 - "Hello World!"

Introduction to Optics Design

Goal

The aim of the "Introduction to Optics Design" lecture is three-fold:

- to recall the matrix formalism applied to Linear Optics,
- to use the matrix formalism to perform Linear Optics Design,
- to break the ice for the concepts that will be generalized during the next days.

Theory of the Alternating-Gradient Synchrotron^{*†}

E. D. COURANT AND H. S. SNYDER

Brookhaven National Laboratory, Upton, New York

The equations of motion of the particles in a synchrotron in which the field gradient index

$$n = -(r/B)\partial B/\partial r$$

varies along the equilibrium orbit are examined on the basis of the linear approximation. It is shown that if n alternates rapidly between large positive and large negative values, the stability of both radial and vertical oscillations can be greatly increased compared to conventional accelerators in which n is azimuthally constant and must lie between 0 and 1. Thus aperture requirements are reduced. For practical designs, the improvement is limited by the effects of constructional errors; these lead to resonance excitation of oscillations and consequent instability if $2\nu_x$ or $2\nu_z$ or $\nu_x + \nu_z$ is integral, where ν_x and ν_z are the frequencies of horizontal and vertical betatron oscillations, measured in units of the frequency of revolution.

64-years anniversary of the seminal paper of linear optics.

and for facing the non-linear problems that you will discuss during the following lectures and your professional life.

The three ways

One can consider three typical approaches to introduce the linear optics:

- solving the equation of motion (the historical one),
- using Hamiltonian formalism (opening the horizon to the non-linear optics, see later Lectures),
- using the **linear matrices** (natural choice for the **linear optics design**).

Our reference system I

To describe the motion of a particle in an optics channel, as usual, we fix a coordinate system to define the status of the particle at a given instant t_1 and a set of laws to transform the coordinates of the system from t_1 to a new instant t_2 .

Coordinates

- It is convenient to define the motion along a reference trajectory of the 3D phase space (**reference particle trajectory/orbit**), so to take into account only the variations along that trajectory (Frenet-Serret frame).
- In addition, it is convenient to replace as independent variable the time, t , with the longitudinal position, s , along the reference trajectory/orbit.
- The natural choice for the variables are $(x, \frac{p_x}{p_0}, y, \frac{p_y}{p_0}, z, \frac{p_z}{p_0})$ (**phase-space**, see Hamiltonian approach). p_0 is the amplitude of the reference particle momentum.
- Assuming $p_s \approx p_0$ one can consider also the **trace-space** $(x, x' = \frac{dx}{ds}, y, y' = \frac{dy}{ds}, z, \frac{\Delta p}{p_0})$ (see equation of motion approach).

Linear transformations

We have established phase space $(x, \frac{p_x}{p_0}, y, \frac{p_y}{p_0}, z, \frac{p_z}{p_0})$, now we need to study the particle evolution in there. We assume linear transformation. A system is linear IFF the evolution from the coordinates U to V can be expressed as

$$V = M U$$

where M is a square matrix and does not depend on U .

BUT we are interested only on a special set of linear transformation: the so called symplectic linear transformations, that is the ones associated to a **symplectic matrix**.

Bi-linear transformations

To introduce symplectic matrix we need a short digression on bi-linear transformations.

Let us define the **bi-linear transformation** F as

$$V^T F U. \quad (1)$$

This is a function of two vectors (e.g. U and V).

Let consider, for simplicity, the 1D case, that is, $U = (u_a, u_b)^T$ and $V = (v_a, v_b)^T$.

EXAMPLE: orthogonal matrix

Assuming

$$F = I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad (2)$$

the bilinear transformation I is the dot-product between $V = (v_a, v_b)^T$ and $U = (u_a, u_b)^T$:

$$V^T \underbrace{I}_F U = v_a u_a + v_b u_b.$$

A matrix M preserves the bi-linear transformation I (then the projections) IFF

$$\underbrace{V^T M^T}_{(M V)^T} I M U = V^T I U \rightarrow M^T I M = I,$$

then M is called **orthogonal** matrix.

EXAMPLE: symplectic matrix

Assuming

$$F = \Omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

the bi-linear transformation Ω is proportional to the amplitude of the cross-product between $V = (v_a, v_b)^T$ and $U = (u_a, u_b)^T$:

$$V^T \underbrace{\Omega}_F U = v_a u_b - v_b u_a.$$

that is **proportional to the area** defined by the vectors. A matrix M preserves the bi-linear transformation Ω (related to the cross-product) IFF

$$V^T M^T \Omega M U = V^T \Omega U \rightarrow \boxed{M^T \Omega M = \Omega},$$

then M is called **symplectic** matrix.

EXAMPLE: visualise transformations.

Figure 1: Identity transformation.

EXAMPLE: visualise transformations.

Figure 2: Orthogonal transformation (**dot-product preserved**).

EXAMPLE: visualise transformations.

Figure 3: Symplectic transformation (**cross-product preserved**).

Matrix symplecticity in nD

From 1D this can be generalized to nD and Ω becomes a $2n \times 2n$ matrix:

$$\Omega = \begin{pmatrix} 0 & 1 & & & 0 \\ -1 & 0 & & & \\ & & \ddots & & \\ & & & 0 & 1 \\ 0 & & & -1 & 0 \end{pmatrix}. \quad (3)$$

Example of 2D symplectic matrix:

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}.$$

Domino effect

Properties of symplectic matrices

- If M_1 and M_2 then $M = M_1 M_2$ is symplectic too.
- If M is symplectic then M^T is symplectic.
- Every symplectic matrix is invertible

$$M^{-1} = \Omega^{-1} M^T \Omega \quad (4)$$

and M^{-1} is symplectic.

- A necessary condition for M to be symplectic is that $\det(M) = +1$. This condition is necessary and sufficient for the 1D case. **We will consider 1D case.**
- There are symplectic matrices that are defective, that is it cannot be diagonalized, e.g., $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.

Symplectic matrix and accelerators

Please have a look on this generating set of the symplectic group

$$\underbrace{\begin{pmatrix} G & 0 \\ 0 & \frac{1}{G} \end{pmatrix}}_{\text{thin telescope}}, \underbrace{\begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix}}_{\text{drift}}, \underbrace{\begin{pmatrix} 1 & 0 \\ -\frac{1}{f} & 1 \end{pmatrix}}_{\text{thin quad}}.$$

Among the above matrices you can recognise the one of a L -long drift and thin quadrupole with focal length f .

Conveniently combining drifts and thin quadrupole one can find back the well known matrices for the thick elements.

