Dep. Theoretical Physics  
Universidad de Zaragoza

MAX-PLANCK-GESELLSCHAFT

MPP Munich

# axion DM experiments need to scan its mass ... they could use a hint

-From  $f_a \sim 10^{19}$  GeV to  $f_a \sim 10^8$  GeV 11 orders of magnitude in axion mass to scan ...  
 $10^{17}$  channels in mass ...

## Cavities

## Mirrors

## Oscillating EDM

## LC-circuit

## Ferromagnetic resonance

## Atomic transitions

# any theory bias?

## - String theory?

- weakly coupled heterotic string

$$f_A \simeq 1.1 \times 10^{16} \text{ GeV}$$

$$m_A \simeq 5.2 \times 10^{-10} \text{ eV}$$

Witten 1985

- ... plenty of other possibilities

See e.g. Svrček 2006

## - Grand Unified Theories

see e.g. Ernst 2018

## - Supersymmetry

- No strong theory bias, mostly pheno

## - Simple complete-models PP+Cosmo (SMASH-like)

Ballesteros 2017

- Motivations are pheno

# any bias from phenomenology?

## - Measurement available

### - Axion DM abundance

$$\Omega_A(m_A)h^2 \leq 0.12$$

$$m_A \geq 42 \text{ tbc}$$

*tbc, to be confirmed units*

## - Measurements possible in the future

-Observed galactic/extragalactic MW lines from axion DM decay ?

-Black hole spin depletion?

-Microlensing/femtolensing/other type of events from axion miniclusters?

