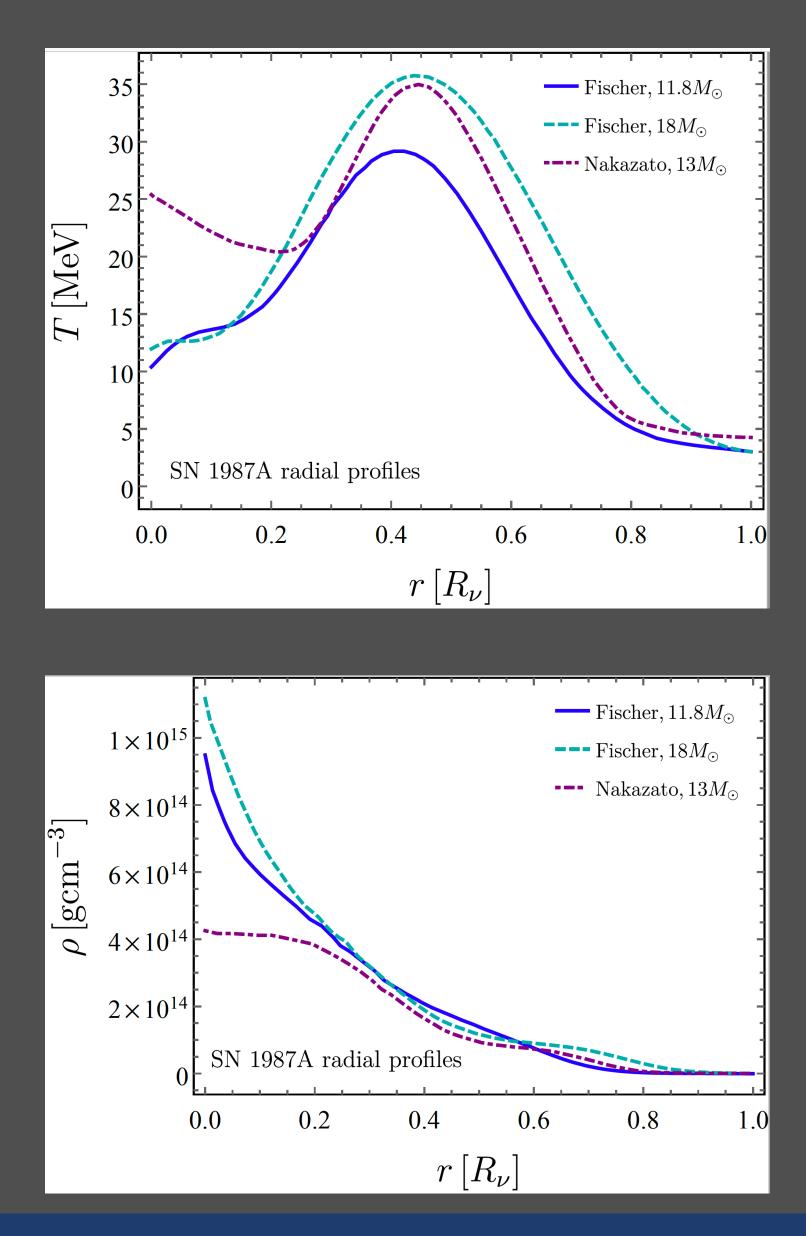

Shyam Balaji

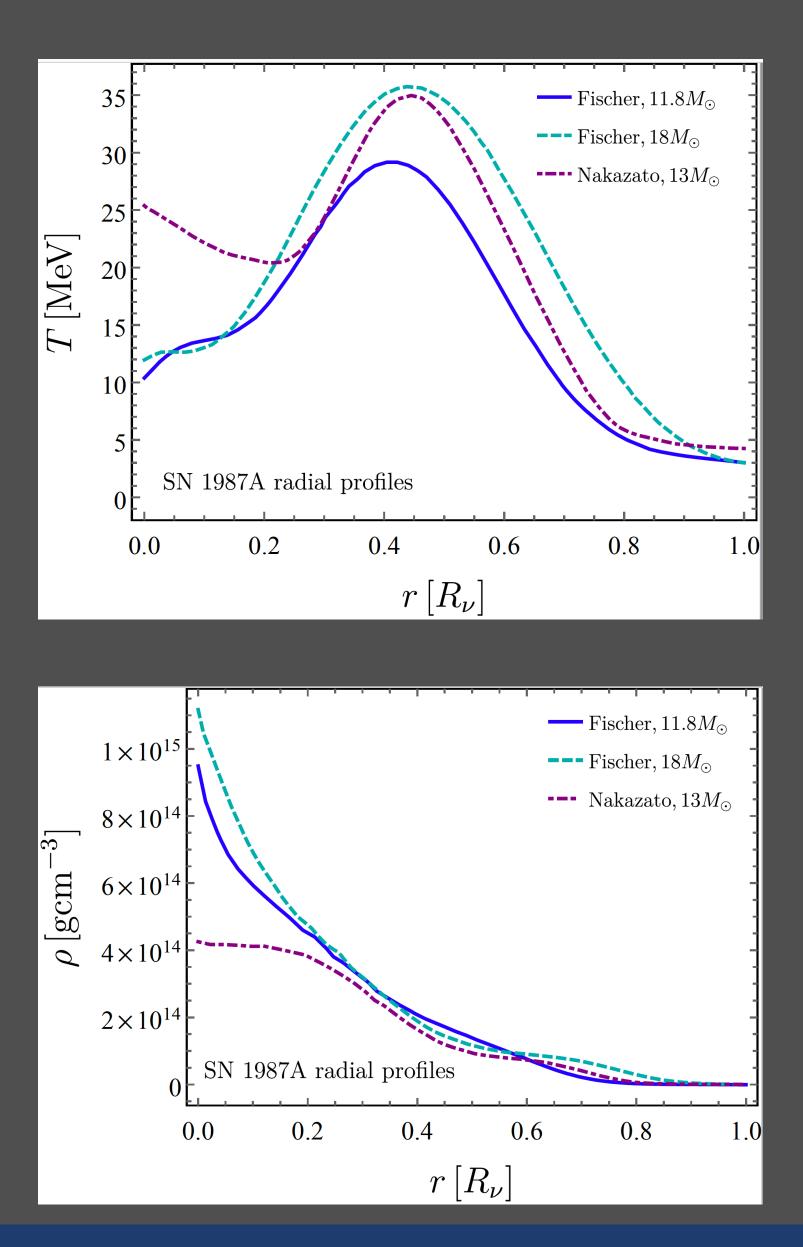

• SN1987A is an excellent candidate for examining new physics models because of the combination of the unique physical conditions attained in the star and the proximity of the explosion to our solar system.

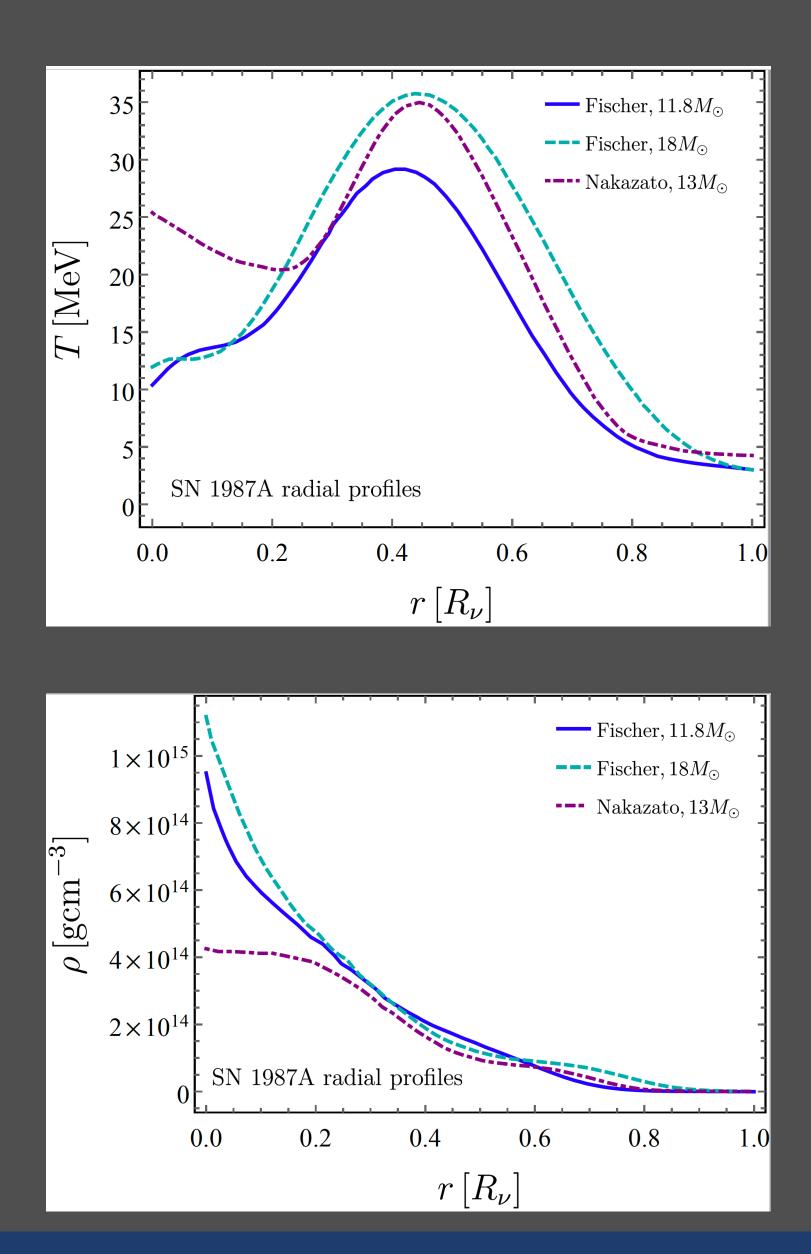

- SN1987A is an excellent candidate for examining new physics models because of the combination of the unique physical conditions attained in the star and the proximity of the explosion to our solar system.
- Despite this, constraints on new physics from SN1987A are inherently limited due to the difficulties associated with understanding the detailed physical processes of the supernova, even in the case without BSM physics.