EXAMPLE: a thick quadrupole I

One can derive the transfer matrix of a thick quadrupole of length L by and normalized gradient K_1 by considering the following limit

$$\lim_n \left[\begin{pmatrix} 1 & 0 \\ -\frac{K_1 L}{n} & 1 \end{pmatrix} \begin{pmatrix} 1 & \frac{L}{n} \\ 0 & 1 \end{pmatrix} \right]^n =$$

$$\begin{pmatrix} \cos(\sqrt{K_1 L}) & \frac{\sin(\sqrt{K_1 L})}{\sqrt{K_1}} \\ -\sqrt{K_1} \sin(\sqrt{K_1 L}) & \cos(\sqrt{K_1 L}) \end{pmatrix}$$

Therefore we now have a correspondence between elements along our machine (drift, bending, quadrupoles, solenoids, ...) and symplectic matrices.

EXAMPLE: a thick quadrupole II

To compute the above limit and, in general, for symbolic computations one can profit of the available symbolic computation tools (e.g., Mathematica™).

Code

```
MD[L_] = {{1, L}, {0, 1}}
{{1, L}, {0, 1}}

MQ[KL_] = {{1, 0}, {-KL, 1}}
{{1, 0}, {-KL, 1}}

FullSimplify[Limit[MatrixPower[MQ[K1 L/n].MD[L/n], n], n -> ∞, Assumptions -> {K1 > 0, L > 0}]]
{{Cos[√K1 L],  $\frac{\sin[\sqrt{K1} L]}{\sqrt{K1}}$ }, {-√K1 Sin[√K1 L], Cos[√K1 L]}}
```

```
FullSimplify[Limit[MatrixPower[MQ[-K1 L/n].MD[L/n], n], n -> ∞, Assumptions -> {K1 > 0, L > 0}]]
{{Cosh[√K1 L],  $\frac{\sinh[\sqrt{K1} L]}{\sqrt{K1}}$ }, {√K1 Sinh[√K1 L], Cosh[√K1 L]}}
```

Tracking in a linear system

Given a sequence of elements $M_1, M_2, \dots M_k$ (the **lattice**), the evolution of the coordinate, X_n , along the lattice for a given particle can be obtained as

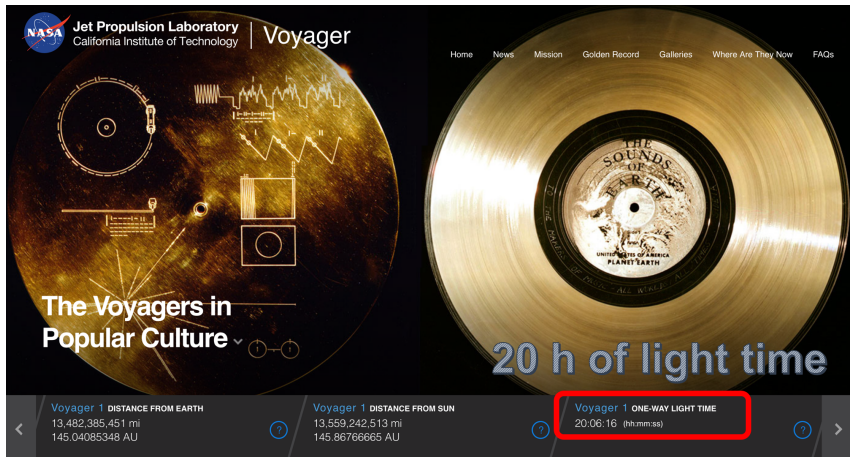

$$X_n = M_n \dots M_1 X_0 \text{ for } n \geq 1. \quad (5)$$

The transport of the particle along the lattice is called **tracking**. The tracking on a linear system is trivial and boring. . .

In the following we will decompose the trajectory of the single particle in term of invariant of the motion and properties of the lattice, and via those properties we will describe the statistical evolution of an ensemble of particles.

So instead of tracking an ensemble we will concentrate to solve the properties of the lattice.

Starting a long journey...

Voyager 1 is the Man-built object farther away from Earth
 ≈ 20 light-hours.

Periodic lattice and stability I

We study now the motion of the particles in a periodic lattice, that is a lattice constituted by an indefinite repetition of the same basic C -long period M_{OTM} , the so-called One-Turn-Map:

$$M_{OTM}(s_0) = M_{OTM}(s_0 + C).$$

From Eq. 5 we get

$$X_n = M_{OTM}^n X_0$$

and we study the property of M_{OTM} to have stable motion in the lattice, that is

$$|X_n| < |\hat{X}| \text{ for all } X_0 \text{ and } n.$$

In other words, we need to study the if all the elements of the M_{OTM}^n stay bounded.

Periodic lattice and stability II

If M_{OTM} can be expressed as a Diagonal-factorization

$$M_{OTM} = P \underbrace{\begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}}_D P^{-1},$$

after m -turns, it yields that

$$M_{OTM}^m = \underbrace{PDP^{-1}}_1 \times \underbrace{PDP^{-1}}_2 \times \cdots \times \underbrace{PDP^{-1}}_m = PD^m P^{-1}.$$

Therefore the stability depends only on the eigenvalues of M_{OTM} .

Note that if V is an eigenvector also kV , $k \neq 0$ is an eigenvector. Therefore **P is not uniquely defined**: we chose it such that $\det(P) = -i$ and $P_{11} = P_{12}$.

Periodic lattice and stability III

- For a real matrix the eigenvalues, if complex, appear in complex conjugate pairs.
- For a symplectic matrix M_{OTM}

$$\prod_i^{2n} \lambda_i = 1$$

where λ_i are the eigenvalues of M_{OTM} .

- Therefore for 2x2 symplectic matrix the eigenvalues can be written as $\lambda_1 = e^{i\mu}$ and $\lambda_2 = e^{-i\mu} \rightarrow D^m = D(m\mu)$.

If μ is real then the motion is stable we can define the fractional tune of the periodic lattice as $\frac{\mu}{2\pi}$.

R-factorization of the M_{OTM} I

The Diagonal-factorization is convenient to check the stability but not to visualize the turn-by-turn phase space evolution of the particle. To do that it is convenient to consider the Rotation-factorization

$$M_{OTM} = \bar{P} \underbrace{\begin{pmatrix} \cos \mu & \sin \mu \\ -\sin \mu & \cos \mu \end{pmatrix}}_{R(\mu) \text{ is orthogonal}} \bar{P}^{-1}. \quad (6)$$

This is very important since implies that the M_{OTM} is similar to a rotation in phase space (see Hannes and Yannis's lectures).