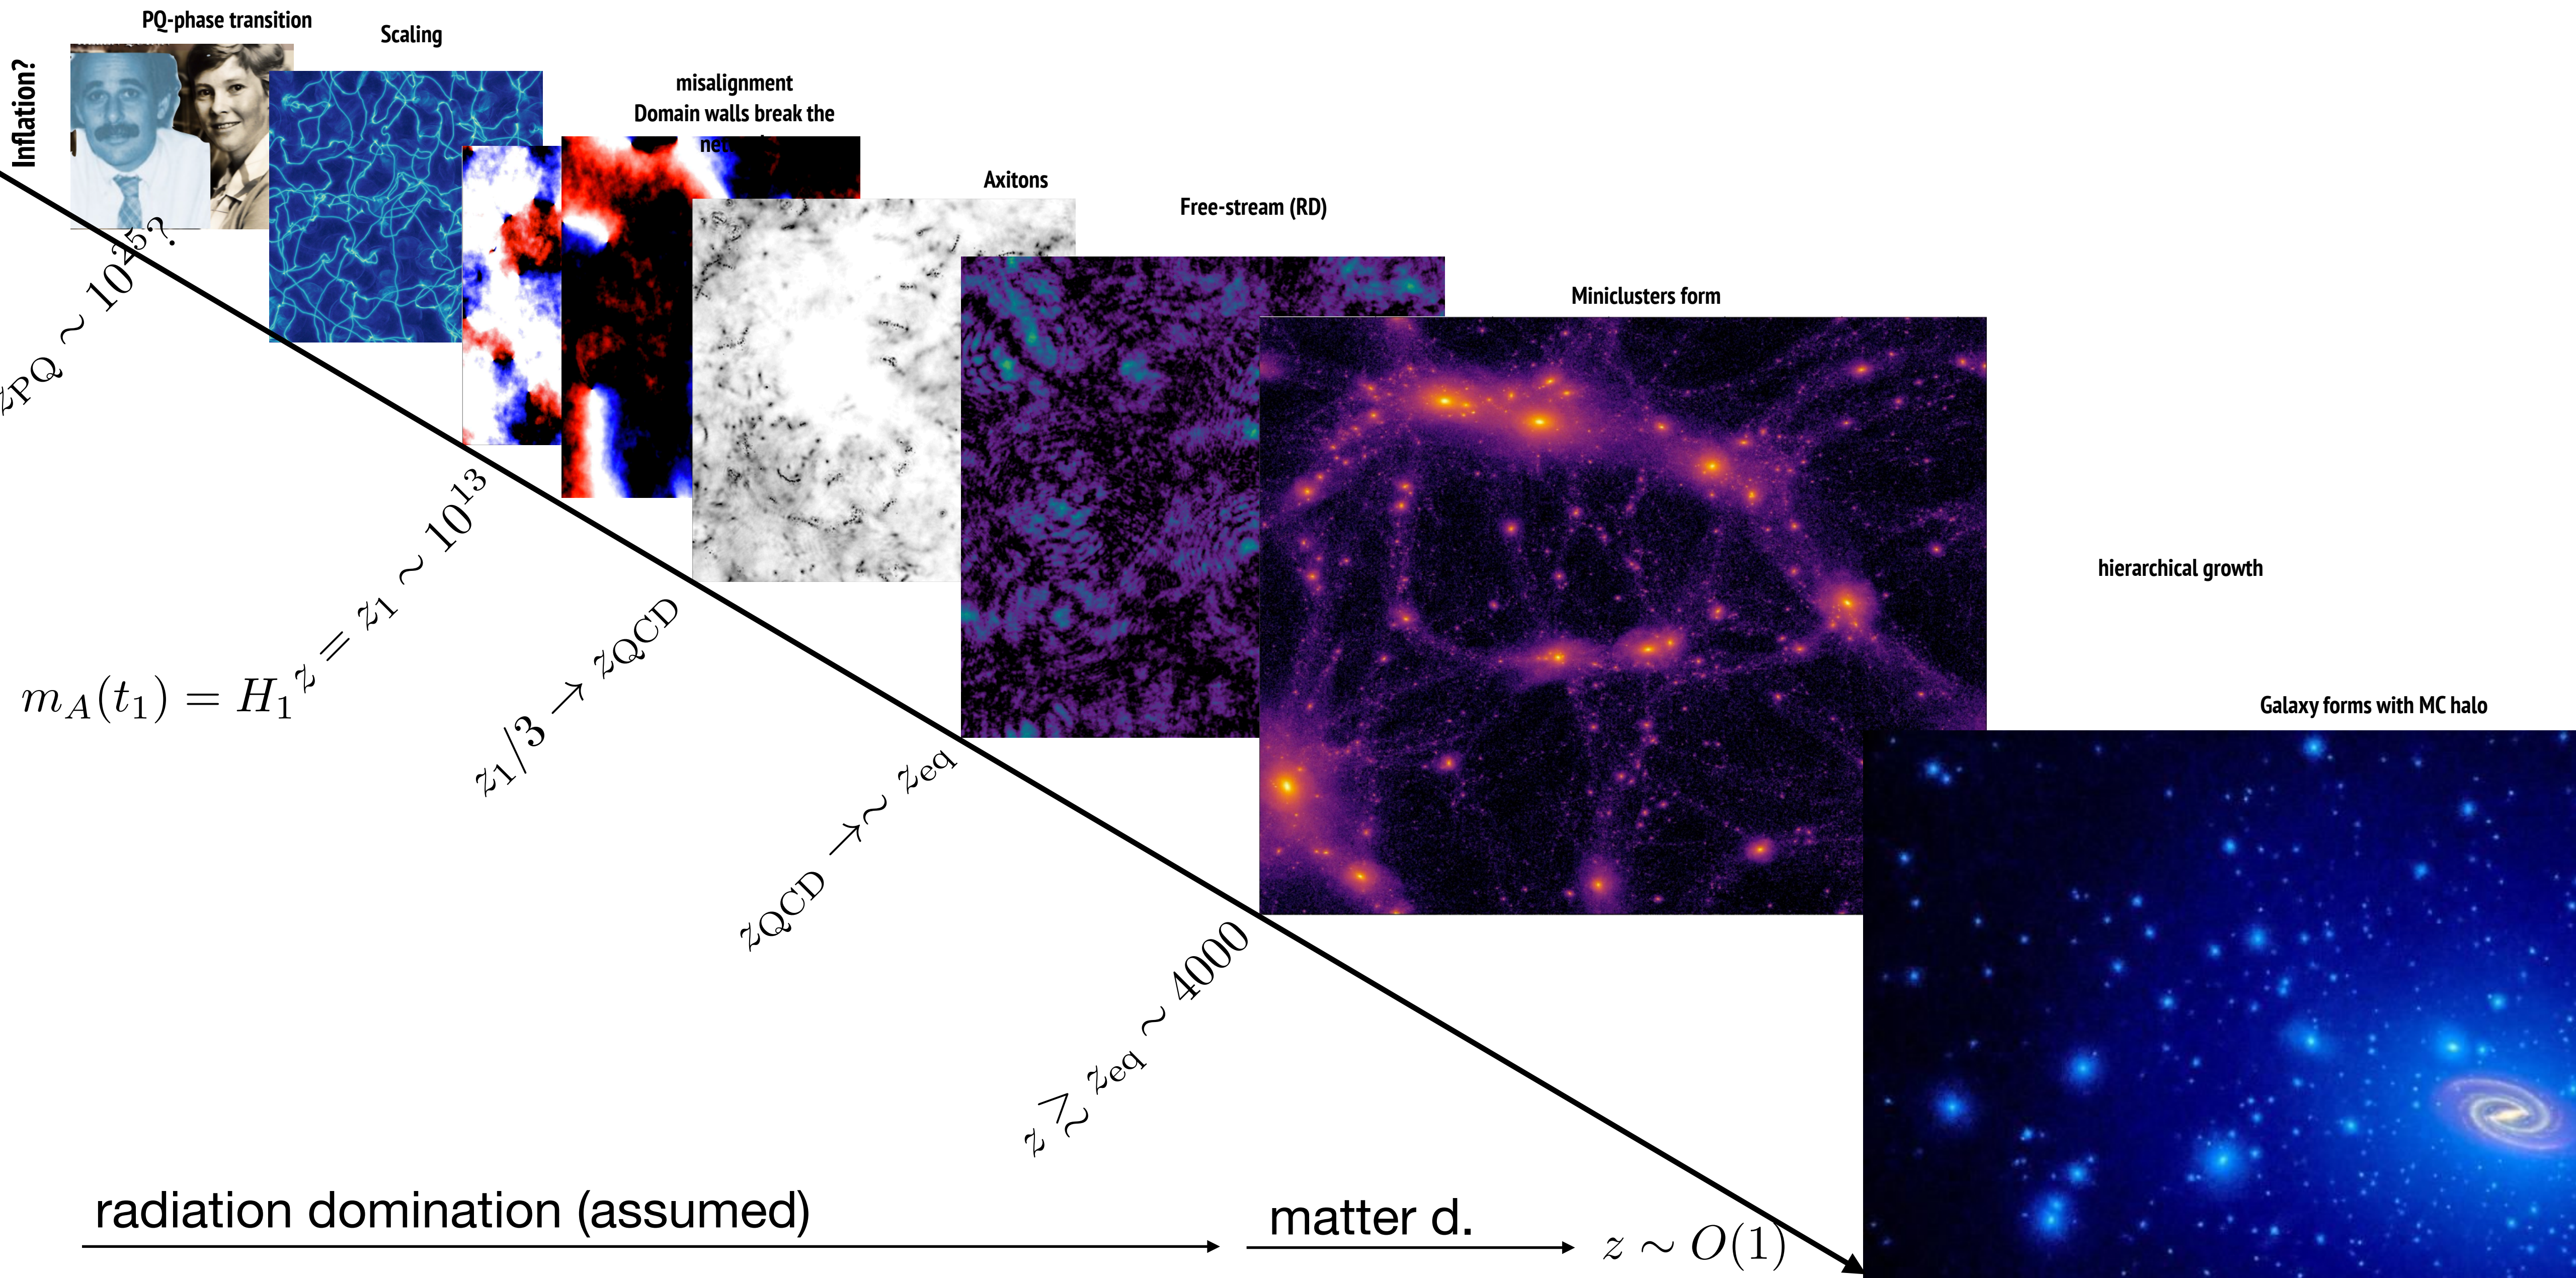

-birefringence/dichroism?