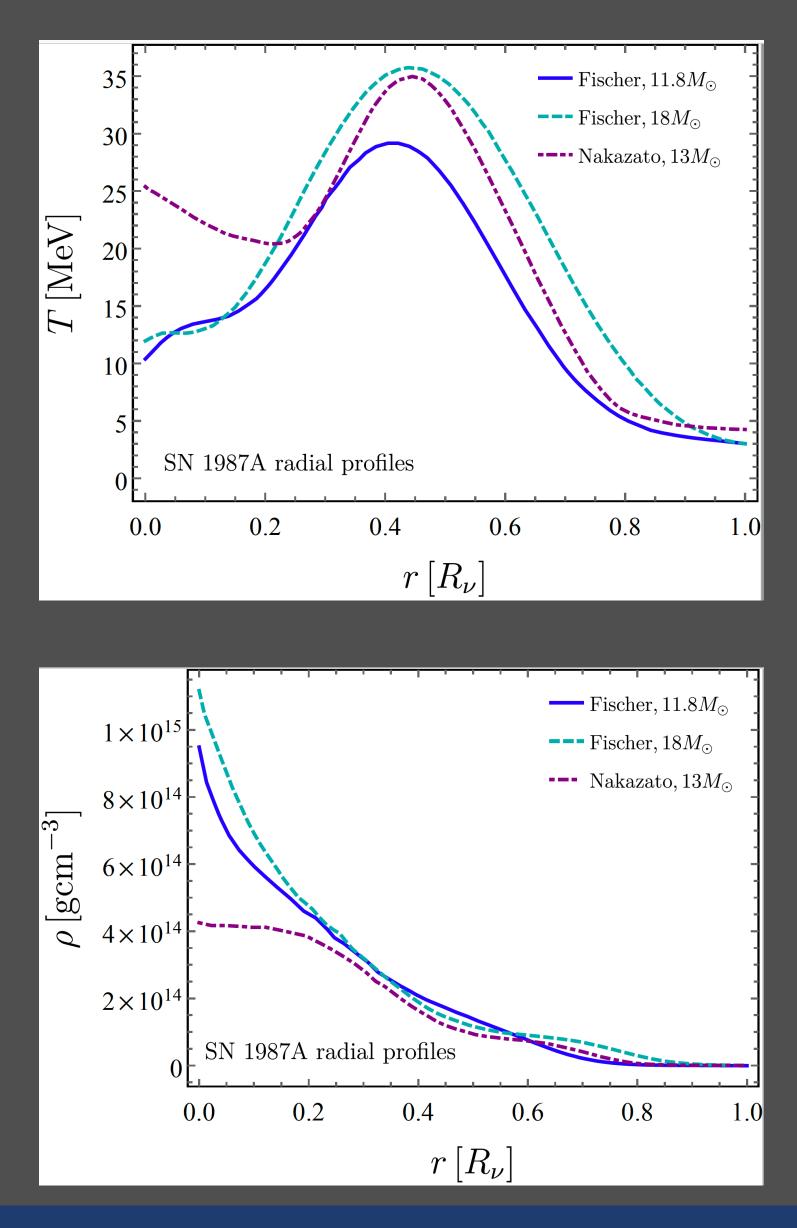

- SN1987A is an excellent candidate for examining new physics models because of the combination of the unique physical conditions attained in the star and the proximity of the explosion to our solar system.
- Despite this, constraints on new physics from SN1987A are inherently limited due to the difficulties associated with understanding the detailed physical processes of the supernova, even in the case without BSM physics.
- The main challenge in using SN1987A to constrain new physics is due to uncertainty surrounding the nature of the progenitor proto-neutron star which comprises the primary driver of the "shock revival" required to sustain the ultimate explosion.

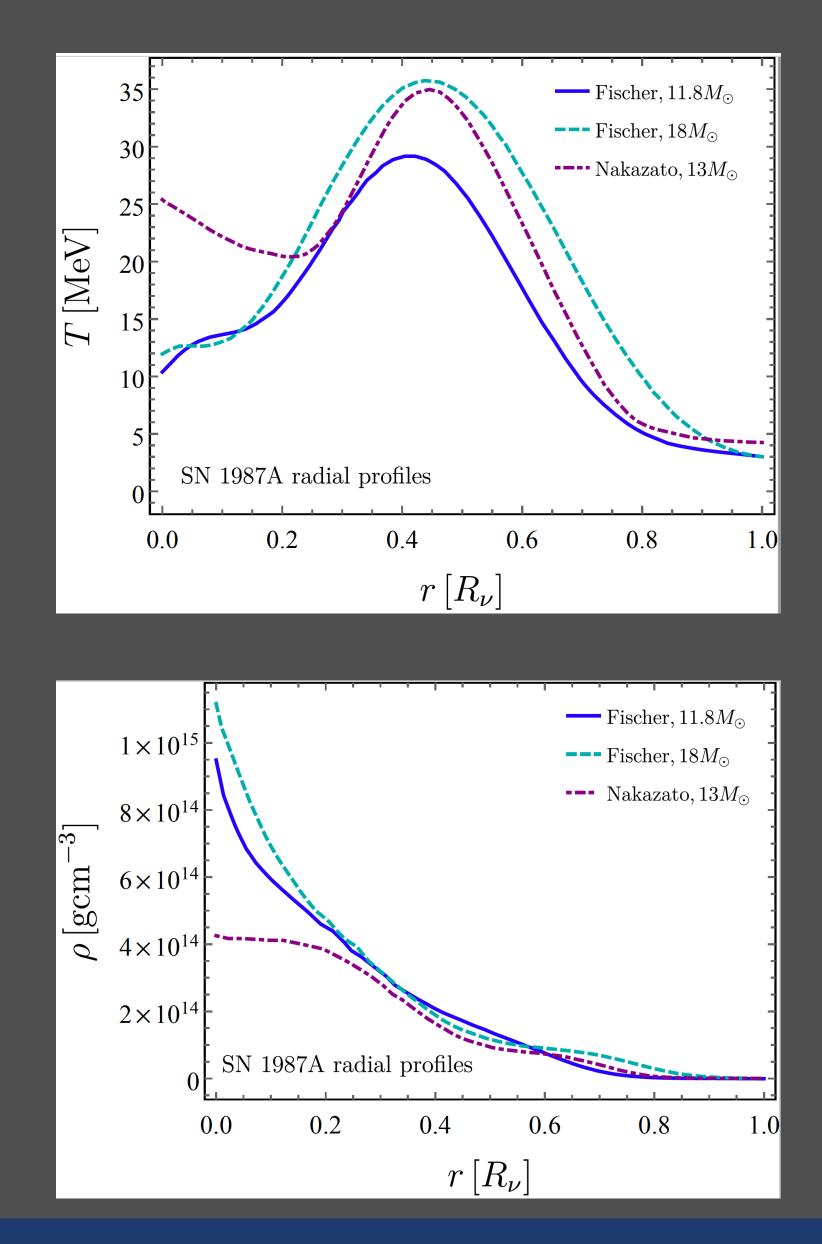

- SN1987A is an excellent candidate for examining new physics models because of the combination of the unique physical conditions attained in the star and the proximity of the explosion to our solar system.
- Despite this, constraints on new physics from SN1987A are inherently limited due to the difficulties associated with understanding the detailed physical processes of the supernova, even in the case without BSM physics.
- The main challenge in using SN1987A to constrain new physics is due to uncertainty surrounding the nature of the progenitor proto-neutron star which comprises the primary driver of the "shock revival" required to sustain the ultimate explosion.
- The mass of the progenitor star is uncertain up to a factor of two, and consequently the temperature and density profiles have large, qualitative uncertainties