R-factorization of the M_{OTM} II

To go from Diagonal to Rotation-factorization we note that

$$\underbrace{\begin{pmatrix} \cos \mu & \sin \mu \\ -\sin \mu & \cos \mu \end{pmatrix}}_{R(\mu)} = \underbrace{\begin{pmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{i}{\sqrt{2}} & -\frac{i}{\sqrt{2}} \end{pmatrix}}_{S^{-1}} \underbrace{\begin{pmatrix} e^{i\mu} & 0 \\ 0 & e^{-i\mu} \end{pmatrix}}_{D(\mu)} \underbrace{\begin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{i}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{i}{\sqrt{2}} \end{pmatrix}}_S$$

and therefore

$$R^m = R(m\mu),$$

$$M_{OTM} = \underbrace{P S}_{\bar{P}} \underbrace{S^{-1} D S}_R \underbrace{S^{-1} P^{-1}}_{\bar{P}^{-1}}$$

We note that $\det(\bar{P}) = 1$.

Twiss-factorization of M_{OTM} I

We note that

$$R(\mu) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cos \mu + \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \sin \mu,$$

yielding the, so called, **Twiss**-factorization

$$M_{OTM} = \underbrace{\bar{P} I \bar{P}^{-1}}_I \cos \mu + \underbrace{\bar{P} \Omega \bar{P}^{-1}}_J \sin \mu$$

Where J has three properties: $\det(J) = 1$, $J_{11} = -J_{22}$, $J_{12} > 0$.

Code: J properties

```
Omega = {{0, 1}, {-1, 0}};
Pbar = {{m11, m12}, {m21, m22}};
Pbar.Omega.Inverse[Pbar] /. {-m12 m21 + m11 m22 -> 1}
{{-m11 m21 - m12 m22, m11^2 + m12^2}, {-m21^2 - m22^2, m11 m21 + m12 m22}}
```

Twiss-factorization of M_{OTM} II

Therefore the following parametric expression has been proposed

$$J = \begin{pmatrix} \alpha & \overbrace{\beta}^{>0} \\ -\underbrace{\frac{1+\alpha^2}{\beta}}_{\gamma>0} & -\alpha \end{pmatrix}$$

defining the **Twiss parameters** of the lattice at the start of the sequence M_{OTM} . It is very important to note that they are not depending on m since

$$M_{OTM}^m = I \cos(m\mu) + J \sin(m\mu)$$

In other words the **Twiss parameters are periodic** (compare to Floquet theorem).

Twiss-factorization of M_{OTM} III

From the definition of J follows, $J = \bar{P}\Omega\bar{P}^{-1}$, the one of

$$\bar{P} = \begin{pmatrix} \sqrt{\beta} & 0 \\ -\frac{\alpha}{\sqrt{\beta}} & \frac{1}{\sqrt{\beta}} \end{pmatrix} = \begin{pmatrix} \sqrt{\beta} & 0 \\ 0 & \frac{1}{\sqrt{\beta}} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\frac{\alpha}{\sqrt{\beta}} & 1 \end{pmatrix}$$

We note that by choosing $\det P = -i$ we got $\det \bar{P} = 1$ that is we expressed M as the product of orthogonal and symplectic matrices.

and

$$P = \bar{P}S^{-1} = \begin{pmatrix} \sqrt{\frac{\beta}{2}} & \sqrt{\frac{\beta}{2}} \\ \frac{-\alpha+i}{\sqrt{2\beta}} & \frac{-\alpha-i}{\sqrt{2\beta}} \end{pmatrix}.$$

Where do we stand?

Given a symplectic $M_{OTM}(s)$, if diagonalizable, we can study three equivalent periodic problems

- $M_{OTM}(s)^m = P D(m\mu) P^{-1}$,
- $M_{OTM}(s)^m = \bar{P} R(m\mu) \bar{P}^{-1}$,
- $M_{OTM}(s)^m = I \cos(m\mu) + J \sin(m\mu)$.

The previous factorizations allow us to reduce the power of a matrix to an algebraic multiplication ($m\mu$). We expressed P , \bar{P} and J as function of β and α parameters.

→ IMPORTANT FOR LATTICE STABILITY ←

Code

From $M_{OTM}(s)$ compute D (check stability) and P (force $\det(P) = -i$, $P_{11} = P_{12}$), then $\bar{P} = PS$ and $J = \bar{P}\Omega\bar{P}^{-1}$. You therefore get the fractional tune and the Twiss parameters at s_0 .

$M_{OTM}(s_0)$ and $M_{OTM}(s_1)$

$M_{OTM}(s)$ is a function of s : are Q , β and α all s -function?

Given a C -long periodic lattice and two longitudinal positions s_0 and s_1 ($s_1 > s_0$), the transformation from s_0 to $s_1 + C$ can be expressed as

$$\begin{array}{ccccc} s_0 & \longrightarrow & s_1 & \longrightarrow & s_1 + C \\ s_0 & \longrightarrow & s_0 + C & \longrightarrow & s_1 + C \end{array}$$

$$M_{OTM}(s_1) M = M M_{OTM}(s_0)$$

where M is the transformation from s_0 to s_1 . This implies

$$M_{OTM}(s_1) = M M_{OTM}(s_0) M^{-1}$$

- the matrices $M_{OTM}(s_1)$ and $M_{OTM}(s_2)$ are similar.
- same eigenvalues: the M_{OTM} is s -dependent but the Q is not.

β and α transport I

On the other hand we observe that β and α are s-dependent function and we have:

$$M_{OTM}(s_1) = M M_{OTM}(s_0) M^{-1} = M (I \cos \mu + J(s_0) \sin \mu) M^{-1},$$

therefore

$$\underbrace{\begin{pmatrix} \alpha(s_1) & \beta(s_1) \\ -\gamma(s_1) & -\alpha(s_1) \end{pmatrix}}_{J(s_1)} = M \underbrace{\begin{pmatrix} \alpha(s_0) & \beta(s_0) \\ -\gamma(s_0) & -\alpha(s_0) \end{pmatrix}}_{J(s_0)} M^{-1}.$$

β and α transport II

To simplify from a computational point of view the Eq. 7 we can use the Eq. 4 (inverse of a symplectic matrix) and this yields

$$\begin{pmatrix} \alpha(s_1) & \beta(s_1) \\ -\gamma(s_1) & -\alpha(s_1) \end{pmatrix} \Omega^{-1} = M \begin{pmatrix} \alpha(s_0) & \beta(s_0) \\ -\gamma(s_0) & -\alpha(s_0) \end{pmatrix} \Omega^{-1} M^T,$$

that is

$$\underbrace{\begin{pmatrix} \beta(s_1) & -\alpha(s_1) \\ -\alpha(s_1) & \gamma(s_1) \end{pmatrix}}_{J(s_1) \Omega^{-1}} = M \underbrace{\begin{pmatrix} \beta(s_0) & -\alpha(s_0) \\ -\alpha(s_0) & \gamma(s_0) \end{pmatrix}}_{J(s_0) \Omega^{-1}} M^T. \quad (7)$$

EXAMPLE: the β -function in a drift

To compute the Twiss parameters in a drift we can simply apply the previous equation

$$\begin{pmatrix} \beta(s) & -\alpha(s) \\ -\alpha(s) & \gamma(s) \end{pmatrix} = \begin{pmatrix} 1 & s \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \beta_0 & -\alpha_0 \\ -\alpha_0 & \gamma_0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ s & 1 \end{pmatrix}$$

yielding

$$\beta(s) = \beta_0 - 2\alpha_0 s + \gamma_0 s^2$$

and

$$\alpha(s) = \alpha_0 - \gamma_0 s.$$

→ IMPORTANT FOR INSERTIONS←

The differential relation between α and β I

In order to see differential relation with the matrix formalism we consider the general ΔM matrix for the infinitesimal offset, Δs ,

$$\Delta M = \begin{pmatrix} 1 & \Delta s \\ -K(s)\Delta s & 1 \end{pmatrix}.$$

Note that ΔM is symplectic only for $\Delta s \rightarrow 0$.

