

## Memory-triggered supernova neutrino detection

*Wednesday 8 June 2022 13:45 (15 minutes)*

When a burst of neutrinos from a core-collapse supernova (CCSN) passes by the Earth, it causes a permanent change in the local space-time metric, called the gravitational wave (GW) memory. Long considered unobservable, this effect will be detectable in the near future, at deci-Hertz GW interferometers. I will present a novel idea, where observations of the neutrino GW memory from CCSNe will enable time-triggered searches of supernova neutrinos at megaton (Mt) scale detectors. This combination of a deci-Hz GW detector and a Mt neutrino detector will allow the latter to surpass its current sensitivity limits to detect a nearly background-free sample of  $\sim 3 - 30$  supernova neutrino events per Mt per decade of operation, from large distances ( $\sim 10 - 100$  Mpc), which will open a new avenue to studying supernova neutrinos.