# Axion DM mass: ICs and Cosmology

# post-inflationary scenario N=1

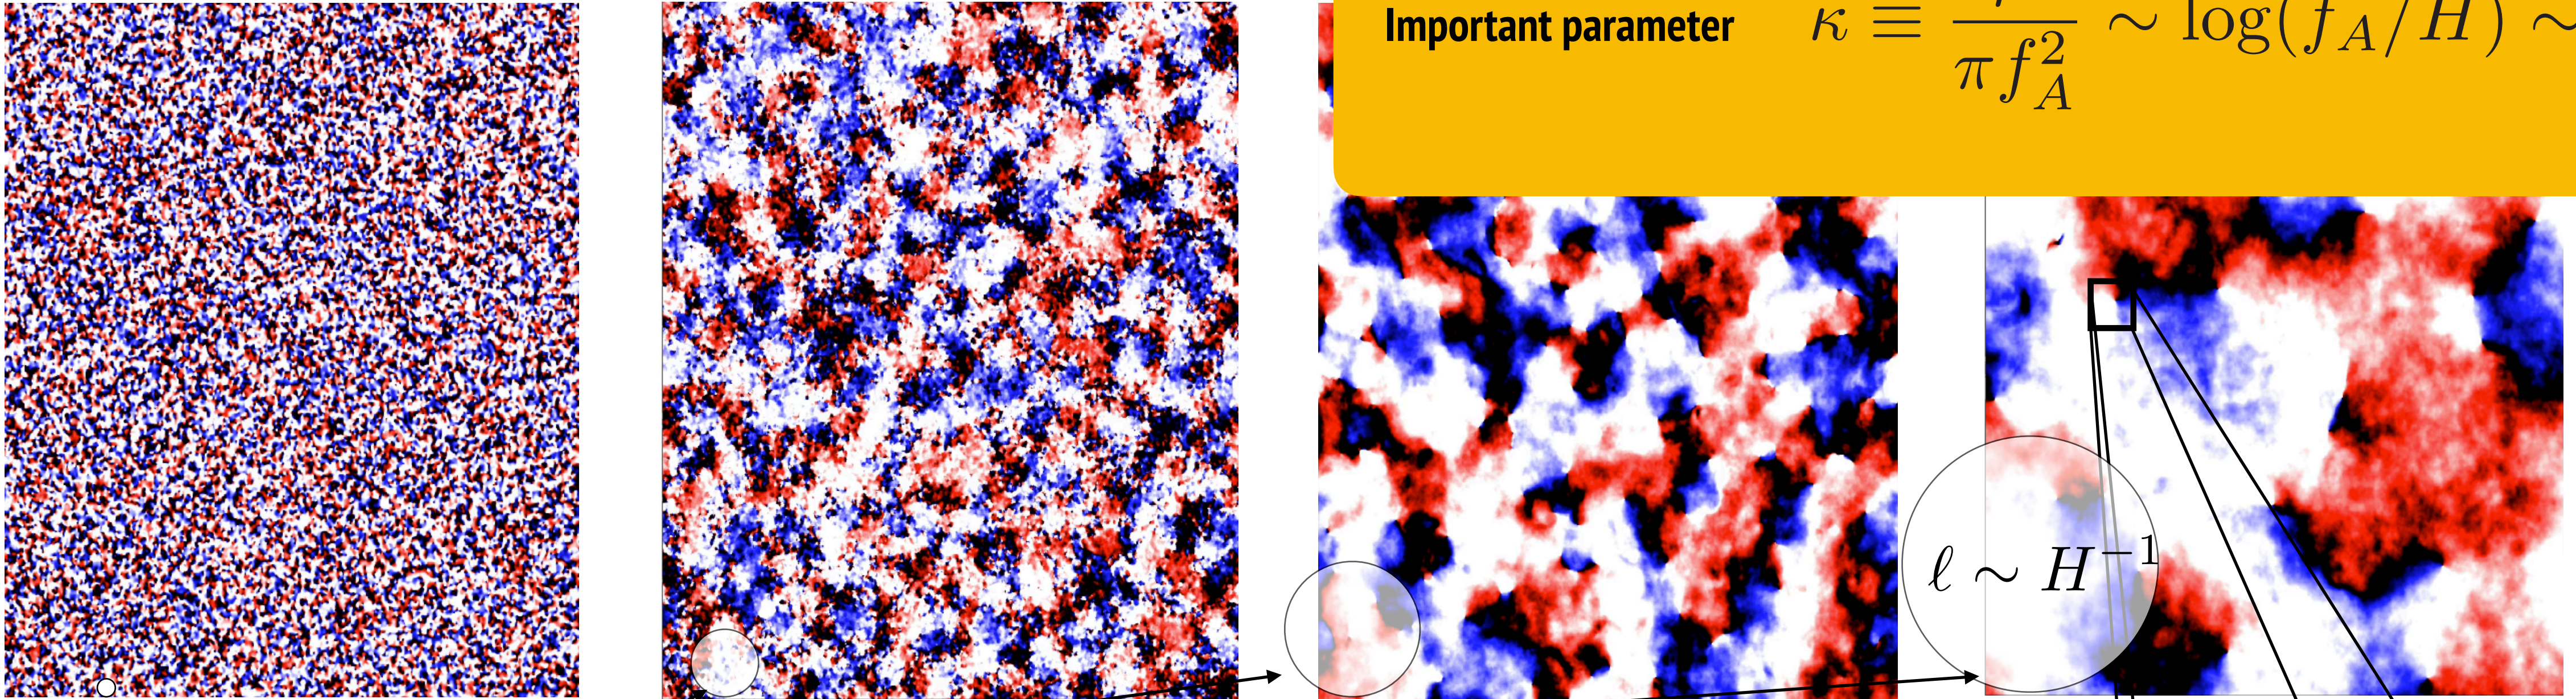

# Postinflation scenario, the problem

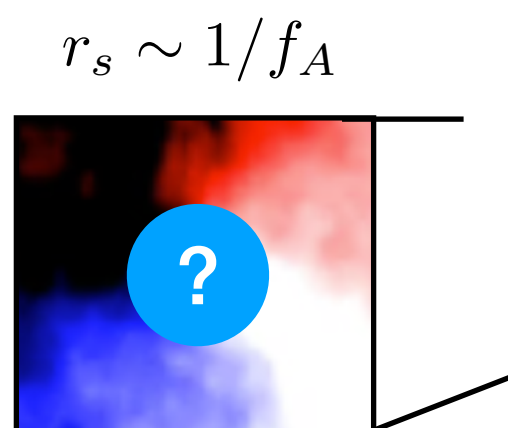

- Axion strings form by Kibble mechanism
- Energy logarithmically distributed around, tension  $\mu \simeq \pi f_A^2 \log\left(\frac{f_A}{H}\right)$

- SIMULATION REQUIRES DYNAMICAL RANGE  $\sim f_A/H \sim 10^{30}$  (available  $\sim 10^3$ )

Important parameter  $\kappa \equiv \frac{\mu}{\pi f_A^2} \sim \log(f_A/H) \sim 70$

1 - Horizon size  $\sim$  time, fields become uniform  $\sim$  horizon size (Fourier modes start decaying when  $t \sim 1/k$ )

... ..

