

# Possible consequences of LHC beam losses for CMS

M. Huhtinen

*CERN*

*CH-1211 Geneva, Switzerland*

# Our worries

## **Loss of full beam into one spot**

**Major physical destruction of all components hit**

**Too catastrophic to really worry about**

## **Local loss of full beam but spread in time or space**

**Limited/no physical damage**

**Cumulative damage to detectors ?**

**Damage due to huge dose rate ?**

## **Partial loss of beam or injection failure**

**Probably no physical damage**

**Cumulative damage to detectors ?**

**Damage due to huge dose rate ?**

# Loss of full intensity beam in CMS

**Assume the loss is spread in time/space such that no material is melted/vaporised**

**Normally  $10^9$  pp-interactions per second**

**Beam loss deposits  $3 \times 10^{14}$  energy of protons**

$$\text{Ratio} = \frac{3 \times 10^{14}}{10^9} = 3 \times 10^5$$

**Even a full loss corresponds to cumulative radiation equivalent to only  $\sim 10$  days operation**

# Partial beam loss close to CMS

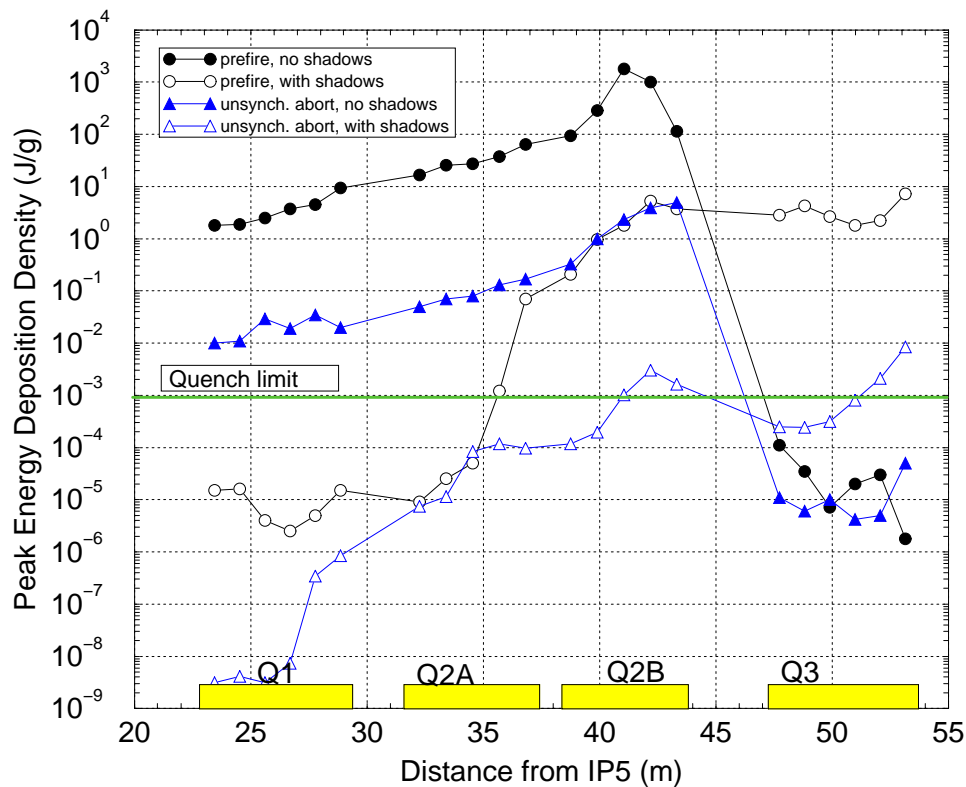

How could it arise ?