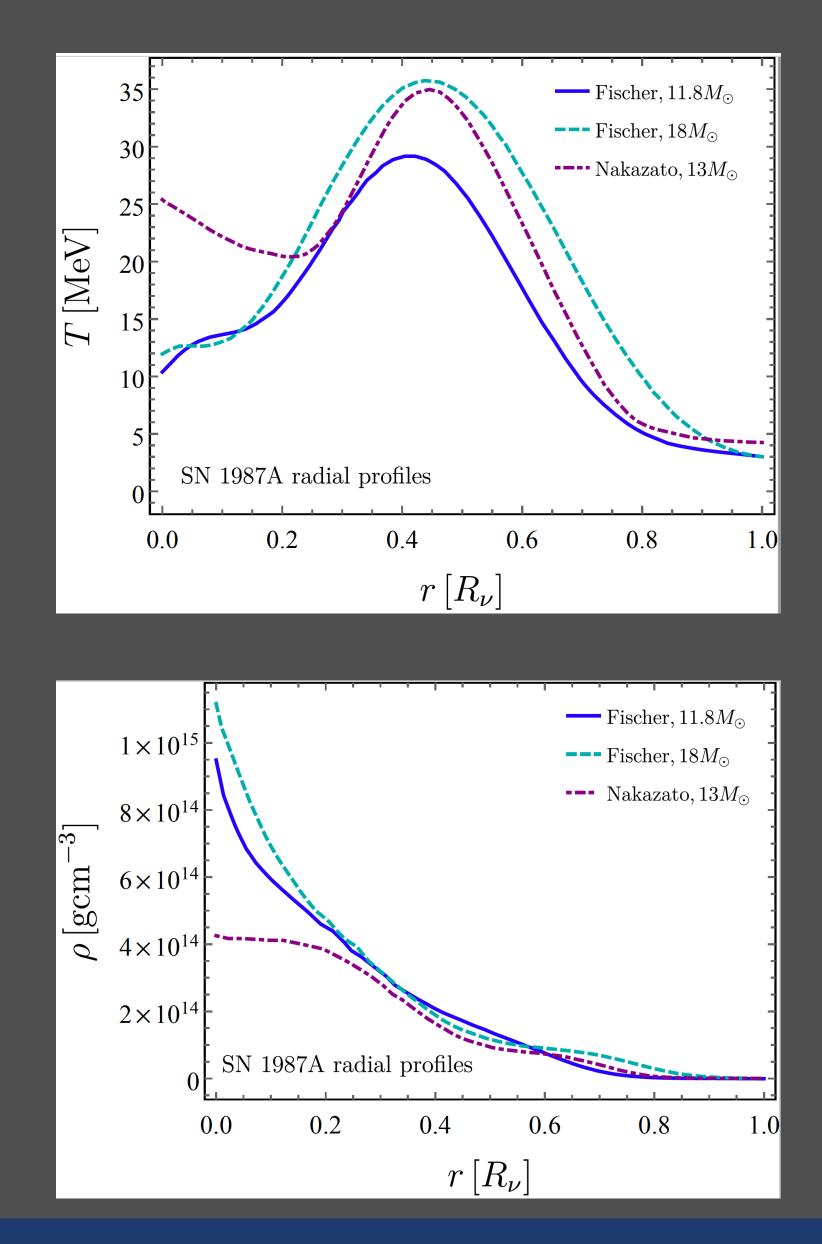

Shyam Balaji

•We adopt the numerical profiles

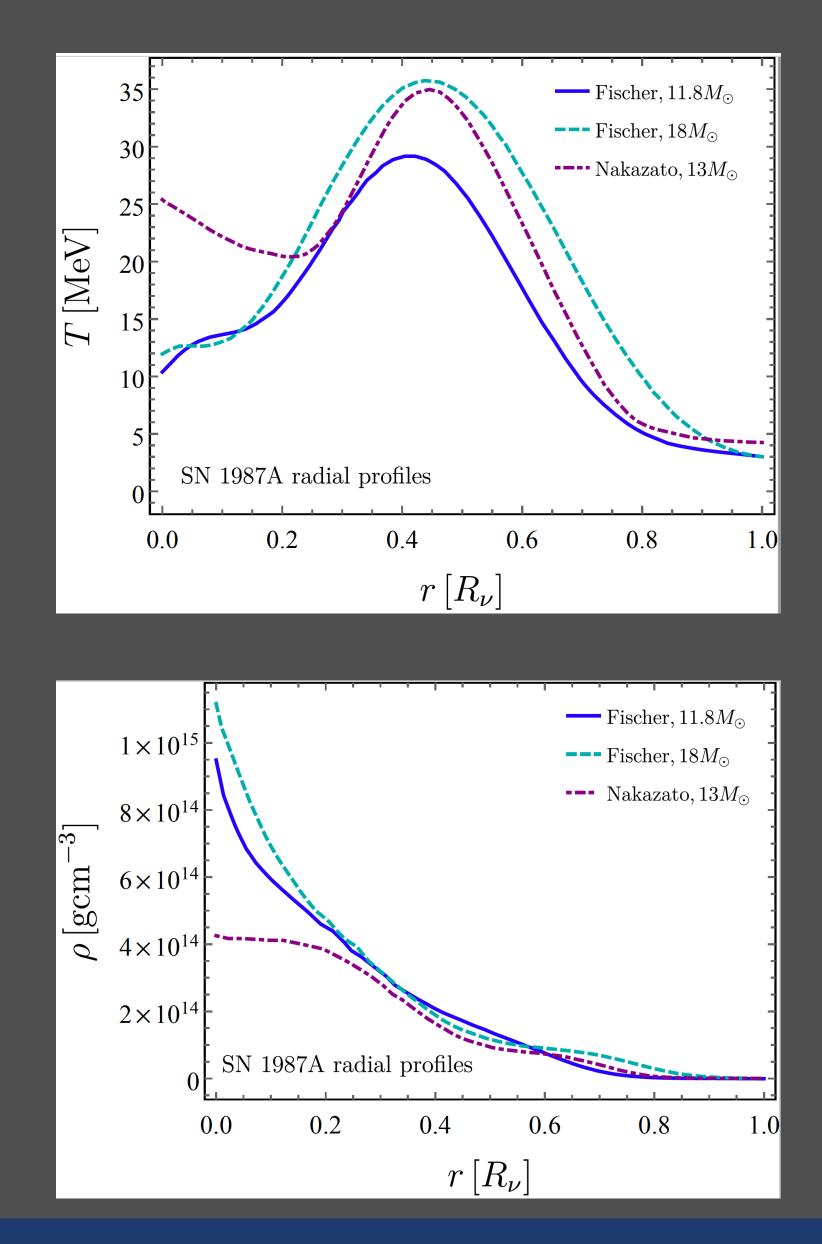

Shyam Balaji

• We adopt the numerical profiles \Rightarrow Fischer $11.8 M_{\odot}$

Neutrinosphere R_{ν}

- The production and absorption of S in the supernova core depend both on the baryon density $\rho(r)$ and temperature T(r)
- We make the following assumptions
 - 1. Neglect the production of S beyond the neutrinosphere R_{ν}
 - 2. Assuming the scalar S can stream freely outside the neutrinosphere R_{ν} without being absorbed.
 - 3. Treat protons and neutrons (nucleons) as being essentially the same

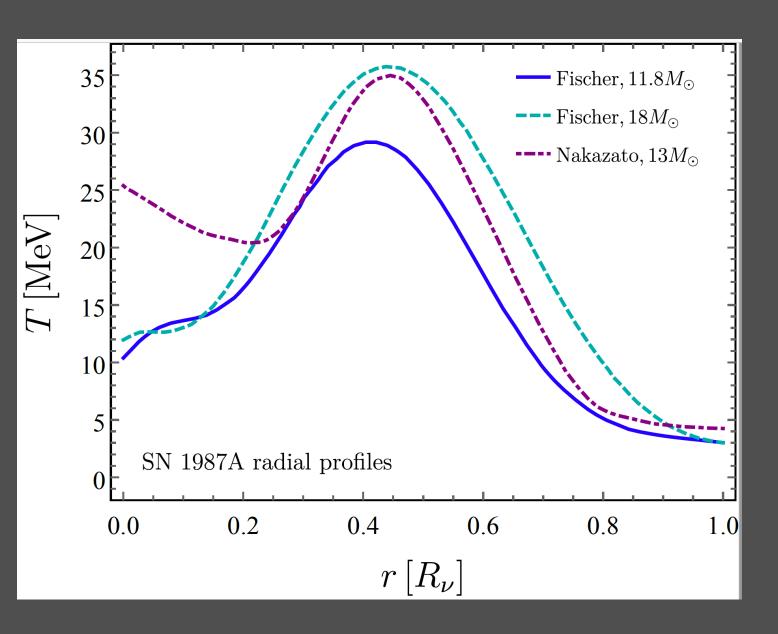

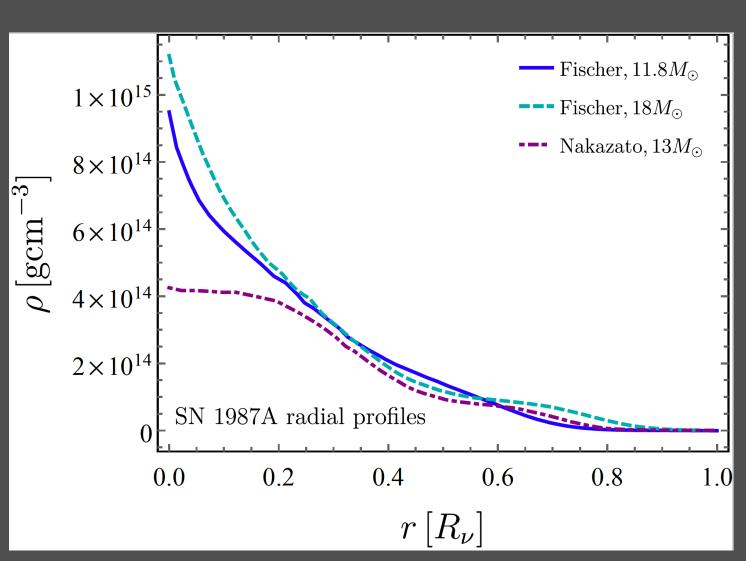

• 24.9 km (Fischer $11.8 M_{\odot}$)