# How to tackle the energy problem (get the right axion number)

Two approaches:

**Direct simulation : 1) Simulate and 2) count the axions, extrapolate**

*Moore, Redondo, Buschmann*

$\kappa \sim \log(\lambda)$

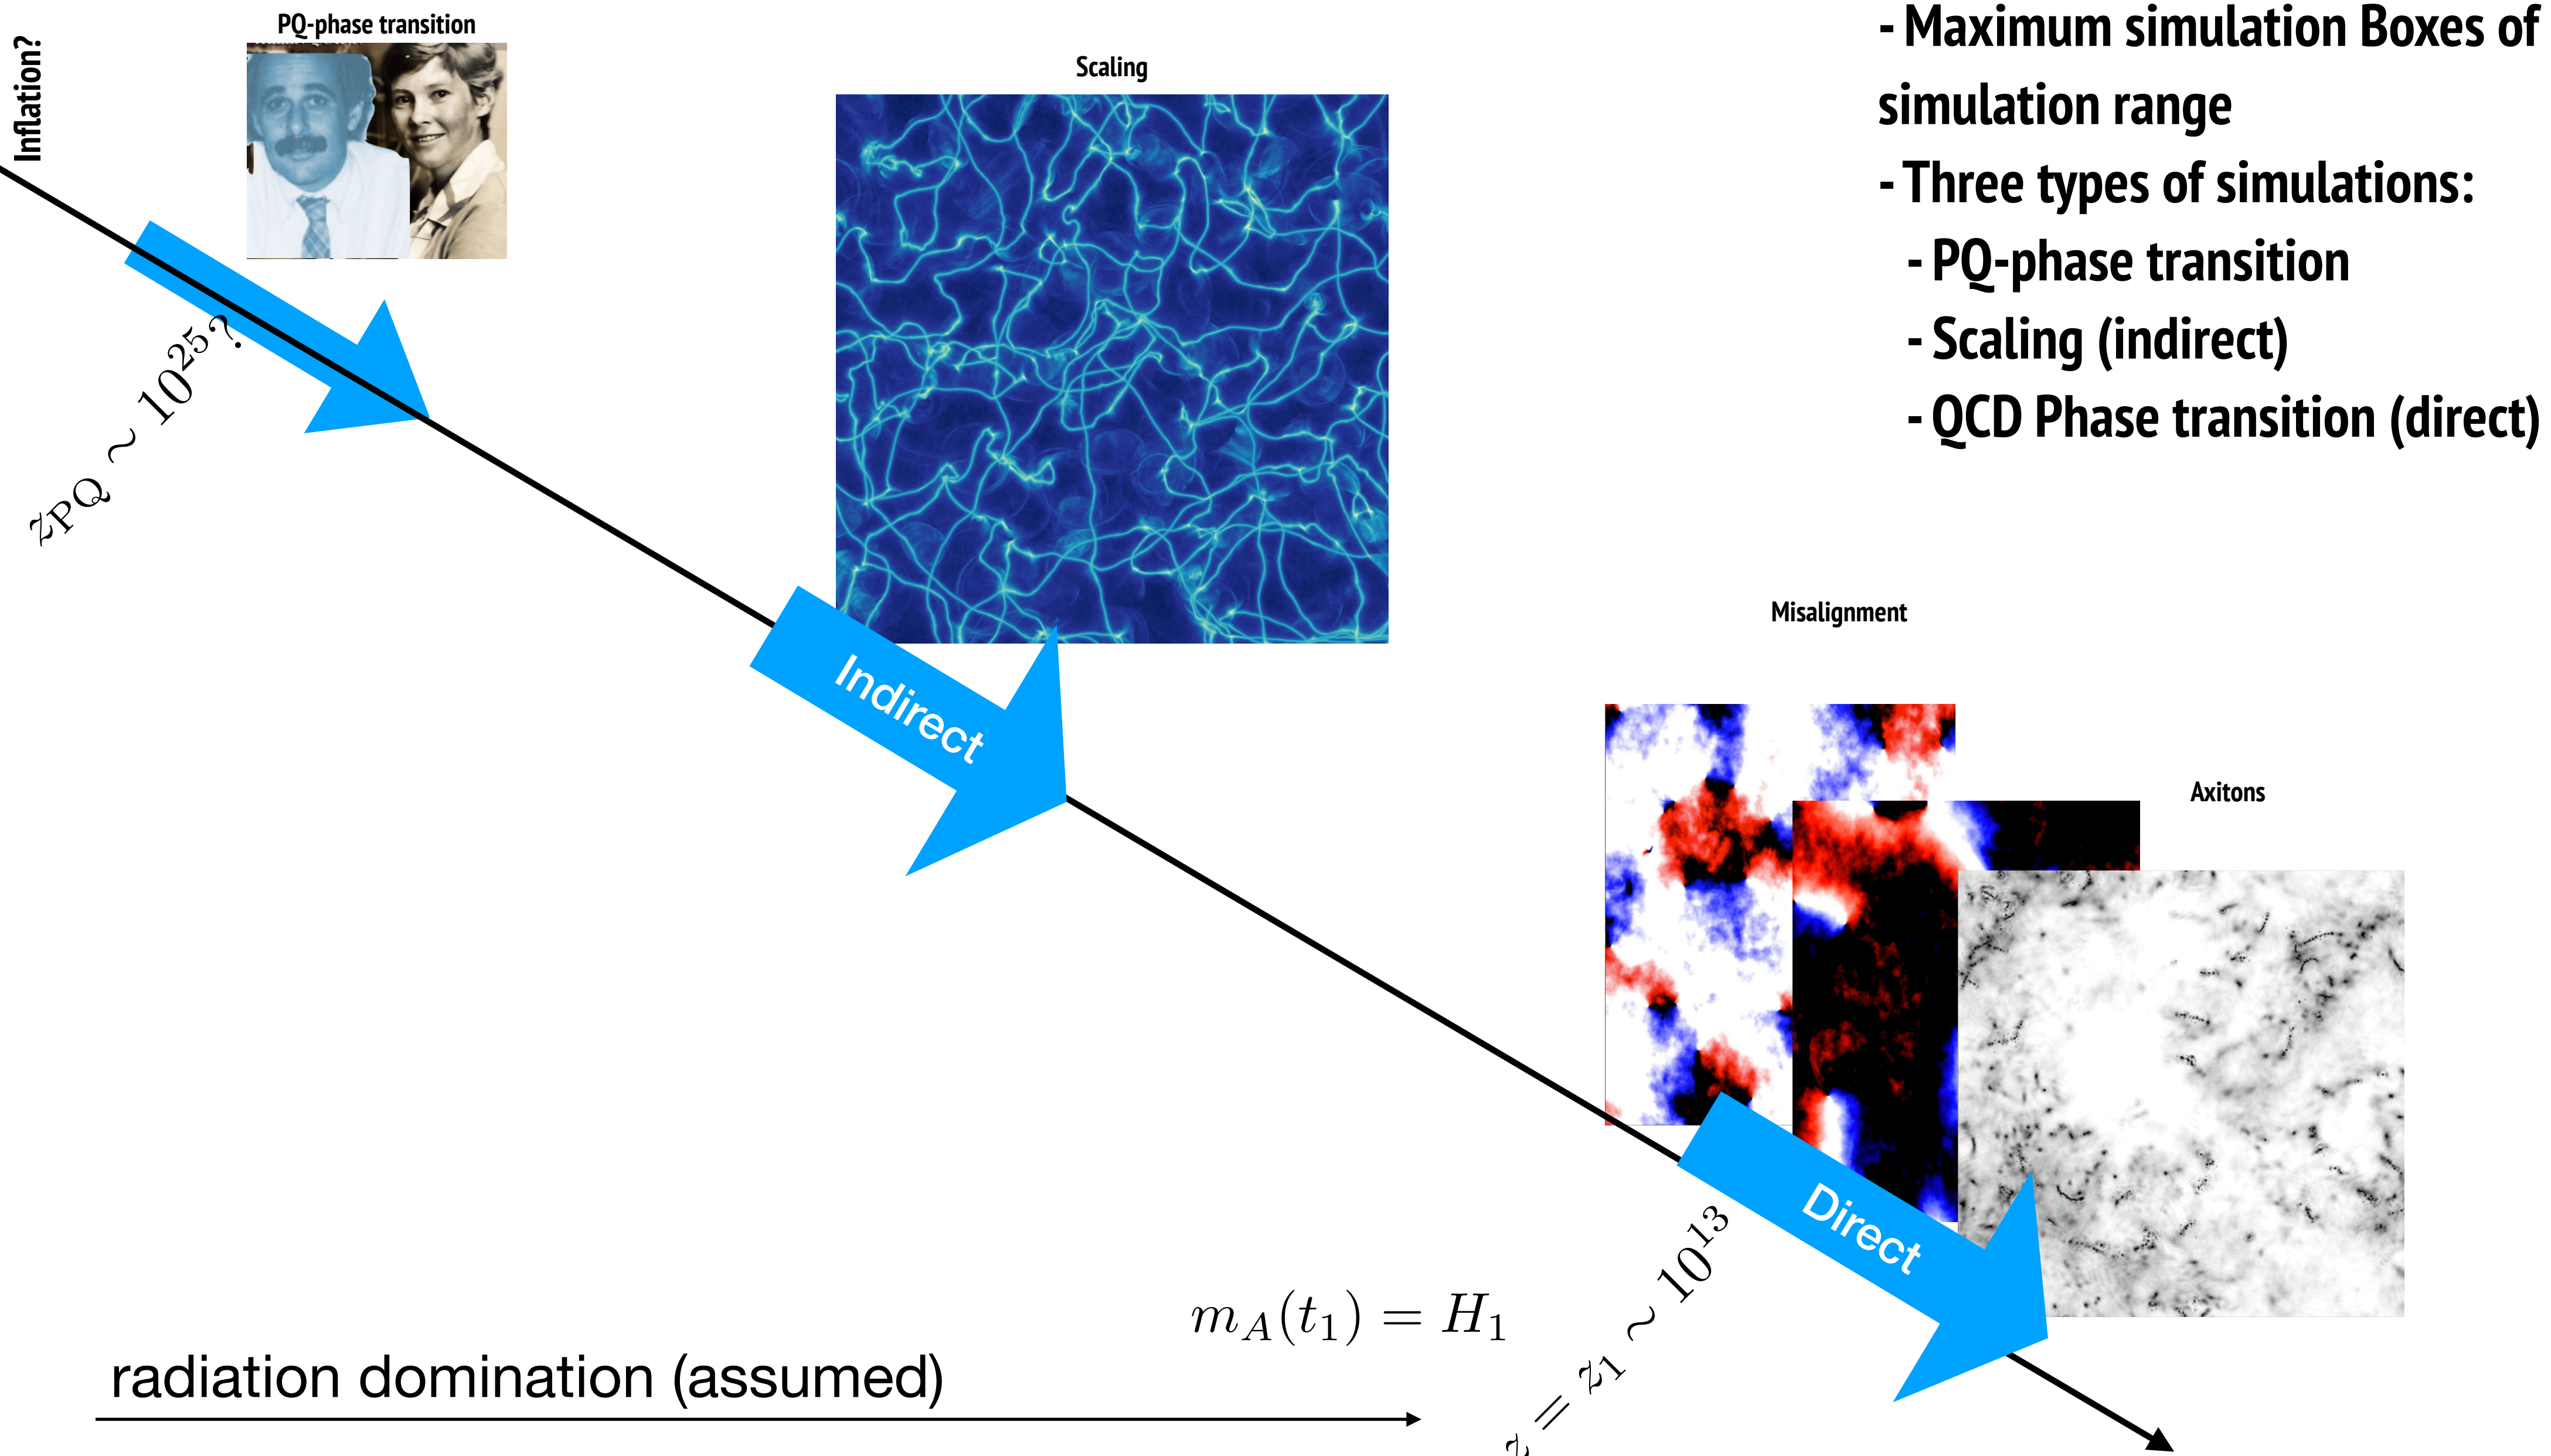

**In-Direct simulation : 1) Simulate to model axion emission from strings, 2) extrapolate the spectrum, 3) count the axions**

*Kawasaki, Gorghetto, Buschmann*

# post-inflationary scenario, simulations

- Maximum simulation Boxes of  $10^4$ , limited simulation range
- Three types of simulations:
  - PQ-phase transition
  - Scaling (indirect)
  - QCD Phase transition (direct)

# Direct simulations

Two approaches:

## Usual U(1) global string

$$\mu = 2\pi \int r dr \left( \partial_r |\varphi|^2 + V(|\varphi|) + \frac{|\varphi|^2}{r^2} \right) \sim v^2 + \pi v^2 \log(vr_{\text{cut}})$$

$$f_A \sim v$$

$$\kappa \sim \log(v/H)$$

Moore, Redondo, Buschmann

**1 extra degree of freedom (radial mode, saxion)**  
**unphysical DW destruction**

PRS trick (enhanced tension at early times)

## Moore tension string

$$\mu \sim 2v^2 + \pi \frac{v^2}{q_1^2 + q_2^2} \log(vr_{\text{cut}})$$

$$f_A \sim v / \sqrt{q_1^2 + q_2^2}$$

$$\kappa \sim 2(q_1^2 + q_2^2)$$

Moore

**2+3 extra degrees of freedom (two higgs, 1 vector field)**

**f<sub>A</sub>/v parametrically suppressed by gauge charges**

**large effective tension**

**no unphysical DW destruction**

PRS trick (enhanced tension at early times)

# Direct simulations

Relatively good agreement of direct simulations

(means... extra energy doesn't convert efficiently into DM axions)  
 "UV energy stays in the UV"