**Kicker prefire → unsynchronised abort**

Suggested as accident scenario in 1999 by N. Mokhov

Unsynchronised abort deflects  $\sim 10$  integral bunches

Unless these are captured in IP6 the counterclockwise bunches are lost in the low- $\beta$  of CMS

# Neutron flux & dose from Unsync-abort

Neutrons  $\text{cm}^{-2}$  per accident

Dose Gy per accident

# Rates in CMS Tracker after Unsync-abort

**Duration of unsynchronised abort loss:**  
**260 ns (estimate of 1999)**

## Cumulative dose during 10 years normal operation and one unsynchronised abort

R (cm)	Normal Dose (Gy)	Acc. Dose (Gy)	Time Eq.
4.5	$(8.28 \pm 0.07) \times 10^5$	$1.6 \pm 0.3$	100 s
22	$(6.66 \pm 0.06) \times 10^4$	$(9.4 \pm 1.8) \times 10^{-3}$	7 s
74.5	$7000 \pm 100$	$(1.3 \pm 0.4) \times 10^{-3}$	10 s

**Contribution to integral dose (damage) is negligible**

## Dose during normal operation and during an unsynchronised abort

R (cm)	Norm. Dose rate (Gy/s)	Acc. Dose rate (Gy/s)	× norm.
4.5	$(1.66 \pm 0.01) \times 10^{-2}$	$(6.2 \pm 1.2) \times 10^6$	$4 \times 10^8$
22	$(1.33 \pm 0.01) \times 10^{-3}$	$(3.6 \pm 0.7) \times 10^4$	$3 \times 10^7$
74.5	$(1.40 \pm 0.02) \times 10^{-4}$	$5000 \pm 1500$	$4 \times 10^7$