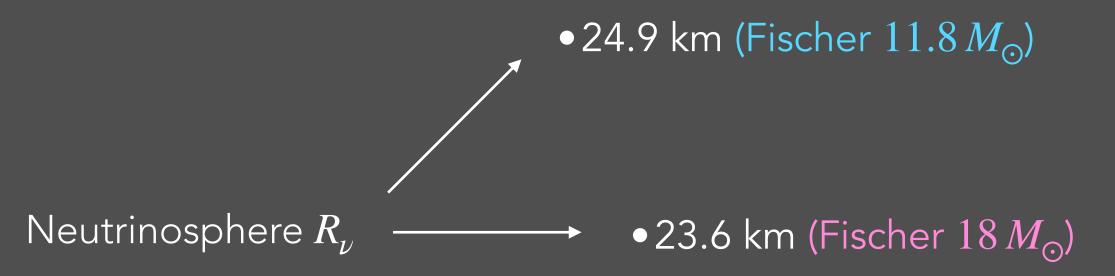

Neutrinosphere R_{ν}

- The production and absorption of S in the supernova core depend both on the baryon density $\rho(r)$ and temperature T(r)
- We make the following assumptions

$\mathcal{L} = \sin\theta S \left[y_{hNN} \overline{N} N + A_{\pi} (\pi^0 \pi^0 + \pi^+ \pi^-) \right]$

effective coupling of SM Higgs to nucleons $\simeq 10^{-3}$

effective coupling of S to pions from chiral perturbation theory

Shyam Balaji

Stellar limits on light CP-even scalar

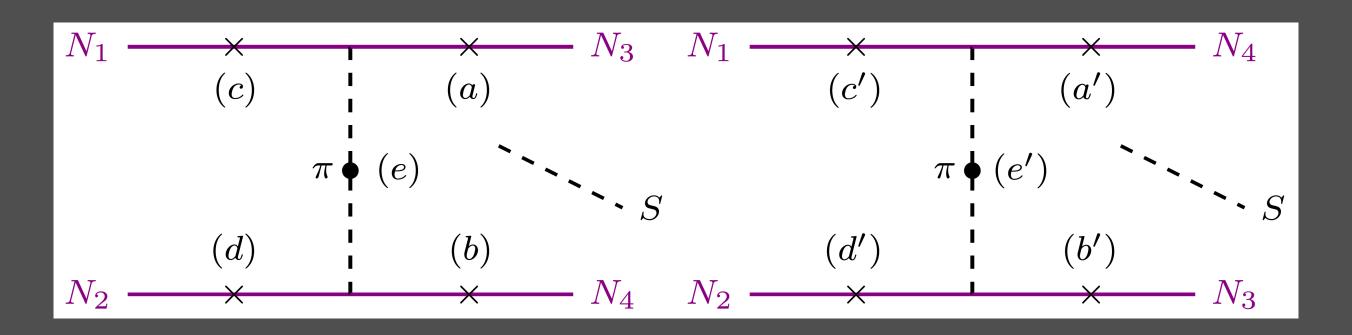

In the supernova core, the production of scalar S is dominated by the nucleon bremsstrahlung process

$$\left(m_S^2 + \frac{11}{2}m_\pi^2\right)$$

 $N + N \rightarrow N + N + S$

$\mathcal{L} = \sin\theta S \left[y_{hNN} \overline{N} N + A_{\pi} (\pi^0 \pi^0) \right]$

effective coupling of SM Higgs to nucleons $\simeq 10^{-3}$

effective coupling of S to pions from chiral perturbation theory

Shyam Balaji

$$+\pi^+\pi^-)]$$

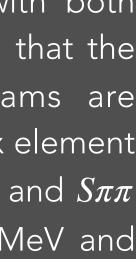

In the supernova core, the production of scalar S is dominated by the nucleon bremsstrahlung process

$$\left(m_S^2 + \frac{11}{2}m_\pi^2\right)$$

$N + N \rightarrow N + N + S$

Taking into account the couplings of S with both nucleons and the pion mediator, it is found that the contributions from the S-nucleon diagrams are partially canceled out. As a result, the matrix element for the process is dominated by the SNN and $S\pi\pi$ diagrams for the mass ranges of $m_S \gtrsim 10~{
m MeV}$ and $m_S \lesssim 10$ MeV, respectively.

GEOMETRIC DEPENDENCE

The probability of S to decay and the probability of S to be absorbed before escaping the star depends on the geometry: where it is produced and which direction it takes through the stellar medium

Spherical symmetry:

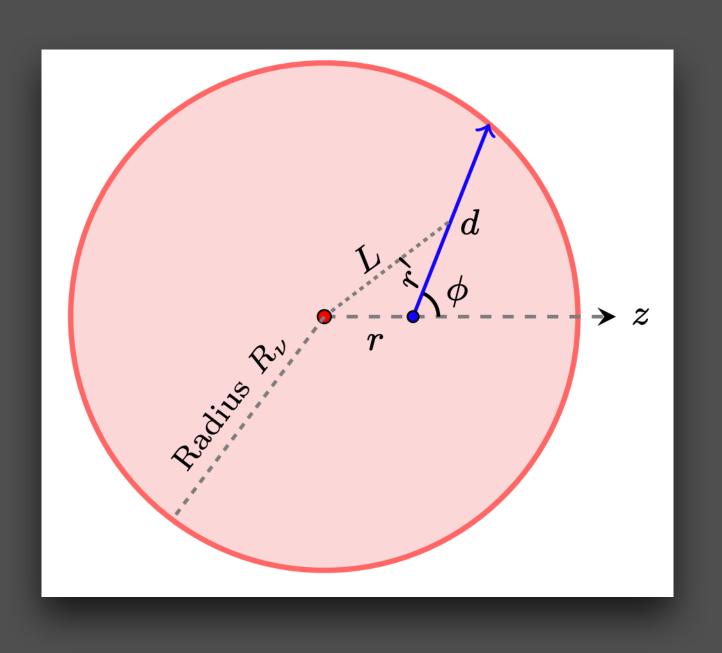

- The production site of S is determined by the distance r from the core
- Direction of the momentum of S is characterised by the polar angle ϕ

$$d(r,\phi) = \sqrt{R_{\star}^2 - r^2 \sin^2 \phi} - r \cos \phi \qquad \qquad L(r,\phi;r') = \sqrt{r^2 + r'^2 + 2rr' \cos \phi}$$

L varies when the auxiliary parameter r' changes from 0 to d.

Shyam Balaji

Stellar limits on light CP-even scalar

We integrate over r' in between 0 to d.

In the case of constant MFP λ , the absorption factor simply reduces to $\exp\{-d/\lambda\}$.

