23rd International Workshop on **Radiation Imaging Detectors** 26 - 30 June 2022

Riva del Garda, Italy

Type: Oral

## Event driven Timepix3 hybrid pixel detector for cryo-EM at 200 keV

Monday 27 June 2022 11:30 (20 minutes)

The development of direct pixelated detectors has played a key role in the resolution revolution in which structures of macromolecular complexes are obtained at near-atomic resolution by cryo-EM [1]. Monolithic active pixel sensor (MAPS) detectors are currently widely applied for cryo-EM, however, they have their best performance at 300 keV and have relatively low readout speed. The Timepix3, a hybrid pixel detector (HPD), can operate at very broad energy range (2 - 400 keV) and has an extremely high time resolution (event-driven 1.56 ns).

Previously, we have shown that the incident position of the electron can be predicted at sub-pixel accuracy using convolutional neural networks (CNN), thereby boosting the modulation transfer function (MTF) of experimental knife-edge data both at 200 keV and 300 keV [2]. Here we present the Timepix3 fully integrated in a cryo-EM Single Particle Analysis workflow. We determined its detective quantum efficiency (DQE), an important factor for cryo-EM which is affected by both MTF and noise power spectrum (NPS). Our hard- and soft-ware integration allows for full control of all the factors important for the performance of a detector for a certain application. We studied the effect of deterministic blur to DQE and the final protein single particle analysis (SPA) reconstructions resolution. We could compare results obtained with our workflow with those obtained data collected from the same protein on the same microscope, using a commercial available camera. Our results show that our implementation of the Timepix3 for SPA applications can rival the data obtained with commercial MAPS detector. We discuss the versatility of our detector setup, which allows for a huge range of fluence settings, it could be used to study radiation-damage onset, it could be used both in imaging and diffraction mode, does not require dose-protection, and could be used at the widest possible energy range. Furthermore, we discuss its successor, the Timepix4, which we hope to use for liquid-cell applications as well as cryo-ptychography on biological samples.

We thank Ye Gao and Eve Timlin for providing protein samples. We are grateful to the M4I Microscopy CORE Lab team of FHML Maastricht University for their support and collaboration. We thank Amsterdam Scientific Instruments team members for their support in building and operating the detectors. This research is funded by the Netherlands Organisation for Scientific Research (NWO) in the framework of the Fund New Chemical Innovations, project MOL3DEM, number 731.014.248; European Union's Horizon 2020 Research and Innovation Programme under Grant Agreement No 766970 Q-SORT; this project is co-funded by the PPP Allowance made available by Health Holland, Top Sector Life Sciences & Health, to stimulate public-private partnerships; Alzheimer DE-19082CB, as well as by the Link program from the Province of Limburg, the Netherlands.