# Indirect simulations: the axion spectrum

- **Goal:** understand how energy is transferred from strings to axions

- **String network density, scaling solution (0(1) string length/Hubble volume)**  $\rho_s = \xi \frac{\mu}{t^2} \left( \sim \frac{\mu \ell}{l^3} \right)_{\ell \sim t} \sim \mathcal{O}(\xi H^2 f_A^2 \kappa)$  *Kibble, Vilenkin*

$$\xi \sim 1 \quad \text{Yamaguchi '99, Hiramatsu '11}$$

Implies an energy loss rate  $\Gamma_{st \rightarrow A} = \frac{\xi \mu}{t^3}$

- **Axion ENERGY** produced at that rate ...  $\dot{\rho}_A + 4H\rho_A = \Gamma_{st \rightarrow A}$

$$\rho_A \sim \frac{1}{2} \langle |\dot{A}|^2 \rangle \sim \mathcal{O}(\xi \kappa H^2 f_A^2)$$

- **BUT Axion NUMBER** is the adiabatic invariant!

- **Axion number depends on the spectrum**  $n_A(t) \sim \int_0^t dt' \left( \frac{R'}{R(t)} \right)^3 \int \frac{dk}{k} \frac{\partial \rho_A}{\partial t \partial k}$

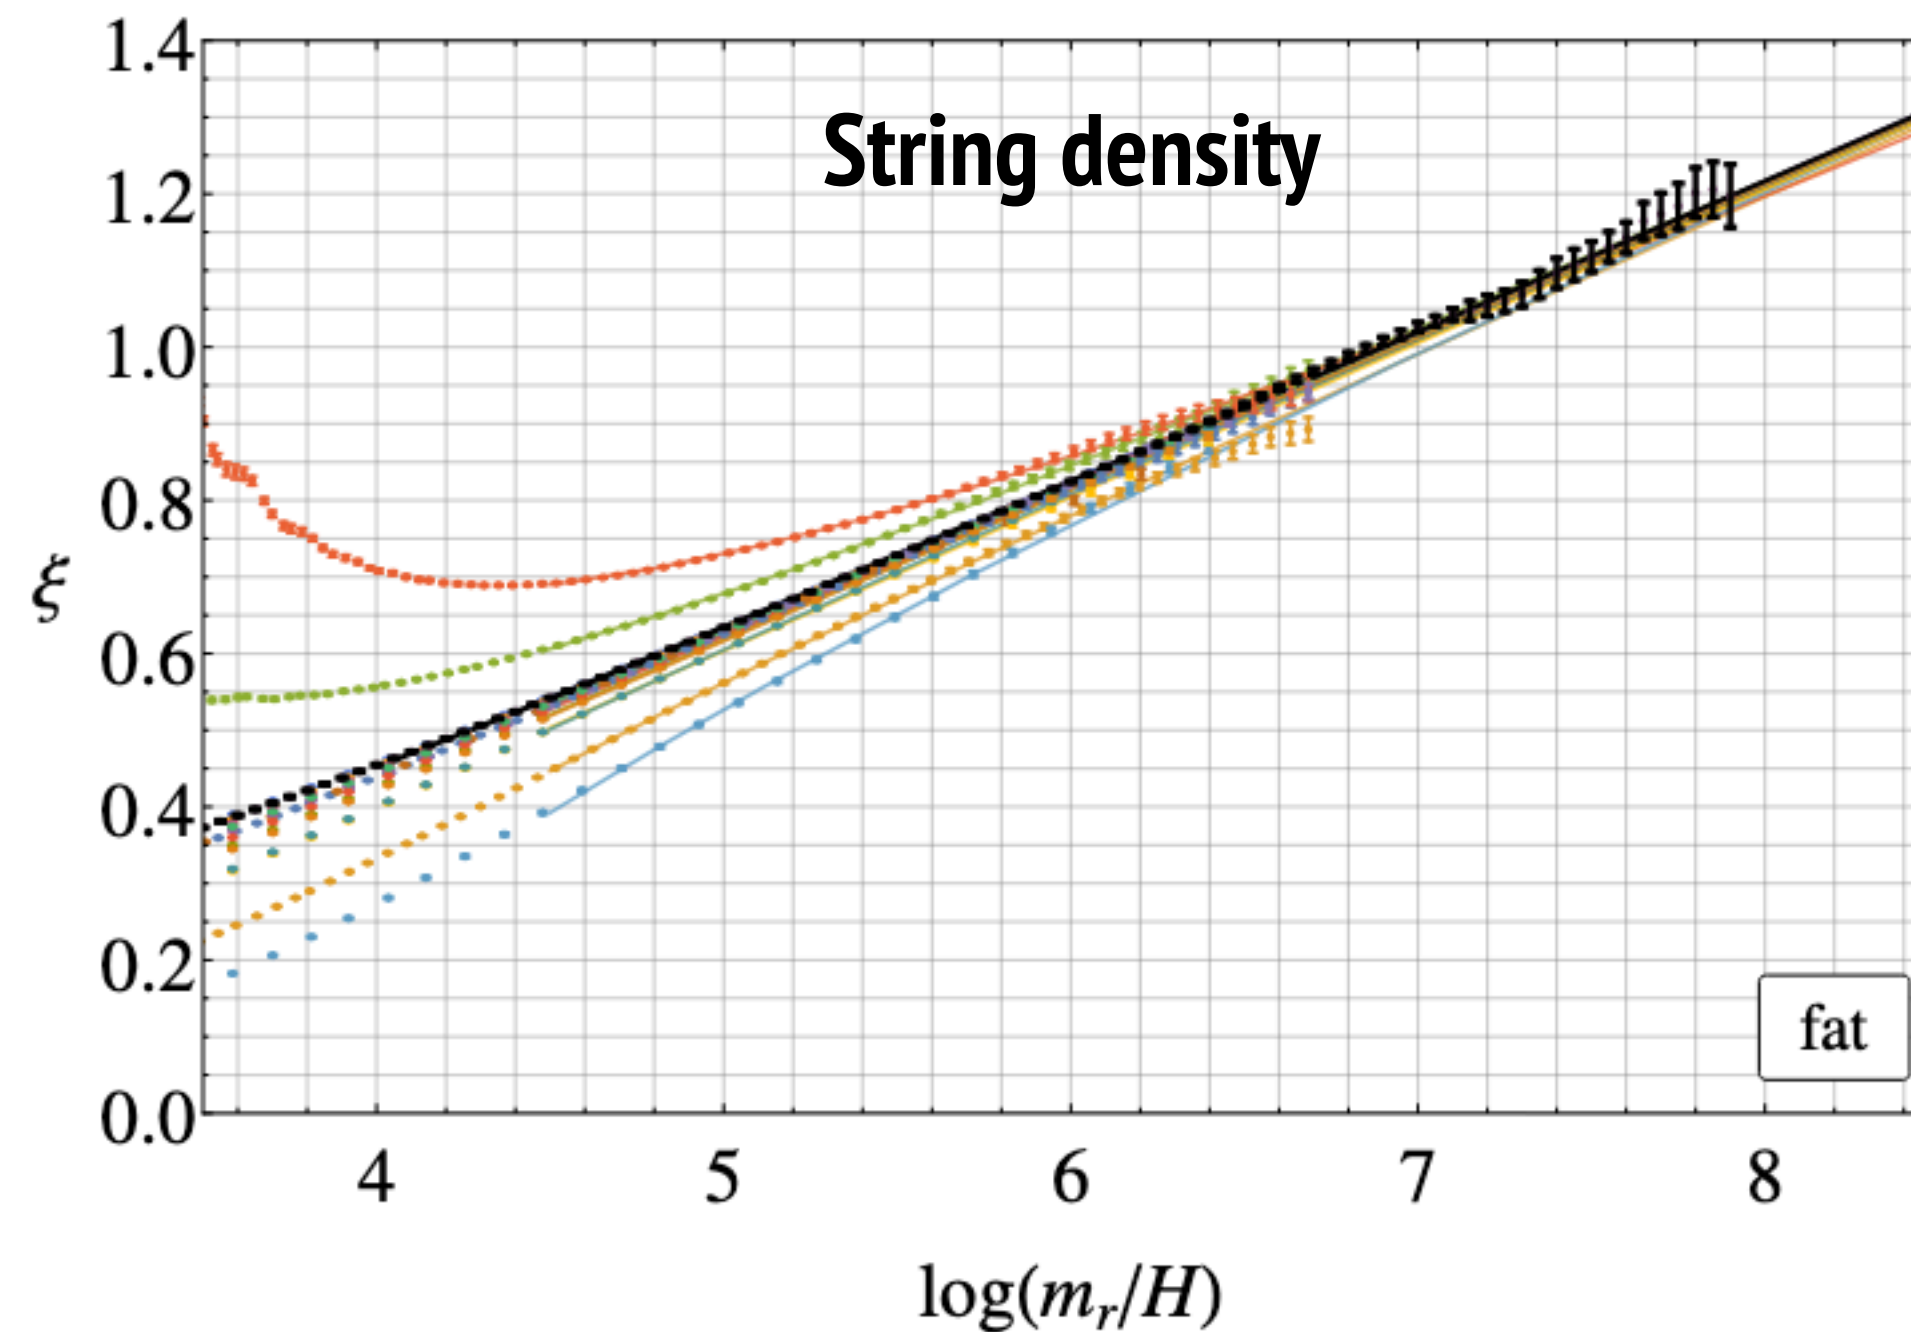