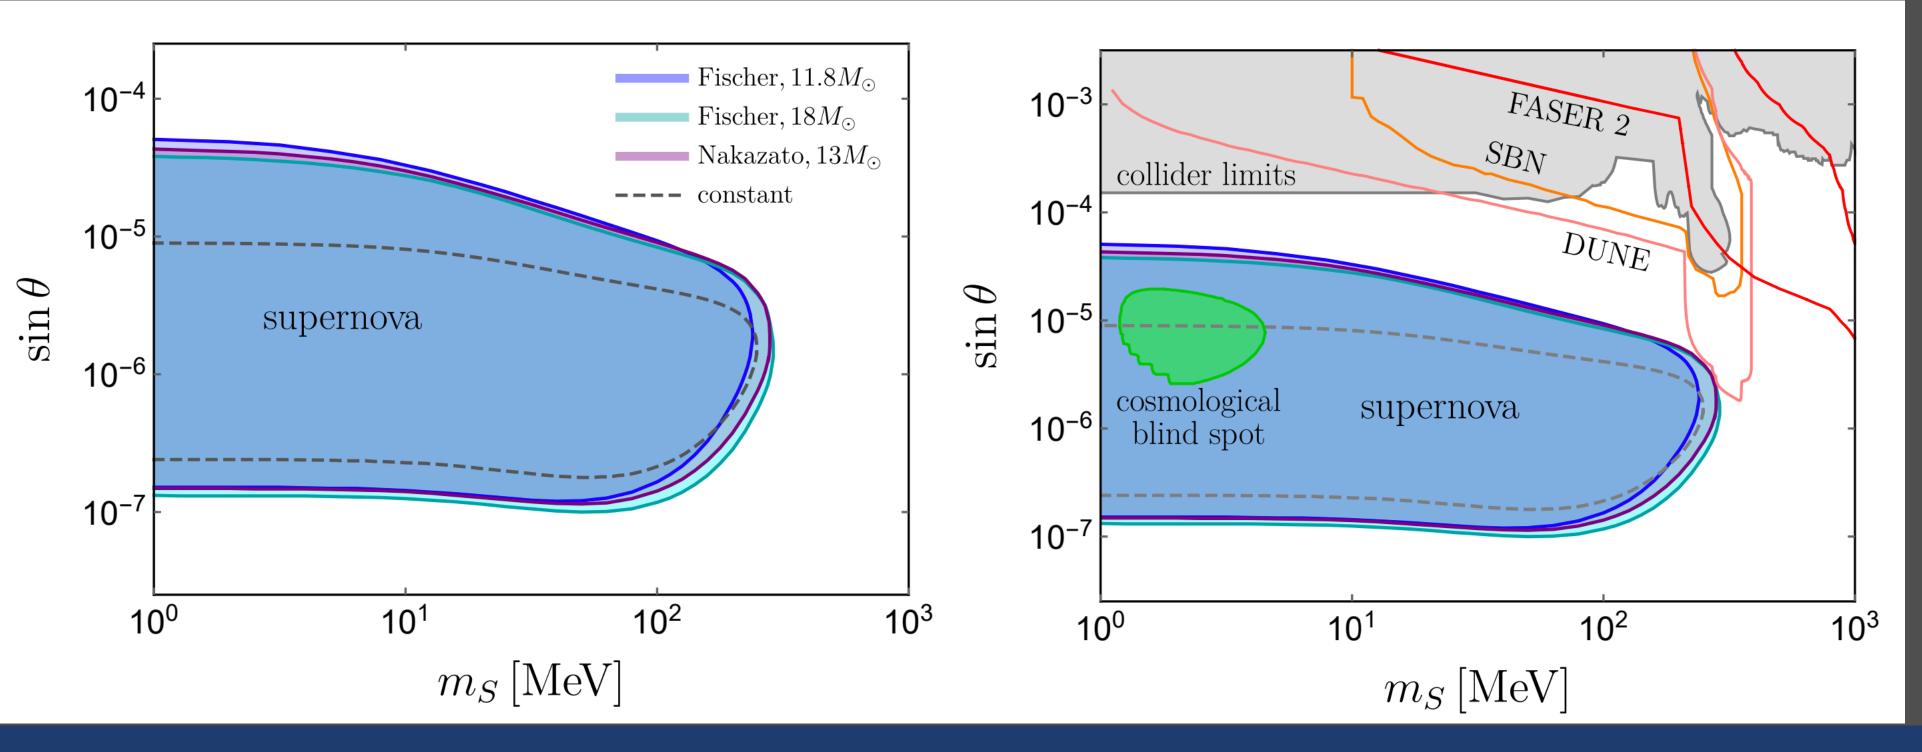

SN1987A LIMITS

• Integrating over the whole volume of SN1987A inside R_{ν} , we arrive at the luminosity due to the emission of the scalar S via the expression

$$\mathcal{L}_S = \int \mathcal{Q}(r,\phi) \mathrm{d}V = 2\pi \int_0^{R_\nu} \mathrm{d}r \, r^2 \int_0^{\pi} \mathrm{d}\phi \sin \phi \, \mathcal{Q}(r,\phi) \,.$$

• To set limits on the scalar mass m_S and the mixing angle sin θ , we conservatively require that the luminosity \mathscr{L}_S is smaller than 10% of the measured neutrino luminosity $\mathscr{L}_{\nu} = \simeq 3 \times 10^{53}$ erg/sec i.e. $\mathscr{L}_{S} < 3 \times 10^{52}$ erg/sec

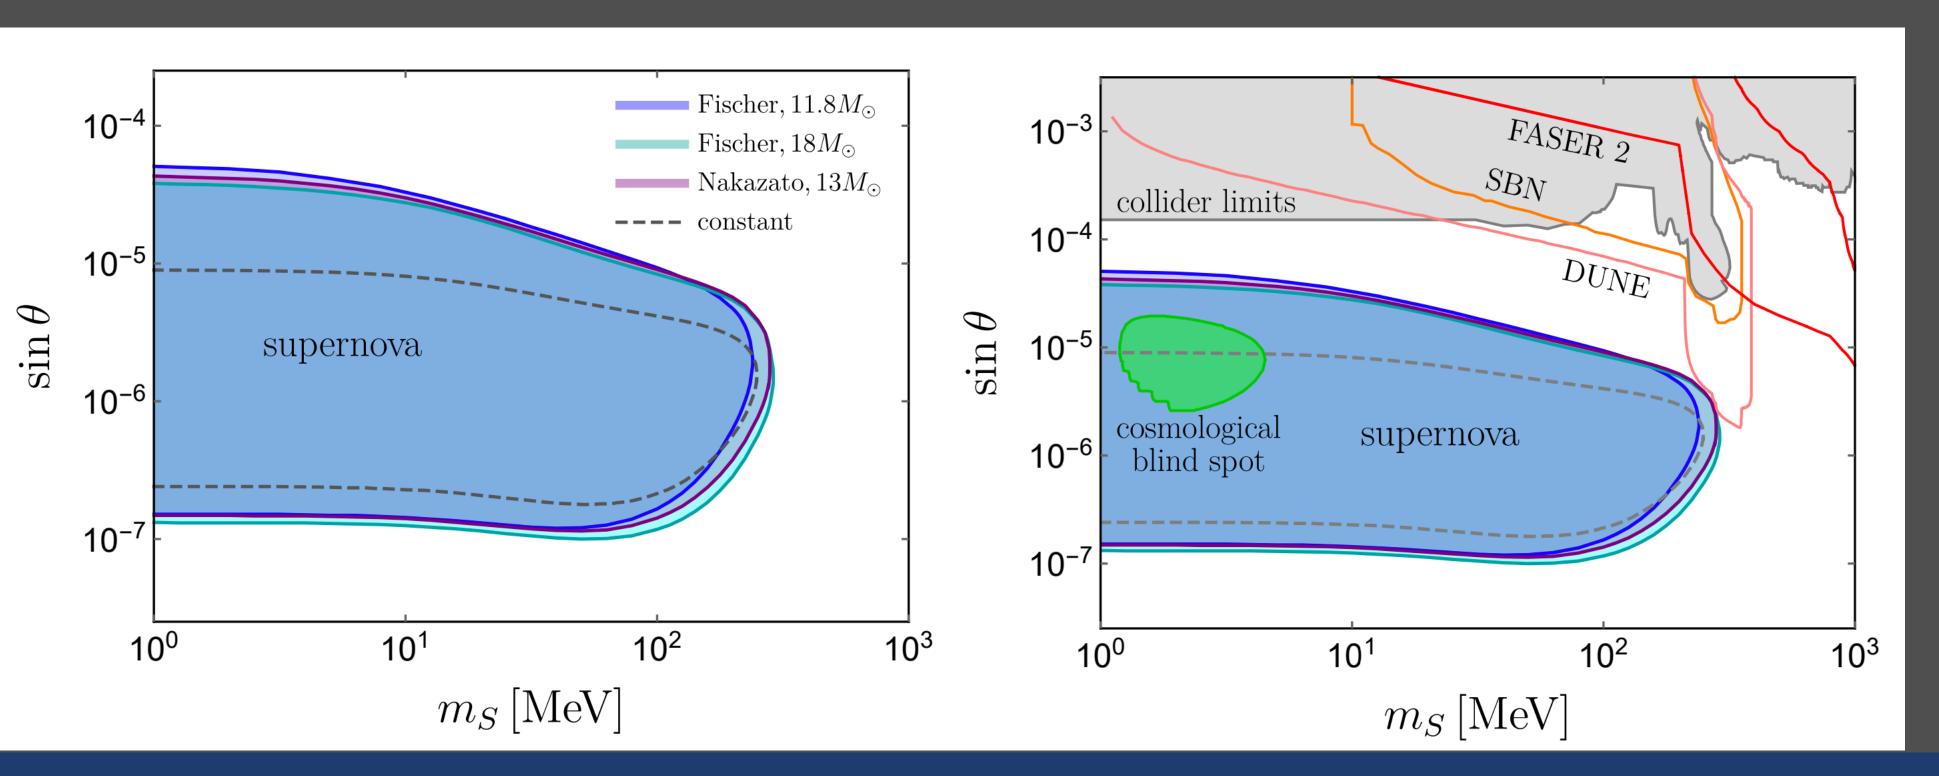

Shyam Balaji

The dashed (constant case) is shown for constant temperature $T = 30 \,\text{MeV}$ and baryon number $n_B = 1.2 \times 10^{38} \,\mathrm{cm}^{-3}.$

Shyam Balaji

• There is a "blind spot" left unconstrained (green region) that is consistent with CMB constraints on N_{eff}, µ and y distortions as well as post-

The cosmological "blind spot" is well excluded by the supernova limits with the three profiles adopted here. It is only partially excluded for the constant profile estimate.