Then we have

$$\underbrace{\begin{pmatrix} \beta(s + \Delta s) & -\alpha(s + \Delta s) \\ -\alpha(s + \Delta s) & \gamma(s + \Delta s) \end{pmatrix}}_{J(s + \Delta s)\Omega^{-1}} = \Delta M \underbrace{\begin{pmatrix} \beta(s) & -\alpha(s) \\ -\alpha(s) & \gamma(s) \end{pmatrix}}_{J(s)\Omega^{-1}} \Delta M^T.$$

The differential relation between α and β II

From that we have that

$$\lim_{\Delta s \rightarrow 0} \frac{J(s + \Delta s) - J(s)}{\Delta s} \Omega^{-1} = \begin{pmatrix} \beta'(s) & -\alpha'(s) \\ -\alpha'(s) & \gamma'(s) \end{pmatrix}$$

where we used standard notation $\frac{d\cdot}{ds} = \cdot'$. One gets

$$\begin{aligned} \beta'(s) &= -2\alpha(s) \\ \alpha'(s) &= -\gamma + K(s)\beta(s). \end{aligned}$$

Replacing α and γ in the latter equation with functions of β we get the **non-linear differential equation**:

$$\boxed{\frac{\beta''\beta}{2} - \frac{\beta'^2}{4} + K\beta^2 = 1.}$$

EXAMPLE: from matrices to Hill's equation

Following the notation already introduced

$$X(s + \Delta s) = \Delta M X(s)$$

with $X(s) = (x(s), \frac{p_x(s)}{p_0})^T \underset{p_0 \approx p_s}{\approx} (x(s), x'(s))^T$, therefore

$$X'(s) = \begin{pmatrix} x'(s) \\ x''(s) \end{pmatrix} = \lim_{\Delta s \rightarrow 0} \frac{X(s + \Delta s) - X(s)}{\Delta s} = \begin{pmatrix} x'(s) \\ -K(s)x(s) \end{pmatrix}$$

we find back the **Hill's equation**

$$\boxed{x''(s) + K(s)x(s) = 0.}$$

Where do we stand?

- We learnt how to propagate via linear matrices the initial Twiss parameters along the machine.
- We also retrieved several differential relations between α and β , β and K , and X and K : these are, in general, **not practical for computations**.
- The next question is, moving from the lattice to the particle, is there an invariant of the motion?

Courant-Snyder invariant I

Given a particle with coordinate X we can observe that the quantity

$$\boxed{X^T \Omega J^{-1} X}$$

is an invariant of the motion: it is called the **Courant-Snyder invariant**, J_{CS} . In fact from Eq. 7

$$X_1^T \Omega J_1^{-1} X_1 = X_0^T M^T (M J_0 \Omega^{-1} M^T)^{-1} M X_0 = X_0^T \Omega J_0^{-1} X_0$$

Code: find back the CS invariant in the trace-space

```
J = {{α, β}, {-γ, -α}};
FullSimplify[{{x, x'}}.{{0, 1}, {-1, 0}}.Inverse[J].{{x}, {x'}}] /. β γ - α² → 1
{{x² γ + 2 x α x' + β (x')²}}
```

Courant-Snyder invariant II

In the normalized phase-space, remembering that $X = \bar{P} \tilde{X}$, we have

$$X^T \Omega J^{-1} X = \tilde{X}^T \underbrace{\bar{P}^T \Omega J^{-1} \bar{P}}_I \tilde{X} = \tilde{X}^T \tilde{X}$$

that is the J_{CS} is the square of the circle radius defined by the particle initial condition.

This normalized phase-space is also called action-angle phase space. **The particle action J_H is defined as $J_{CS}/2$.**

What about the phase $\mu(s)$? I

What is the $\Delta\mu$ introduced by a linear matrix $M = \begin{pmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{pmatrix}$?

In normalized space the transport from s to $s + \Delta s$ does not change J_{CS} but the angle by $\Delta\mu = \mu(s + \Delta s) - \mu(s)$.

To compute it we move to the normalized phase-space

$$X(s) = \bar{P}(s) \tilde{X}(s) \text{ and } X(s + \Delta s) = \bar{P}(s + \Delta s) \tilde{X}(s)$$

and from

$$X(s + \Delta s) = M X(s),$$

it yields

$$\tilde{X}(s + \Delta s) = \bar{P}(s + \Delta s)^{-1} M \bar{P}(s) \tilde{X}(s) = \begin{pmatrix} \cos \Delta\mu & \sin \Delta\mu \\ -\sin \Delta\mu & \cos \Delta\mu \end{pmatrix} \tilde{X}(s).$$

What about the phase $\mu(s)$? II

That is

$$\tan \Delta\mu = \frac{\sin \Delta\mu}{\cos \Delta\mu} = \frac{m_{12}}{m_{11} \beta(s) - m_{12} \alpha(s)}.$$

It does depend only on β and α in s !