depends on the mean energy

# String network evolution

- Studied in many papers at low tension ( $k < 9$ )
- $O(1)$  with small logarithmic increase *Gorghetto, Viladoro, Hardy*
- Extrapolates to  $O(15)$  *Gorghetto, Viladoro, Hardy20, Buschman 21*
- Small controversy, 1p vel model *Hindmarsh 21*

string-length per  
causal horizon

$\log fA/H$  (distance between strings/string core)

The fraction of the total string length  $\xi/\xi_\infty$  that is contained in loops smaller than  $l$  for different time shots.

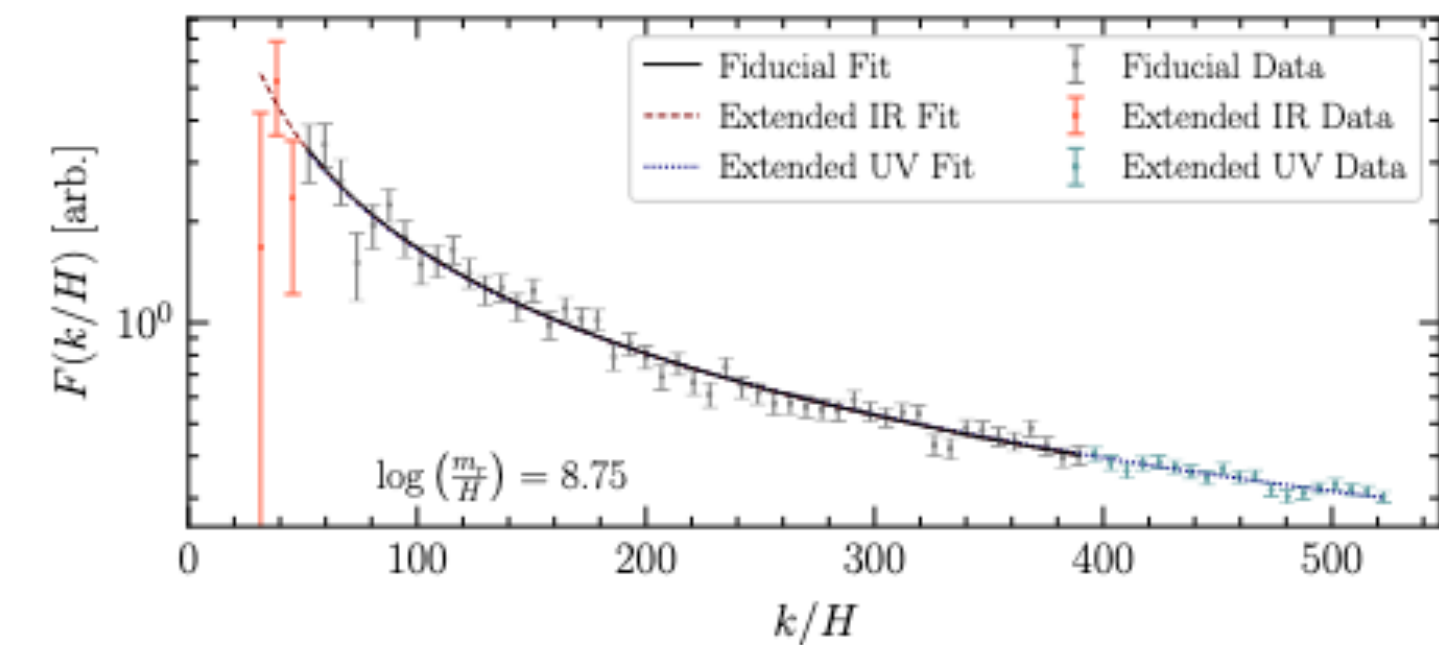

# Spectrum of string radiated axions

Gorghetto, Viladoro, Hardt

- Time-derivative of the spectrum  $F \sim \frac{\partial^2 \rho_a}{\partial t \partial k}$
- Power-law between IR (limited by causality) and UV (fA) cut-offs

$$1/k^q$$

- Several attempts in the literature, differ mostly in :  
**ICs, statistics, and analysis details** *Hiramatsu, VGH, Redondo, Buschman*