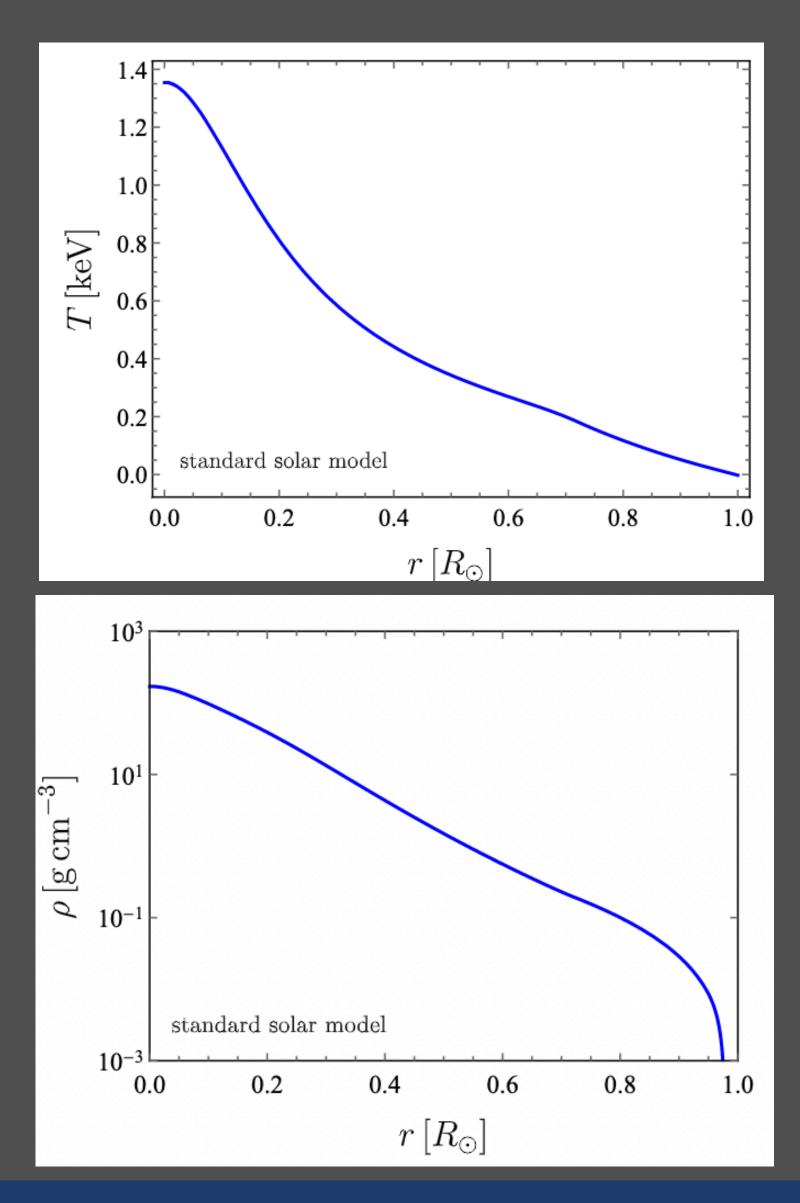

SOLAR RADIAL PROFILES

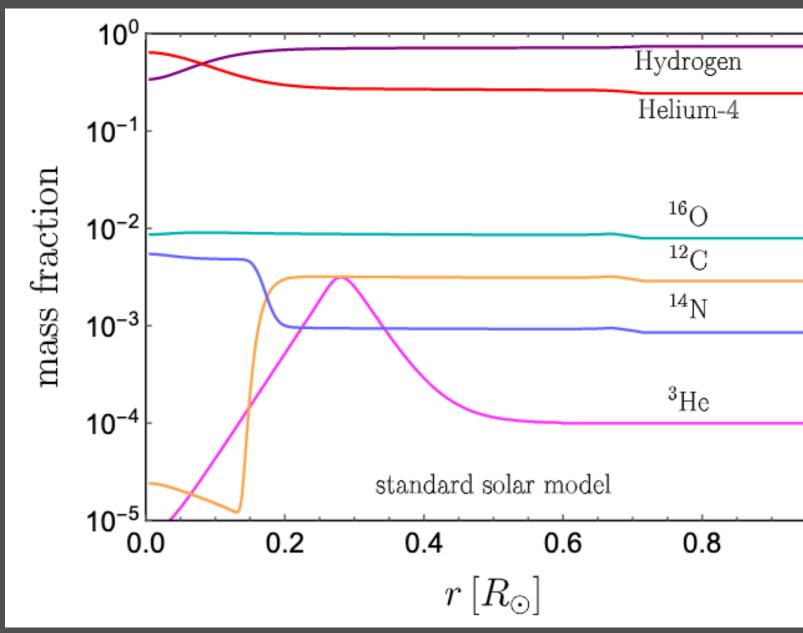

1.0

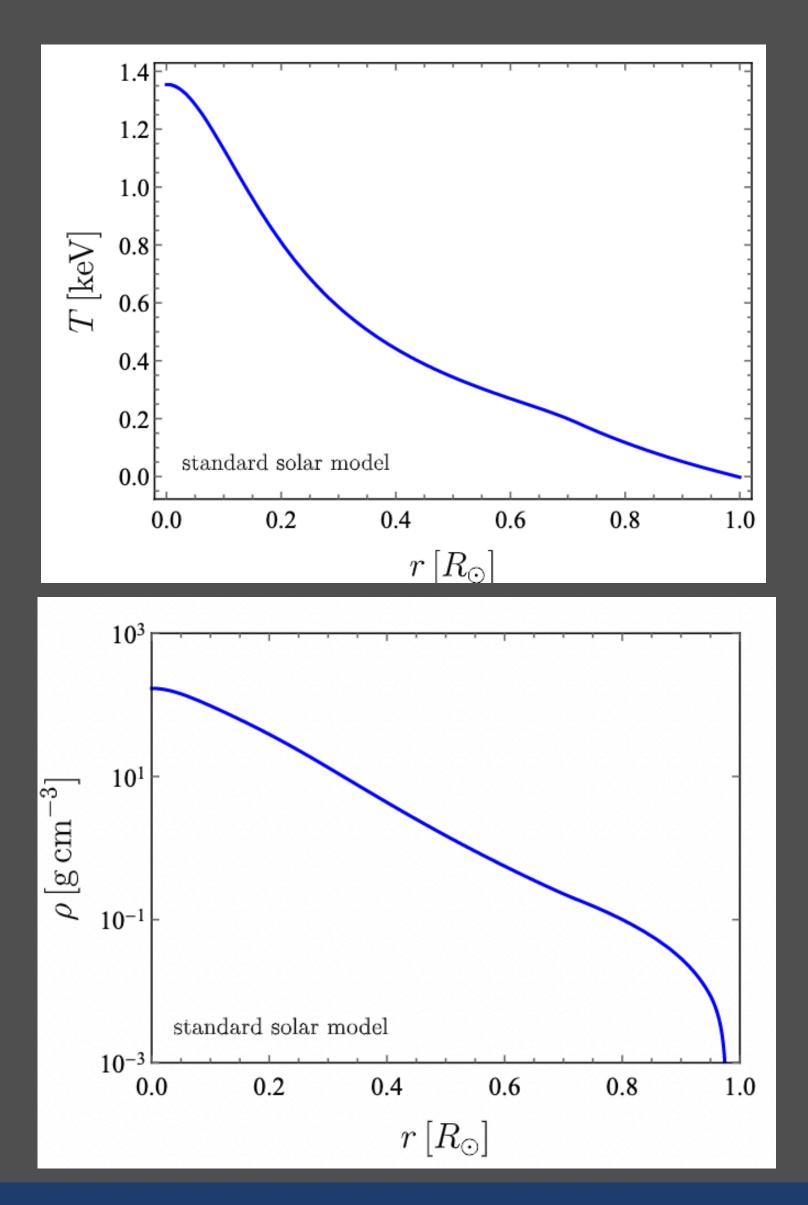

SOLAR RADIAL PROFILES

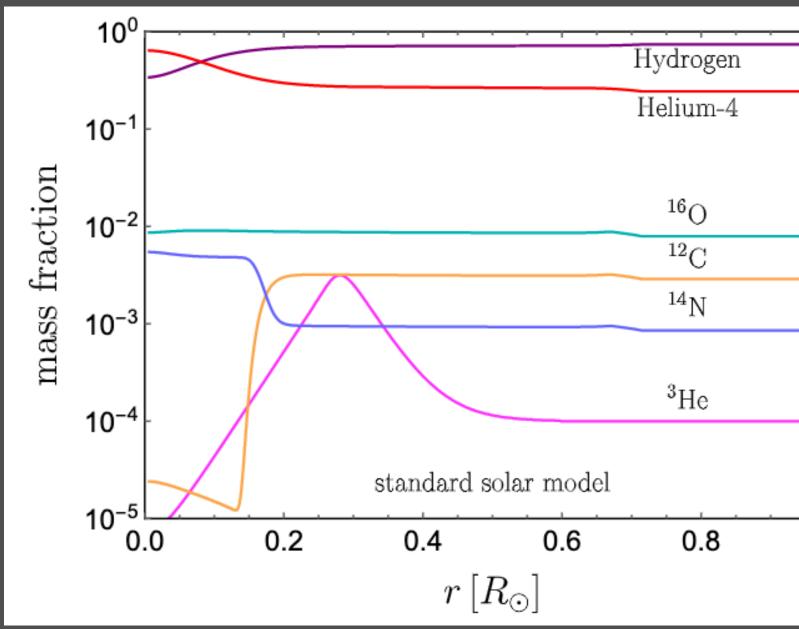

•The Sun is composed of mostly Hydrogen and Helium-4 ions, and their mass fractions are 34% and 64% at the solar core, changing smoothly to 74% and 24% at the solar surface. The remaining 2% mass fraction is Helium-3 and other heavy elements such as Carbon-12, Nitrogen-14 and Oxygen-16.

Limits on light CP-even scalar S from SN1987A, the Sun, RGs and WDs obtained in this paper including the geometric factor and stellar profiles to those with constant temperature, density and mass fractions. The second and third columns indicate the stellar profile adopted and whether geometry is included, respectively. The fourth and fifth columns are the excluded ranges of $\sin \theta$ and m_s , respectively.