Code: derivation of $\Delta\mu$

```
Pbar0 = {{sqrt(beta0), 0}, {-alpha0/sqrt(beta0), 1/sqrt(beta0)}};
Pbar1 = {{sqrt(beta1), 0}, {-alpha1/sqrt(beta1), 1/sqrt(beta1)}};
M = {{m11, m12}, {m21, m22}};
FullSimplify[Inverse[Pbar1].M.Pbar0]
```

$$\left\{ \left\{ \frac{-m_{12} \alpha_0 + m_{11} \beta_0}{\sqrt{\beta_0} \sqrt{\beta_1}}, \frac{m_{12}}{\sqrt{\beta_0} \sqrt{\beta_1}} \right\}, \left\{ \frac{-m_{12} \alpha_0 \alpha_1 + m_{11} \alpha_1 \beta_0 - m_{22} \alpha_0 \beta_1 + m_{21} \beta_0 \beta_1}{\sqrt{\beta_0} \sqrt{\beta_1}}, \frac{m_{12} \alpha_1 + m_{22} \beta_1}{\sqrt{\beta_0} \sqrt{\beta_1}} \right\} \right\}$$

EXAMPLE 1: $\mu(s)$ differential equation

If $M = \begin{pmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{pmatrix} = \Delta M = \begin{pmatrix} 1 & \Delta s \\ -K(s)\Delta s & 1 \end{pmatrix}$ then one gets

$$\mu' = \lim_{\Delta s \rightarrow 0} \frac{\tan \Delta \mu}{\Delta s} = \lim_{\Delta s \rightarrow 0} \frac{1}{\beta(s) - \alpha(s) \Delta s} \Delta s = \frac{1}{\beta(s)},$$

that is the well know expression

$$\mu(s) = \int_{s_0}^s \frac{1}{\beta(\sigma)} d\sigma + \mu(s_0).$$

EXAMPLE 2: Betatron oscillation I

How we describe a betatronic oscillation from s_1 to s_2 in terms of Twiss parameters and initial conditions?

It is easy by transforming the vector X in the normalized phase space in s_1 , moving it from s_1 to s_2 in the normalized space (pure rotation of the phase μ_{12}) and back transform it in the original phase space.

EXAMPLE 2: Betatron oscillation II

Code

```

Pbar1 = {{sqrt( $\beta_1$ ), 0}, {- $\frac{\alpha_1}{\sqrt{\beta_1}}$ ,  $\frac{1}{\sqrt{\beta_1}}$ }};
Pbar2 = {{sqrt( $\beta_2$ ), 0}, {- $\frac{\alpha_2}{\sqrt{\beta_2}}$ ,  $\frac{1}{\sqrt{\beta_2}}$ }};
R = {{Cos[ $\phi$ ], Sin[ $\phi$ ]}, {-Sin[ $\phi$ ], Cos[ $\phi$ ]}};
FullSimplify[Pbar2.R.Inverse[Pbar1]]
{{ $\frac{\sqrt{\beta_2} (\text{Cos}[\phi] + \alpha_1 \text{Sin}[\phi])}{\sqrt{\beta_1}}$ ,  $\sqrt{\beta_1} \sqrt{\beta_2} \text{Sin}[\phi]$ }, {- $\frac{(-\alpha_1 + \alpha_2) \text{Cos}[\phi] + \text{Sin}[\phi] + \alpha_1 \alpha_2 \text{Sin}[\phi]}{\sqrt{\beta_1} \sqrt{\beta_2}}$ ,  $\frac{\sqrt{\beta_1} (\text{Cos}[\phi] - \alpha_2 \text{Sin}[\phi])}{\sqrt{\beta_2}}$ }}

```

$$\begin{aligned}
 M &= \bar{P}(s_2) R(\mu_{12}) \bar{P}(s_1)^{-1} = \\
 &= \begin{pmatrix} \sqrt{\frac{\beta_2}{\beta_1}} (\cos \mu_{12} + \alpha_1 \sin \mu_{12}) & \sqrt{\beta_1 \beta_2} \sin \mu_{12} \\ \frac{\alpha_1 - \alpha_2}{\sqrt{\beta_1 \beta_2}} \cos \mu_{12} - \frac{1 + \alpha_1 \alpha_2}{\sqrt{\beta_1 \beta_2}} \sin \mu_{12} & \sqrt{\frac{\beta_1}{\beta_2}} (\cos \mu_{12} - \alpha_2 \sin \mu_{12}) \end{pmatrix}
 \end{aligned}$$

EXAMPLE 3: Solution of Hill's equation

How we describe a betatronic oscillation in machine considering a J_{CS} and phase μ_0 ? This is a special case of the previous one. With the J_{CS} and phase μ_0 we are already in the normalized phase space, therefore we need only to rotate by $\mu(s)$ and back transform it in the original phase space.

$$\begin{aligned} X(s) &= \bar{P}(s) \begin{pmatrix} \sqrt{J_{CS}} \cos(\mu + \mu_0) \\ -\sqrt{J_{CS}} \sin(\mu + \mu_0) \end{pmatrix} = \\ &= \begin{pmatrix} \sqrt{J_{CS}\beta(s)} \cos(\mu + \mu_0) \\ -\sqrt{\frac{J_{CS}}{\beta(s)}} [\alpha(s) \cos(\mu + \mu_0) + \sin(\mu + \mu_0)] \end{pmatrix} \end{aligned}$$

where one recognizes the solutions of the Hill's equation.

Computing the closed orbit

Up to now we assumed that the closed orbit (CO) corresponded to the reference orbit. This is not always true.

Assuming a $M_{OTM}(s_0)$ and a single thin kick Θ at s_0 (independent from X_n) we can write

$$X_{n+1}(s_0) = M_{OTM}(s_0) X_n(s_0) + \Theta.$$

In the 1D case Θ can represent a kick of a dipole correction or misalignment of a quadrupole ($\Theta = (0, \theta)^T$). The closed orbit solution can be retrieved imposing $V_{n+1} = V_n$ (fixed point), yielding

$$X_n(s_0) = (I - M_{OTM}(s_0))^{-1} \Theta(s_0).$$

Please note that the CO is discontinuous at s_0 so the previous formula refers to the CO after the kick. In presence of multiple $\Theta(s_i)$ one can sum the single contributions along s .

EXAMPLE: from the CO matrix to the CO formula

Code: closed orbit formula

```

J = {{a1, b1}, {-1 + a1^2 / b1, -a1}};

MCO = FullSimplify[Inverse[IdentityMatrix[2] - (IdentityMatrix[2] Cos[2 π Q] + J Sin[2 π Q])]]

{{1/2 (1 + a1 Cot[π Q]), 1/2 b1 Cot[π Q]}, {-1 + a1^2 / b1 Cot[π Q], 1/2 (1 - a1 Cot[π Q])}}

x0 = FullSimplify[MCO.{0}, {01}]

{{1/2 b1 01 Cot[π Q]}, {1/2 (01 - a1 01 Cot[π Q])}}

Transport = {{sqrt[b2] (Cos[φ] + a1 Sin[φ]) / sqrt[b1], sqrt[b1] sqrt[b2] Sin[φ]}, {-(-a1 + a2) Cos[φ] + Sin[φ] + a1 a2 Sin[φ] / sqrt[b1] sqrt[b2], sqrt[b1] (Cos[φ] - a2 Sin[φ]) / sqrt[b2]}};

FullSimplify[Transport.x0]

{{1/2 sqrt[b1] sqrt[b2] 01 (Cos[φ] Cot[π Q] + Sin[φ])}, {-sqrt[b1] 01 (Cos[φ] (-1 + a2 Cot[π Q]) + (a2 + Cot[π Q]) Sin[φ]) / (2 sqrt[b2])}}

TrigReduce[Cos[φ] Cot[π Q] + Sin[φ]]

Cos[π Q - φ] Csc[π Q]

```

We found back the known equation

$$x_{CO}(s) = \frac{\sqrt{\beta(s)\beta(s_0)}}{2 \sin(\pi Q)} \theta_{s_0} \cos(\phi - \pi Q) \quad (8)$$

where ϕ is the phase advance (> 0) from s_0 to s .