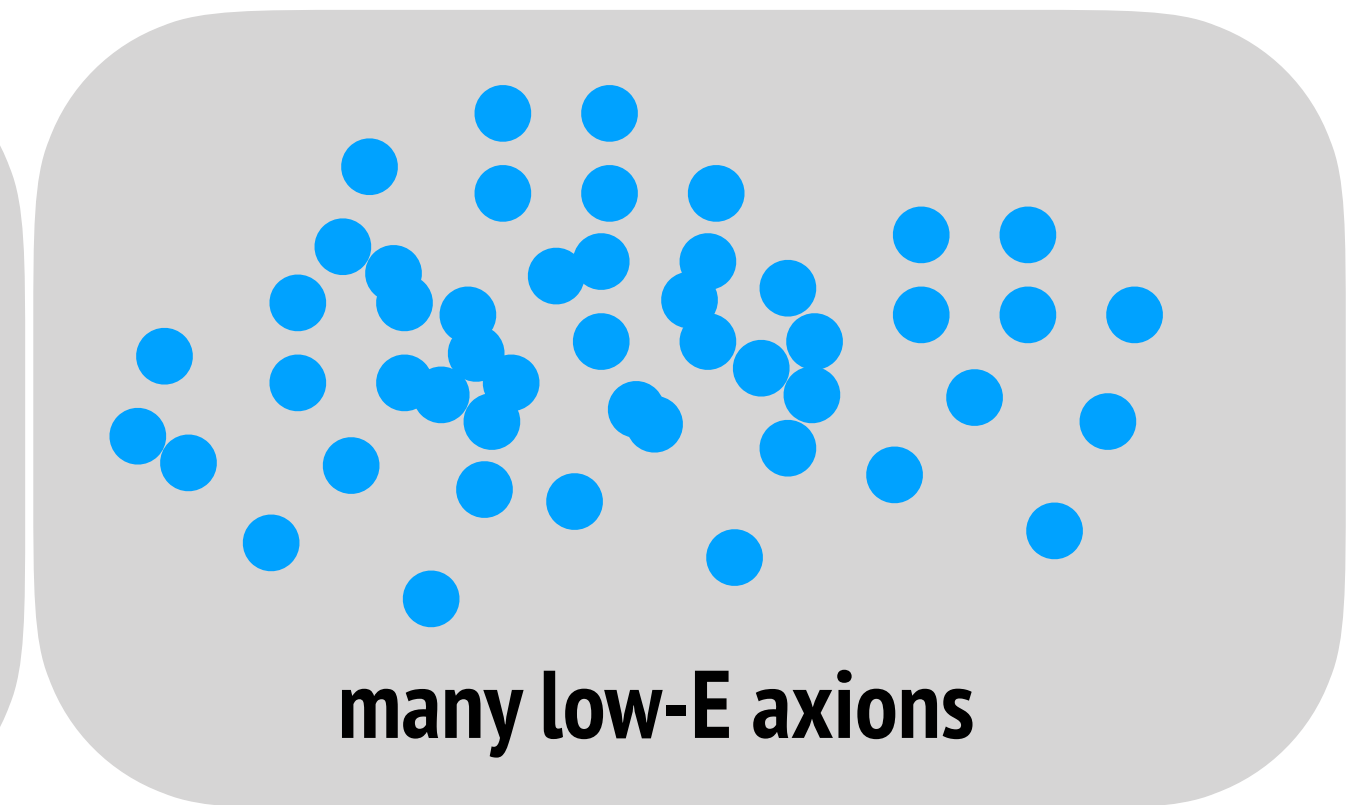

# the impact of q

- Model spectrum like a power law  $1/k^q$

$$n_a(t) \approx \frac{8H\xi(t)\mu_{\text{eff}}(t)}{x_0} \times \begin{cases} 1 - 1/q & q > 1 \\ \frac{1}{\log\left(\frac{m_r}{Hx_0}\right)} & q = 1 \\ \frac{1-q}{q(2q-1)} \left[\frac{Hx_0}{m_r}\right]^{1-q} & \frac{1}{2} < q < 1, \end{cases}$$

$$F[x, y] = \begin{cases} \frac{1}{x_0} \left(\frac{x_0}{x}\right)^q \frac{q-1}{1-\left(\frac{x_0}{y}\right)^{q-1}} & x_0 < x < y \\ 0 & x < x_0 \vee x > y, \end{cases}$$

# the value of $q$

## - VGH 20

- ICs in the attractor solution
- O(100) simulations
- find  $q < 1$  but increasing
- theoretical expectations
- Compatible with similar simulations (in particular mine...)

(Redondo, Saikawa, Vaquero to appear)

## - Buschmann 21

- ++AMR to increase dynamical range!!
- ICs with a PQ phase transition (parameters?)
- 1 huge simulation
- Very conservative analysis
- find  $q \sim 1$  NOT INCREASING
- some theoretical reasoning

# Extrapolation

**VGH 21**

**Buschmann 21**

**typical value direct simulations, strings do not matter**

# Non-linearities at large axion production

- Scaling analysis give a value of  $n_A$  around the QCD phase transition,
- QCD potential is non-linear, DWs destroy string network... how does this affect?
- Leading effects at large  $n_A$  studied by VGH21, strong SQRT reduction
- Very important for VGH21 assumption ( $q \gg 1$ ), less so for Buschmann 21 ( $q \sim 1$ )

# Direct simulations

Very good agreement of direct simulations

# Conclusions

- New generation of numerical simulations are getting closer to tackle the axion DM mass
- Main problem is **dynamical range**
- Direct attempt: **more or less convergent results** (need to reduce errors) [have  $\xi \sim O(1)$ ,  $q < 1$ ],  $k \sim 8-70!$  **UV stays in the UV**
- Indirect attempt:
  - VGH attractor solution suggests  $q \gg 1$  ... although the growing trend could stagnate at  $q=1$  (then why not  $\xi$  too?)
  - Buschmann 21 finds  $q=1$  with **1 simulation** and **different ICs**, **no NL evolution under QCD**
- Need to increase dynamical range, statistics and use similar ICs to be sure of extrapolation.
- Note: Direct attempt is only justified if  $q \lesssim 1$ ,  $\xi \sim O(1)$  by the indirect attempt