VARIABLE DEFINITIONS

Where we utilised the following dimensionless variables

$$u \equiv \frac{\mathbf{p}_i^2}{m_N T}, \qquad v \equiv \frac{\mathbf{p}_f^2}{m_N T}, \qquad x \equiv \frac{E_S}{T}, \qquad q \equiv \frac{m_S}{T}, \qquad y \equiv \frac{m_{\pi}^2}{m_N T}$$

nucleons in the final state, we define

$\mathbf{p}_1 \equiv \mathbf{P} + \mathbf{p}_i, \quad \mathbf{p}_2 \equiv \mathbf{P} - \mathbf{p}_i, \quad \mathbf{p}_3 \equiv \mathbf{P} + \mathbf{p}_f, \quad \mathbf{p}_4 \equiv \mathbf{P} - \mathbf{p}_f,$

The dimensionless function \mathscr{F}_{tot} is given given in the Appendix in terms of dimensionless variables u, x, y and z

Shyam Balaji

Stellar limits on light CP-even scalar

Denoting \mathbf{p}_i (with i = 1, 2, 3, 4) as the three-momenta for the two nucleons in the initial state of the nucleon bremsstrahlung process and the two

After many simplifications, we arrive at the following expressions for the emission rate

$$\mathcal{Q}(r,\,\phi) = \frac{\alpha_{\pi}^2 f_{pp}^4 \sin^2 \theta T^{7/2}(r) \rho^2(r)}{8\pi^{3/2} m_N^{13/2}} \int_q^\infty \mathrm{d}u \int_0^\infty \mathrm{d}v \int_{-1}^1 \mathrm{d}z \int_q^\infty \mathrm{d}x \,\,\delta(u-v-x) \sqrt{uv} e^{-u} x \sqrt{x^2 - q^2} P_{\text{decay}} P_{\text{abs}} \mathcal{I}_{\text{tot}}$$

$$\mathcal{Q}(r,\phi) = \frac{\alpha_{\pi}^{2} f_{pp}^{4} \sin^{2} \theta T^{7/2}(r) \rho^{2}(r)}{8\pi^{3/2} m_{N}^{13/2}} \int_{q}^{\infty} \mathrm{d}u \int_{0}^{\infty} \mathrm{d}v \int_{-1}^{1} \mathrm{d}z \int_{q}^{\infty} \mathrm{d}x \,\,\delta(u-v-x) \sqrt{uv} e^{-u} x \sqrt{x^{2}-q^{2}} P_{\mathrm{decay}} P_{\mathrm{abs}} \mathcal{I}_{\mathrm{tot}}$$

$$\alpha_{\pi} \equiv (2m_N/m_{\pi})^2/4\pi \simeq 15$$

After many simplifications, we arrive at the following expressions for the emission rate

$$\mathcal{Q}(r,\phi) = \frac{\alpha_{\pi}^{2} f_{pp}^{4} \sin^{2} \theta T^{7/2}(r) \rho^{2}(r)}{8\pi^{3/2} m_{N}^{13/2}} \int_{q}^{\infty} \mathrm{d}u \int_{0}^{\infty} \mathrm{d}v \int_{-1}^{1} \mathrm{d}z \int_{q}^{\infty} \mathrm{d}x \,\,\delta(u-v-x) \sqrt{uv} e^{-u} x \sqrt{x^{2}-q^{2}} P_{\mathrm{decay}} P_{\mathrm{abs}} \mathcal{I}_{\mathrm{tot}}$$

$$\alpha_{\pi} \equiv (2m_N/m_{\pi})^2/4\pi \simeq 15$$

where $f_{pp} = 1$. The above contains within P_{abs} the inverse mean free path

After many simplifications, we arrive at the following expressions for the emission rate

$$\mathcal{Q}(r, \phi) = \frac{\alpha_{\pi}^2 f_{pp}^4 \sin^2 \theta T^{7/2}(r) \rho^2(r)}{\sqrt{8\pi^{3/2} m_N^{13/2}}} \int_q^\infty \mathrm{d}u \int_0^\infty \mathrm{d}v \int_{-1}^1 \mathrm{d}z \int_q^\infty \mathrm{d}x \,\,\delta(u - v - x) \sqrt{uv} e^{-u} x \sqrt{x^2 - q^2} P_{\text{decay}} P_{\text{abs}} \mathcal{I}_{\text{tot}}$$

$$\alpha_{\pi} \equiv (2m_N/m_{\pi})^2/4\pi \simeq 15$$

where $f_{pp} = 1$. The above contains within P_{abs} the inverse mean free path

$$\lambda^{-1}(r;x) = \frac{\pi^{1/2} \alpha_{\pi}^2 f_{pp}^4 \sin^2 \theta \rho^2(r)}{4m_N^{13/2} T^{1/2}(r)} \frac{1}{x} \int_0^\infty \mathrm{d}u \int_q^\infty \mathrm{d}v \int_{-1}^1 \mathrm{d}z \sqrt{uv} e^{-u} \delta(u-v+x) \mathcal{I}_{\mathrm{tot}}(u-v+x) \mathcal{I}_{$$

After many simplifications, we arrive at the following expressions for the emission rate

$$\mathcal{Q}(r, \phi) = \frac{\alpha_{\pi}^2 f_{pp}^4 \sin^2 \theta T^{7/2}(r) \rho^2(r)}{\sqrt{8\pi^{3/2} m_N^{13/2}}} \int_q^\infty \mathrm{d}u \int_0^\infty \mathrm{d}v \int_{-1}^1 \mathrm{d}z \int_q^\infty \mathrm{d}x \,\,\delta(u - v - x) \sqrt{uv} e^{-u} x \sqrt{x^2 - q^2} P_{\text{decay}} P_{\text{abs}} \mathcal{I}_{\text{tot}}$$

$$\alpha_{\pi} \equiv (2m_N/m_{\pi})^2/4\pi \simeq 15$$

where $f_{pp} = 1$. The above contains within P_{abs} the inverse mean free path

$$\lambda^{-1}(r;x) = \frac{\pi^{1/2} \alpha_{\pi}^2 f_{pp}^4 \sin^2 \theta \rho^2(r)}{4m_N^{13/2} T^{1/2}(r)} \frac{1}{x} \int_0^\infty \mathrm{d}u \int_q^\infty \mathrm{d}v \int_{-1}^1 \mathrm{d}z \sqrt{uv} e^{-u} \delta(u-v+x) \mathcal{I}_{\mathrm{tot}}(u-v+x) \mathcal{I}_{$$

From here we may numerically solve for the luminosity due to light scalar emission