Computing dispersion and chromaticity I

Up to now we considered all the optics parameters for the on-momentum particle. To evaluate the off-momentum effect of the closed orbit and the tune we introduce the dispersion, $D_{x,y}(s, \frac{\Delta p}{p_0})$, and chromaticity, $\xi_{x,y}(\frac{\Delta p}{p_0})$, respectively, as

$$\Delta CO_{x,y}(s) = D_{x,y}\left(s, \frac{\Delta p}{p_0}\right) \times \frac{\Delta p}{p_0}, \quad D_{x,y}(s + C) = D(s)$$

and

$$\Delta Q_{x,y} = \xi_{x,y}\left(\frac{\Delta p}{p_0}\right) \times \frac{\Delta p}{p_0}.$$

Computing dispersion and chromaticity II

In order to compute numerically the $D_{x,y}$ and $\xi_{x,y}$ one can compute first the $CO_{x,y}$ and the $Q_{x,y}$ as function of $\frac{\Delta p}{p_0}$.

To do that one has to compute $M_{OTM}(s, \frac{\Delta p}{p_0})$, that is evaluate the property of the element of the lattice as function of $\frac{\Delta p}{p_0}$.

- In a thin quadrupole the focal length linearly scales with the beam rigidity:

$$\begin{pmatrix} 1 & 0 \\ -\frac{1}{f(\frac{\Delta p}{p_0})} & 1 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 0 \\ -\frac{1}{f_0 \times (1 + \frac{\Delta p}{p_0})} & 1 \end{pmatrix}.$$

- A dipolar kick θ , scales with the inverse of the beam rigidity:

$$\begin{pmatrix} 0 \\ \theta(\frac{\Delta p}{p_0}) \end{pmatrix} \rightarrow \begin{pmatrix} 0 \\ \frac{\theta_0}{1 + \frac{\Delta p}{p_0}} \end{pmatrix}.$$

Where do we stand?

We learnt how to compute

- the invariant of the motions J_{CS} and J_H ,
- the betatronic phase, $\mu(s)$, along the lattice,
- the CO given a set of kicks,
- the dispersion and chromaticity.

We will consider in the following an ensemble of **non-interacting** particle and we will introduce the concept of beam emittance and beam matching.

The Beam distribution, a set of N particles

Figure 5: From single particle to particle ensembles.

The Beam distribution, a set of N particles I

To track N particles is possible by using the same approach of the single particle tracking were X becomes X_{Beam} , a $2n \times N$ matrix:

$$X_{Beam} = (X_1, X_2, \dots, X_n)$$

We will restrict ourself to the 1D case ($n=1$).

We are looking for one or more statistical quantities that represents this ensemble and its evolution in the lattice.

A natural one is the **average** J_H over the ensemble:

$$\frac{1}{N} \sum_{i=1}^N J_{H,i} = \langle J_H \rangle$$

From the definition it follows that the quantity is preserved during the beam evolution along the lattice.

Beam emittance

One can see that $\langle J_H \rangle$ converges, under specific assumptions (matched beam), to the **rms emittance** of the beam, ϵ_{rms}

$$\epsilon_{rms} = \sqrt{\det\left(\underbrace{\frac{1}{N} X_B X_B^T}_{\sigma \text{ matrix}}\right)}.$$

One can see that the ϵ_{rms} is preserved for the symplectic linear transformation M from s_0 to s_1 (see Cauchy-Binet theorem):

$$\begin{aligned}\epsilon_{rms}^2(s_0) &= \det\left(\frac{1}{N} X_B X_B^T\right) \\ \epsilon_{rms}^2(s_1) &= \det\left(M \underbrace{\frac{1}{N} X_B X_B^T}_{\sigma(s_0)} M^T\right) = \underbrace{\det M}_{=1} \det\left(\frac{1}{N} X_B X_B^T\right) \underbrace{\det M^T}_{=1}\end{aligned}$$

where X_B denotes $X_B(s_0)$. Note that $\sigma(s_1) = M \sigma(s_0) M^T$.

The σ matrix

By its definition we have (e.g., 1D trace-space) that

$$\sigma = \begin{pmatrix} \frac{1}{N} \sum_{i=1}^N x_i x_i & \frac{1}{N} \sum_{i=1}^N x_i x'_i \\ \frac{1}{N} \sum_{i=1}^N x'_i x_i & \frac{1}{N} \sum_{i=1}^N x'_i x'_i \end{pmatrix} = \begin{pmatrix} \overbrace{\langle \bar{x}^2 \rangle}^{x_{rms}^2} & \langle x x' \rangle \\ \langle x x' \rangle & \underbrace{\langle \bar{x}'^2 \rangle}_{x_{rms}'^2} \end{pmatrix}$$

and therefore we can write

$$\epsilon_{rms} = \sqrt{\langle x^2 \rangle \langle x'^2 \rangle - \langle x x' \rangle^2}.$$

So we show how to numerically transport the second-order moments of the beam distribution.

Matched beam distribution I

A beam distribution is matched to the specific optics functions $\bar{\alpha}$ and $\bar{\beta}$ if the corresponding normalized distribution is statistically invariant by rotation in the normalized space. In other words it has an azimuthal symmetry.

It is worth noting that since \bar{P}^{-1} is a symplectic matrix and defining $\bar{X}_B = \bar{P}^{-1} X_B$ we have that $\bar{\epsilon}_{rms} = \epsilon_{rms}$ and for a matched beam we have

$$\bar{\sigma} = \frac{1}{N} \bar{X}_B \bar{X}_B^T = \bar{P}^{-1} \sigma \bar{P} = \begin{pmatrix} \overbrace{\langle \bar{x}^2 \rangle}^{\bar{x}_{rms}^2} & \langle \bar{x} \bar{x}' \rangle \\ \langle \bar{x} \bar{x}' \rangle & \underbrace{\langle \bar{x}'^2 \rangle}_{\bar{x}_{rms}'^2} \end{pmatrix} = \begin{pmatrix} \epsilon_{rms} & 0 \\ 0 & \epsilon_{rms} \end{pmatrix}.$$

Therefore $\bar{\sigma}$ is diagonal.

Matched beam distribution II

Figure 6: A **matched** beam distribution in normalized trace-space.

Matched beam distribution III

Figure 7: A **mismatched** beam distribution in normalized trace-space.

