Tracking efficiency

The tracking efficiency is the result of the reconstructed primary particles over generated primary particles.

 $\varepsilon(p_{\rm T}) = \frac{N_{\rm prim, rec}^{\rm MC}(p_{\rm T})}{N_{\rm prim, gen}^{\rm MC}(p_{\rm T})}$

The "real" tracking efficiency for each particle species is a convolution of the particles decay probability and detector effects. The rest tracking efficiency is given by the weighted sum of the rest bulk particle tracking efficiencies:

$$\varepsilon_{rest}(p_{\rm T}) = \sum_{i=e,\mu,\Omega,\Xi} \frac{N_{\rm i}^{\rm MC}(p_{\rm T})}{N_{\rm rest}^{\rm MC}(p_{\rm T})} \varepsilon_i$$

Particle composition correction factor

The data-driven tracking efficiency can be calculated using:

The relative single-particle abundances in Monte

Carlo differ from data.

 $\varepsilon_{incl}(p_{\rm T}) = \sum f_i(p_{\rm T})\varepsilon_i(p_{\rm T})$ $i=\pi,K,p,\Sigma,rest$

For that reason the tracking efficiency is reweighed with measured particle composition.

The single-particle spectra

Instituto de Ciencias Nucleares, UNAM

The measured single-particle spectra in pp collisions at $\sqrt{s_{\rm NN}} = 5.02$ TeV are

shown in the next figures:

★ considering a fit for low- $p_{\rm T}$ because the spectra does not cover the full transverse-momentum range of $p_{\rm T} < 0.5$ GeV.

♦ shown also a power law to $p_{\rm T}$ > 3 GeV.

Construction of Σ^+ and Σ^+ spectra

Instituto de Ciencias Nucleares, UNAM

Since there is no measurement of Σ + and Σ - particles as well as their corresponding antiparticles, their similarity in composition with Λ is exploited to construct a realistic Σ + and Σ - spectrum.

$$\Sigma^+(uus)$$
 $\Sigma^-(dds)$ $\Lambda(uds)$

The procedure uses the following formula:

$$N_{\Sigma^{+/-}}^{const}(p_{\mathrm{T}}) = \frac{N_{\Sigma^{+/-}}^{\mathrm{MC}}(p_{\mathrm{T}})}{N_{\Lambda}^{\mathrm{MC}}(p_{\mathrm{T}})} N_{\Lambda}^{\mathrm{mes}}(p_{\mathrm{T}})$$