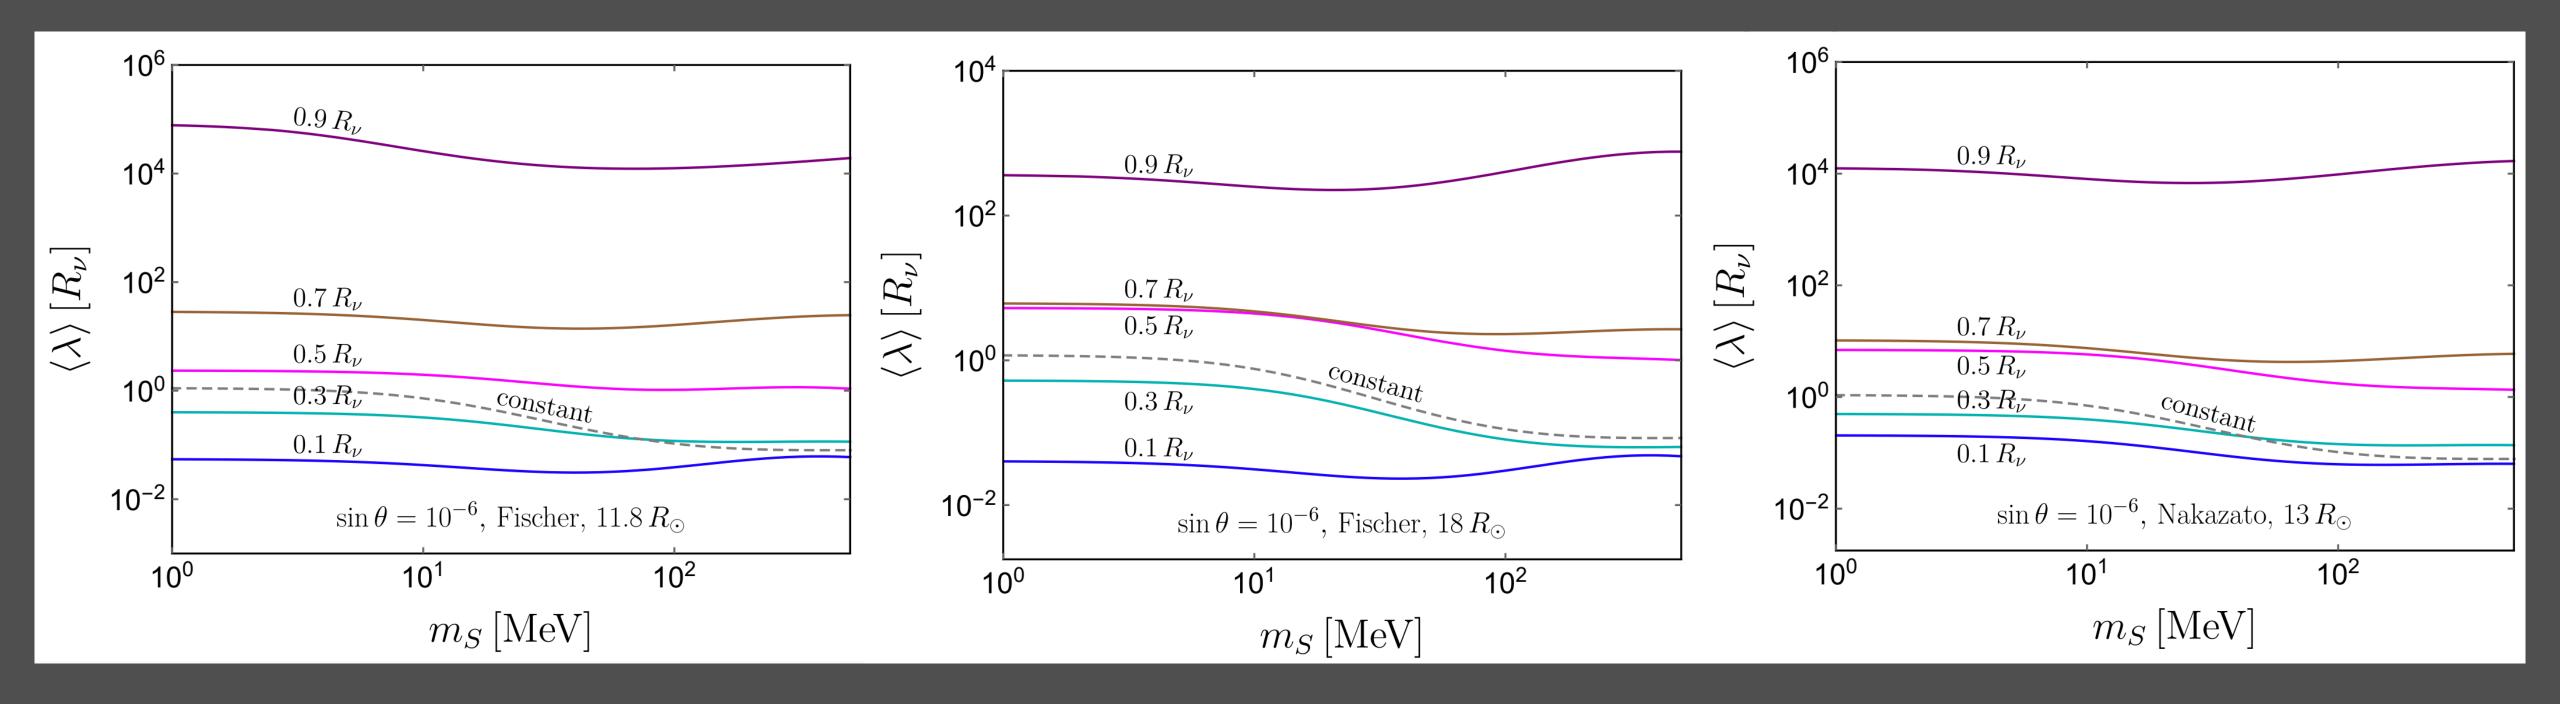

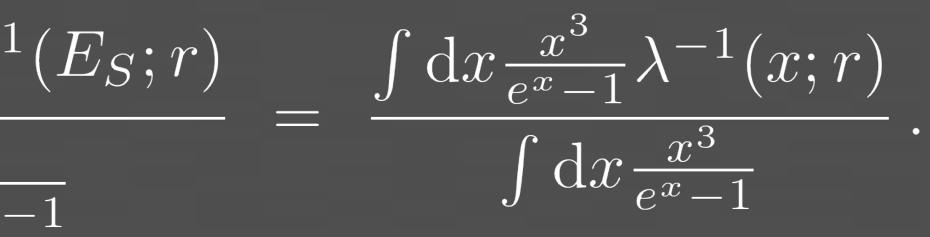

ENERGY AVERAGED MEAN FREE PATH

$$\langle \lambda^{-1} \rangle (r) \equiv \frac{\int \mathrm{d}E_S \frac{E_S^3}{e^{E_S/T} - 1} \lambda^{-1}}{\int \mathrm{d}E_S \frac{E_S^3}{e^{E_S/T}}}$$

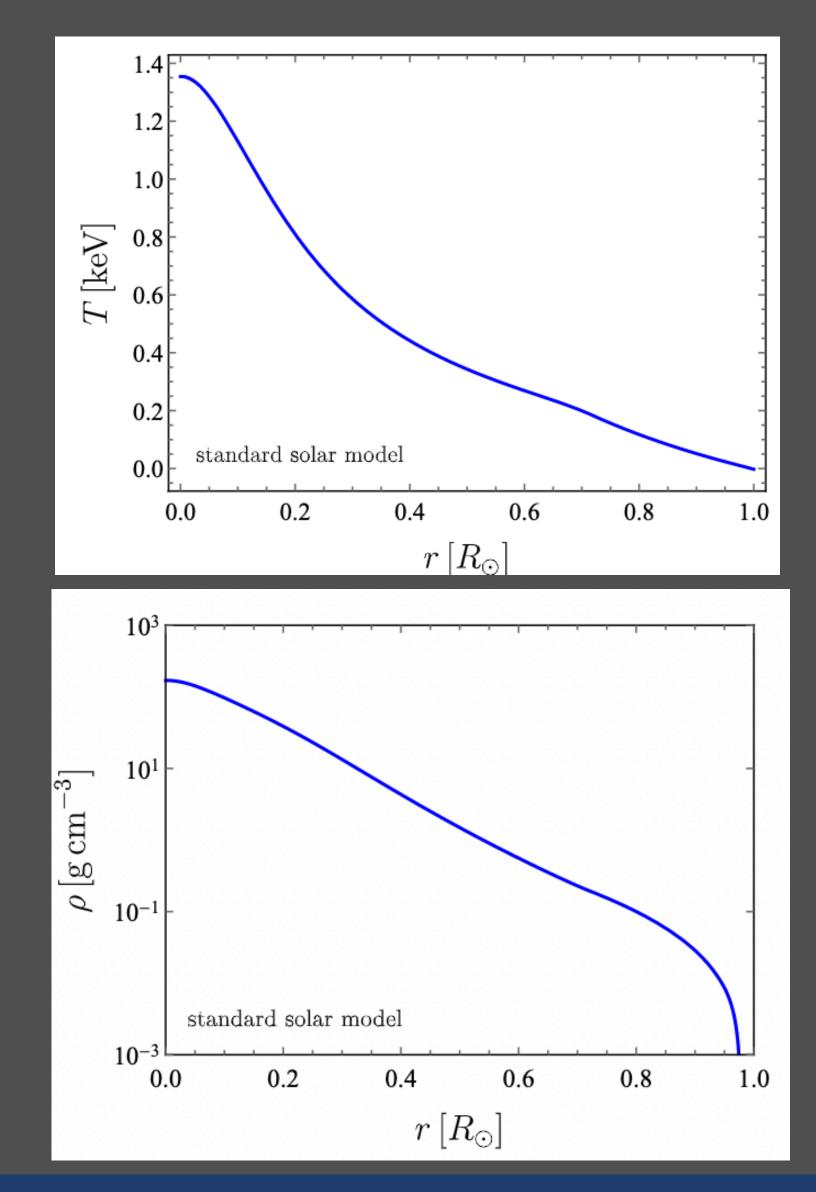

The dashed lines are the corresponding MFPs for constant temperature T = 30 MeV and baryon number density $n_B = 1.2 \times 10^{38}$ cm⁻³. The mixing angle is fixed to $\sin \theta = 10^{-6}$

From here we may once again numerically solve for the luminosity due to light scalar emission

ENERGY AVERAGED MEAN FREE PATH

$$\langle \lambda^{-1} \rangle(r) \equiv \frac{\int \mathrm{d}E_S \frac{E_S^3}{e^{E_S/T}}}{\int \mathrm{d}E_S \frac{1}{e^{E_S/T}}}$$

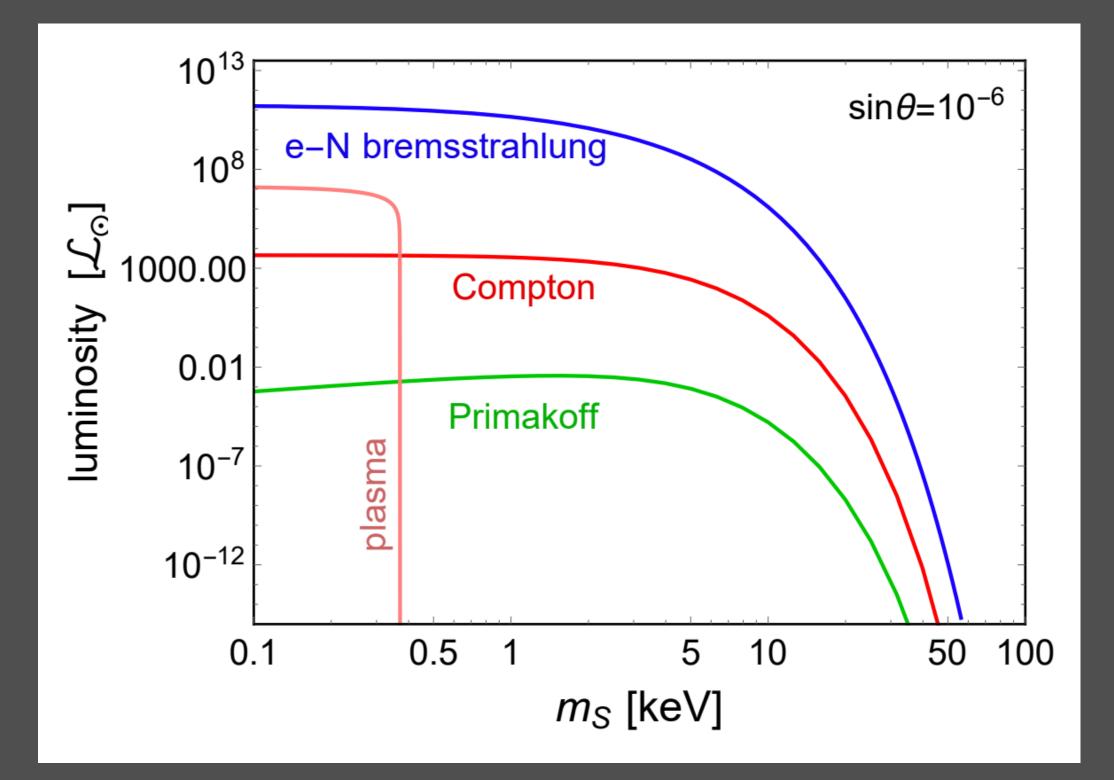

The dashed lines are the corresponding MFPs for constant temperature T = 1 keV and the electron number density $n_e = 10^{26}$ cm⁻³. The mixing angle is fixed to $\sin \theta = 10^{-6}$