Matched beam distribution IV

For a beam distribution matched to the specific optics functions $\bar{\alpha}$ and $\bar{\beta}$ the we have

$$\sigma = \bar{P} \bar{\sigma} \bar{P}^{-1} = \begin{pmatrix} \bar{\beta} \epsilon_{rms} & -\bar{\alpha} \epsilon_{rms} \\ -\bar{\alpha} \epsilon_{rms} & \bar{\gamma} \epsilon_{rms} \end{pmatrix} \quad (9)$$

where we found back the rms beam size and divergence formulas, $\sqrt{\bar{\beta} \epsilon_{rms}}$ and $\sqrt{\bar{\gamma} \epsilon_{rms}}$, respectively.

The rms size of a matched beam in a periodic stable lattice and at given position s_0 is a turn-by-turn invariant.

J_H and ϵ_{rms}

Before concluding this chapter we demonstrate that, for matched beam, we have $\langle J_H \rangle = \epsilon_{rms}$. In fact

$$J_H = \frac{\bar{x}^2 + \bar{x}'^2}{2}, \quad (10)$$

and, since the beam is matched then $\langle \bar{x}^2 \rangle = \langle \bar{x}'^2 \rangle = \epsilon_{rms}$, it yields

$$\boxed{\langle J_H \rangle = \left\langle \frac{\bar{x}^2 + \bar{x}'^2}{2} \right\rangle = \frac{\langle \bar{x}^2 \rangle + \langle \bar{x}'^2 \rangle}{2} = \epsilon_{rms}}. \quad (11)$$

About ensembles

- We extended the single particle computation method to transport ensembles of particles.
- We introduced the concepts of beam σ matrix, the ϵ_{rms} , its relation with the $\langle J_H \rangle$ and the concept of beam matching.

MAD-X in 20 min...

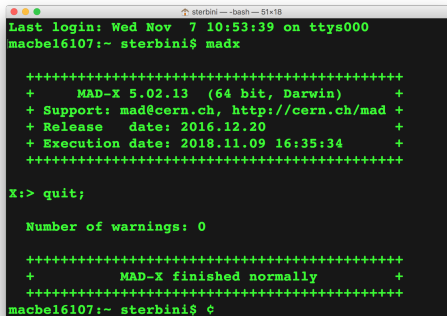

DISCLAIMER

- This material is intended to be an short introduction to MAD-X: a large part of the code capabilities are not discussed in details or are not discussed at all!
- Please refer to MAD-X web site <http://madx.web.cern.ch/> to learn more.

What is MAD-X?

Methodical Accelerator Design version X

- A general purpose (free) beam optics and lattice program.
- It is used since more than 30 years.
- MAD-X is written in C/C++/Fortran77/Fortran90 (source code is available under CERN copyright).

A terminal window titled 'sterbini -- bash -- 51x18' showing the execution of the 'madx' command. The output displays version information, support contact, release date, and execution date, followed by a confirmation that MAD-X finished normally.

```
sterbini -- bash -- 51x18

A general purpose beam optics code

For circular machines, beam lines and linacs...

- Describe/document parameters from machine description.
- Design a lattice for getting the desired properties (matching).
- Simulate beam dynamics, imperfections and operation.

A general purpose beam optics code

MAD-X is

- **multiplatforms** (Linux/OSX/WIN...),
- very **flexible** and easy to extend,
- made for complicated applications, **powerful** and rather complete,
- mainly designed **for large projects** (LHC, CLIC, FCC...).

In large projects (e.g., LHC):

- Must be able to handle machines with $\geq 10^4$ elements,
- many simultaneous MAD-X users (LHC: more than 400 around the world): need consistent database,
- if you have many machines: ideally use only one design program.

Describe an accelerator in MAD-X

Goals...

- **Describe, optimize and simulate** a machine with several thousand elements eventually with magnetic elements shared by different beams, like in colliders.

MAD-X language

How does MAD-X get this info? Via text (**interpreter**).

- It accepts and executes statements, expressions. . . ,
- it can be used interactively (**input from command line**) or in batch (**input from file**),
- many features of a programming language (loops, if's, . . .).

All input statements are analysed by a parser and checked.

- E.g. **assignments**: properties of machine elements, set up of the lattice, definition of beam properties, errors. . .
- E.g. **actions**: compute lattice functions, optimize and correct the machine. . .

MAD-X input language

- Strong resemblance to "C" language (but NO need for declarations and NOT case sensitive apart in expressions in inverted commas),
- free format, all statements are terminated with ; (do not forget!),
- comment lines start with: // or ! or is between /*...*/ ,
- Arithmetic expressions, including basic functions (**exp**, **log**, **sin**, **cosh**...), built-in random number generators and predefined constants (speed of the light, e , π , m_p , m_e ...).

In particular it is possible to use deferred assignments

- regular assignment: **a = b**, if **b** changes **a** does not,
- deferred assignment: **a := b**, if **b** changes **a** is updated too.

EXAMPLE: deferred assignments

```
sterbini --bash -- 54x19
+++++
+      MAD-X 5.02.13  (64 bit, Darwin)      +
+ Support: mad@cern.ch, http://cern.ch/mad +
+ Release  date: 2016.12.20                +
+ Execution date: 2018.11.10 10:16:13      +
+++++

X:> a=1;
X:> b=a;
X:> c:=a;
X:> a=2;
+++++ info: a redefined
X:> value a;
a              =              2 ;
X:> value b;
b              =              1 ;
X:> value c;
c              =              2 ;
X:> quit;
```

We use the **value** command to print the variables content.

Definitions of the lattice elements

Generic pattern to define an element:

label: *keyword*, *properties*...;

- For a dipole magnet:
MBL: **SBEND**, **L**=10.0;
- For a quadrupole magnet:
MQ: **QUADRUPOLE**, **L**=3.3;
- For a sextupole magnet:
MSF: **SEXTUPOLE**, **L**=1.0;

In the previous examples we considered only the **L** property, that is the length in meters of the element.

The **strength** of the elements

The name of the parameter that define the **normalized magnetic strength** of the element depends on the element type.

- For dipole (horizontal bending) magnet is k_0 :

$$k_0 = \frac{1}{B\rho} B_y \text{ [in m}^{-1}\text{]}$$

- For quadrupole magnet is k_1 :

$$k_1 = \frac{1}{B\rho} \frac{\partial B_y}{\partial x} \text{ [in m}^{-2}\text{]}$$

- For sextupole magnet is k_2 :

$$k_2 = \frac{1}{B\rho} \frac{\partial^2 B_y}{\partial x^2} \text{ [in m}^{-3}\text{]}$$

Interlude

What does k_1 mean? It is related to the quad focal length ².

$$\frac{1}{k_1 L_{quad}} = f \quad (12)$$

Assuming $k_1 = 10^{-1} \text{ m}^{-2}$ and $L_{quad} = 10^{-1} \text{ m}$ the $f = 10^2 \text{ m}$.

²thin lens approximation

EXAMPLE: definitions of elements

- Kicker magnet:

theta = 1e-6;

KICK: HKICKER, L=0, HKICK=theta;

- Multipole magnet "thin" element:

MMQ: MULTIPOLE, KNL = { $k_0 \cdot l$, $k_1 \cdot l$, $k_2 \cdot l$, $k_3 \cdot l$, ... };

- LHC dipole magnet as thick element:

length = 14.3;

p = 7000;

angleLHC = 8.33 * clight * length/p;

MBL: SBEND, ANGLE = angleLHC;

The lattice sequence

A lattice sequence is an ordered collection of machine elements.

Each element has a position in the sequence that can be defined wrt the CENTRE, EXIT or ENTRY of the element and wrt the sequence start or the position of an other element:

```
label: SEQUENCE, REFER=CENTRE, L=length;
```

```
...;
```

```
...;
```

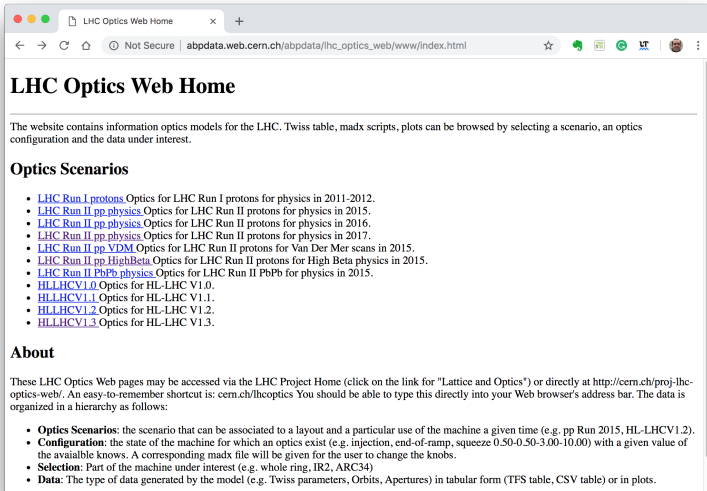

```
... here specify position of all elements. ...;
```

```
...;
```

```
...;
```

```
ENDSEQUENCE;
```

EXAMPLE: www.cern.ch/lhcoptics

The screenshot shows a web browser window with the address bar displaying `abpdata.web.cern.ch/abpdata/lhc_optics_web/www/index.html`. The page title is "LHC Optics Web Home". The main content area has a heading "LHC Optics Web Home" followed by a paragraph: "The website contains information optics models for the LHC. Twiss table, madx scripts, plots can be browsed by selecting a scenario, an optics configuration and the data under interest." Below this is a section titled "Optics Scenarios" with a bulleted list of links and descriptions. At the bottom is an "About" section with a paragraph and a bulleted list of definitions.

LHC Optics Web Home

The website contains information optics models for the LHC. Twiss table, madx scripts, plots can be browsed by selecting a scenario, an optics configuration and the data under interest.

Optics Scenarios

About

These LHC Optics Web pages may be accessed via the LHC Project Home (click on the link for "Lattice and Optics") or directly at <http://cern.ch/proj-lhc-optics-web/>. An easy-to-remember shortcut is: cern.ch/lhcoptics You should be able to type this directly into your Web browser's address bar. The data is organized in a hierarchy as follows:

- **Optics Scenarios:** the scenario that can be associated to a layout and a particular use of the machine a given time (e.g. pp Run 2015, HL-LHCv1.2).
- **Configuration:** the state of the machine for which an optics exist (e.g. injection, end-of-ramp, squeeze 0.50-0.50-3.00-10.00) with a given value of the available knobs. A corresponding madx file will be given for the user to change the knobs.
- **Selection:** Part of the machine under interest (e.g. whole ring, IR2, ARC34)
- **Data:** The type of data generated by the model (e.g. Twiss parameters, Orbits, Apertures) in tabular form (TFS table, CSV table) or in plots.

EXAMPLE: the LHC sequence

```

Beam definition & sequence activation

Generic pattern to define the beam:

label: **BEAM**, **PARTICLE**=x, **ENERGY**^a=y,...;

e.g., **BEAM**, **PARTICLE**=proton, **ENERGY**=7000; //in GeV

^aIt is the TOTAL energy!

After a sequence has been read, it can be activated:

USE, **SEQUENCE**=sequence_label;

e.g., **USE**, **SEQUENCE**=lhcl;

The **USE** command expands the specified sequence, inserts the drift spaces and makes it active.

Definition of operations

Once the sequence is activated we can perform operations on it.

- Calculation of Twiss parameters around the machine (**very important**) in order to know, for stable sequences, their main optical parameters.

```
TWISS, SEQUENCE=sequence_label; //periodic solution
```

```
TWISS, SEQUENCE=sequence_label, betx=1; //IC solution
```

- Production of graphical output of the main optical function (e.g., β -functions):

```
PLOT, HAXIS=s, VAXIS=betx,bety;
```

Example

```
TWISS, SEQUENCE=juaseq, FILE=twiss.out;
```

```
PLOT, HAXIS=s, VAXIS=betx, bety, COLOUR=100;
```

EXAMPLE of a the TWISS file

```

....
....
```

EXAMPLE of the graphical output (ps format)

Matching global parameters

It is possible to modify the optical parameters of the machine using the MATCHING module of MAD-X.

- Adjust magnetic strengths to get desired properties (e.g., tune Q, chromaticity dQ),
- Define the **properties** to match and the **parameters** to vary.

Example:

```
MATCH, SEQUENCE=sequence_name;  
  GLOBAL, Q1=26.58;//H-tune  
  GLOBAL, Q2=26.62;//V-tune  
  VARY, NAME= kqf, STEP=0.00001;  
  VARY, NAME = kqd, STEP=0.00001;  
  LMDIF, CALLS=50, TOLERANCE=1e-6;//method adopted  
ENDMATCH;
```

Other types of matching I

Local matching and performance matching:

- Local optical functions (insertions, local optics change),
- any user defined variable.

Other types of matching II

Local matching and performance matching:

- Local optical functions (insertions, local optics change),
- any user defined variable.

Example:

```
MATCH, SEQUENCE=sequence_name;  
  CONSTRAINT, range=#e, BETX=50;  
  CONSTRAINT, range=#e, ALFX=-2;  
  VARY, NAME= kqf, STEP=0.00001;  
  VARY, NAME = kqd, STEP=0.00001;  
  JACOBIAN, CALLS=50, TOLERANCE=1e-6;  
ENDMATCH;
```