**Tracker has to survive instantaneous rates many orders of magnitude above normal conditions**

# Neutron flux & dose from 7 TeV on TAS

Neutrons  $\text{cm}^{-2}$  per proton

Dose Gy per proton

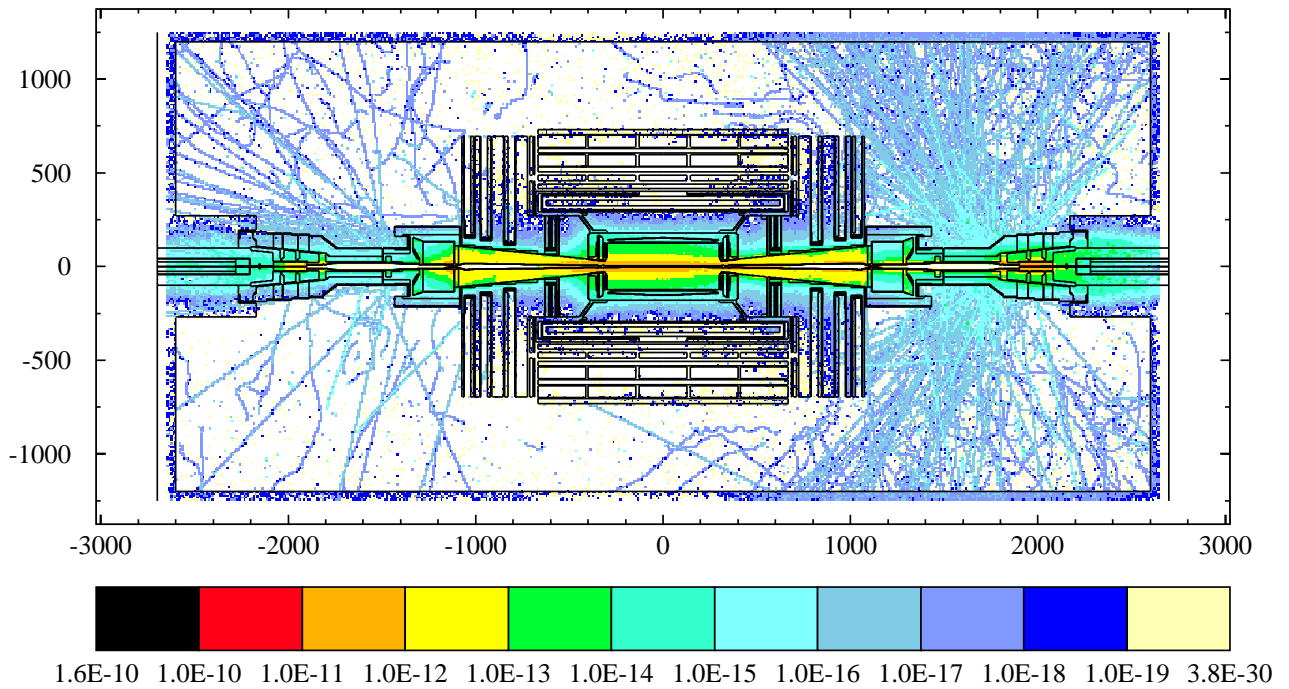

# Neutron flux & dose from 450 GeV on TAS

Neutrons  $\text{cm}^{-2}$  per proton

Dose Gy per proton

# Dose (Gy) in Tracker for 2 loss scenarios

**Unsynchronised abort**

**One 7 TeV proton on TAS**

# "Generic" Accident

## Dose in innermost Si-strip layer of CMS Tracker (R=22 cm)

Loss type	Dose per event	Ratio
<b>Unsynchronised abort</b>	<b>10 mGy</b>	
<b>7 TeV proton on TAS</b>	<b>15 pGy</b>	$7 \times 10^8$
<b>450 GeV proton on TAS</b>	<b>1 pGy</b>	$1 \times 10^{10}$

**Losses directly on the TAS  
worse than  
unsynchronised abort**

**Dose rates up to 1000 times higher if complete  
consecutive bunches lost on TAS**

**An unsynchronised abort we (CMS) just  
have to survive**

**Losses directly on the TAS we might be able  
to detect early and take protective/preventive  
action**

# CMS Beam Condition Monitor (BCM)

**Proposal to install small sensors (diamond) very close to central (Be) beam pipe at about  $z=200$  cm,  $r=4$  cm.**

## Purpose

**Monitor fluctuations of background and react on any significant excess**

**Minor excess in background**

**ramp down detector voltages**

**Major excess background**

**trigger beam abort**

**Anomalies during injection or ramping**

**trigger injection inhibit or abort**

**Provide a log-file with time structure of background close to IP to aid in any **post-mortem analysis** after beam incidents**

# Needed time resolution for BCM

**Have to discriminate beam instabilities  
against background from  $8 \times 10^8$  events per  
second**

**Losses likely to happen on inner triplet or TAS**

**1 proton on TAS gives 0.65 nGy at BCM**

**1s running at  $10^{34}$  gives 31 mGy/s**

**5 protons on TAS  $\equiv$  100 ns normal running**

**Design BCM for  $\sim 100$  ns sampling time to  
have maximum sensitivity for proton losses**

# Beam loss on central Be-pipe

**Seems quite unlikely**

However, some “theoretical” possibilities

**breaking of beam pipe support wire**

**mis-steering of 450 GeV beam during injection**

**Not yet studied, but probably less severe for CMS  
than losses on TAS**

**however**

**An intense beam with small cross section  
could melt or vaporise the beryllium**

**Assume 200  $\mu\text{m}$  spot size, no cascade formation:**

**Melting: 44 bunches**

**Vaporisation: 470 bunches**

**Cascading might decrease these more than factor 10**

# Conclusions

**We do not consider catastrophic point-like beam losses which would physically destroy any material**

**Any beam loss is negligible for cumulative radiation**

**In the (likely) case of an unsynchronised abort the CMS Tracker must survive instantaneous dose rates  $\sim 10^8$  times above normal conditions**

**“Single shot” beam test done in 2002 show that CMS Si-Strip Tracker modules survive such conditions**

**We have done simulations for “generic” worst case accidents: beam particles lost on the TAS**

**CMS will design a dedicated Beam Condition Monitor close to the IP to detect early any losses in IR5**

**This BCM will be connected to the CMS slow control and LHC interlock system to trigger shut-down of CMS or beam abort of the LHC**
