Material from various papers and books (bibliography at the end)

- Trigger and DAQ system concepts
- From signal to physics through examples
- Timing
- Data transport, links, buses
- Queues and Event building
- On-line data processing

- We have our ADC/TDC counts, but how do we correlate them with energy/position ?
- Need a calibration procedure

Calibration

- The experiments we discussed provide relative measurements. The values obtained via our system are in some (known) relation with the interesting quantity

- Scintillator

$$Q \propto N_\gamma \propto E$$

- XDWC

$$y = \alpha \cdot \Delta t + \beta = \alpha \cdot (t_{top} - t_{bottom}) + \beta$$

- Our instruments need to be in order to give us the answer we are looking for
 - We have to determine the **calibrated** parameters that transform the raw data into a physics quantity
 - The parameters normally depend on the experimental setup (e.g. cable length, delay settings, HV settings, ...)
- In the design of our detector and DAQ we have to foresee calibration mechanisms/procedures

Ge crystal for isotope identification

Crystal HPGe

Readout (ADC)

Trigger & front-end

Crystal calibration

- ^{152}Eu reference source
 - Known emission lines
 - Peak find & fit
- Allow for definition of the parameters describing functional relation between ADC count and E

$$Q \propto N_\gamma \propto E$$

- Reality is not perfectly linear
 - Polynomial fits
 - Physical models

Isotope identification

Calibrated crystal setup can be used to identify isotopes generated in irradiated samples

XDWC Calibration

- XDWC chamber have 3 calibration inputs that allow for independent calibrations of X and Y axis with only 3 different sets of data
- The calibration input simulate signals from particles respectively hitting
 - Right-top corner (X=Y=30mm)
 - Center (X=Y=0mm)
 - Left-bottom corner (X=Y=-30mm)
- The calibration data sets are collected with final setup and TDC
- Interpolating the three points in the t - x space, the parameters of the calibration equation can be measured

$$x = at^* + \beta$$

Calibration: summary

- Our DAQ chain provides us with numbers (raw data) but ... what do they really mean ?
- Likely related with physics quantities but with relations (transfer functions) affected by several uncertainties:
- due to physical detection mechanisms
- due to signal processing
- Transfer functions usually parameterised, sometimes based on (look-up) numeric tables
- All system elements need to be calibrated to keep optimal knowledge of all parameters:
 - calibration procedures
 - calibration constants
- Calibration constants change with ageing (mainly due to radiation), beam conditions (electronics may have baseline drifting with pile-up), time ... HV, LV, ...
- The design of our detector and DAQ has to foresee calibration mechanisms/procedures
- injection of known signals
- dedicated calibration *triggers* and data streams

Atlas tile calorimeter calibration system

Laser System

Detector non-uniformities
Cesium System

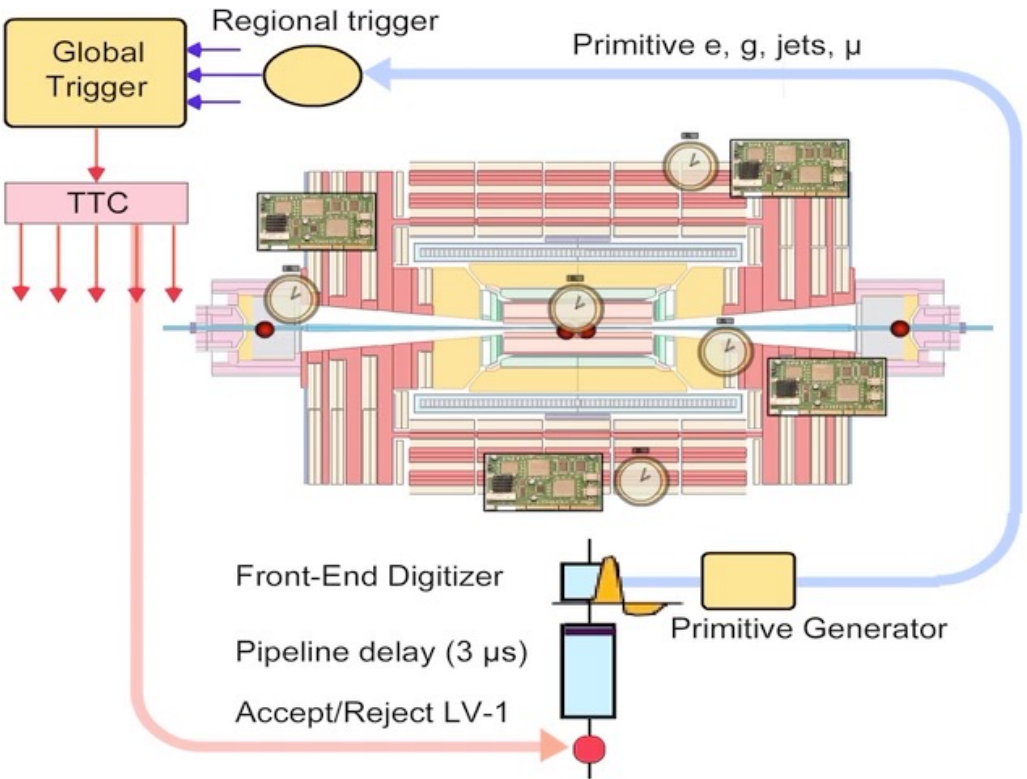

ADC count to charge
Charge Injection System

$$E_{channel} = A \cdot C_{ADC \rightarrow pC} \cdot C_{pC \rightarrow GeV} \cdot C_{Cs} \cdot C_{laser}$$

Time

Time

Clock distribution

- Let's assume that your clock is received from an external source in “perfect” shape
 - For example the accelerator RF system
 - Or a time base for absolute time
- In order to have synchronized clocks in the detector, the signal has to be copied many times and distributed over thousands of connections
 - It is affected by
 - Length and quality of the transmission line
 - Environmental factors (temperature, humidity...)
 - It traverses a lot of intermediate electronics
 - In an environment full of noise sources
 - EM fields
 - Other electronics
 - Power supplies
 - ...
- Distributing an accurate clock is far from trivial

Noiseless binary information signal:

Above signal after transmission through a bandlimited system:

Superposition of noise:

Reshaped signal:

Fig. 2.2-33

Consequences of jitter

- The time references may be accurate in absolute terms but may have **phase differences at different places** in the detector
- The time reference may **not be stable and exhibit slow or fast phase variation**
- The jitter may affect your digitized data in different ways
 - **Distortion** of the digitized pulse
 - **Errors** in time measurement of a TDC
- On a trigger system the effect can be dramatic:
 - A trigger signal is **issued for the wrong time bucket** (corresponding to bunch-crossing or a specific instant in time)
 - As a result, the wrong information is stored (you take the picture too early, or too late)
- Mismeasurement due to jitter can also have serious effects
 - For example you can mis-measure a time of flight and take some wrong conclusion

Example: Augier

- Detect air showers generated by cosmic rays above 10^{17} eV
- Expected rate $< 1/\text{km}^2/\text{century}$. Two large area detectors
- On each detector, a 3-level trigger operates at a wide range of primary energies, for both vertical and very inclined showers

L1: (local) decides the pixel status (on/off)

- ADC counts $>$ **threshold**
- ADC digitizes any 100 ns (**time resolution**)
- ADC values stored for 100 μ s in **buffers**
- **Synchronized** with a signal from a GPS clock

L2: (local) identifies track segments

- Geometrical criteria with recognition algorithms on programmable patterns

L3: (central) makes spatial and temporal correlation between L2 triggers

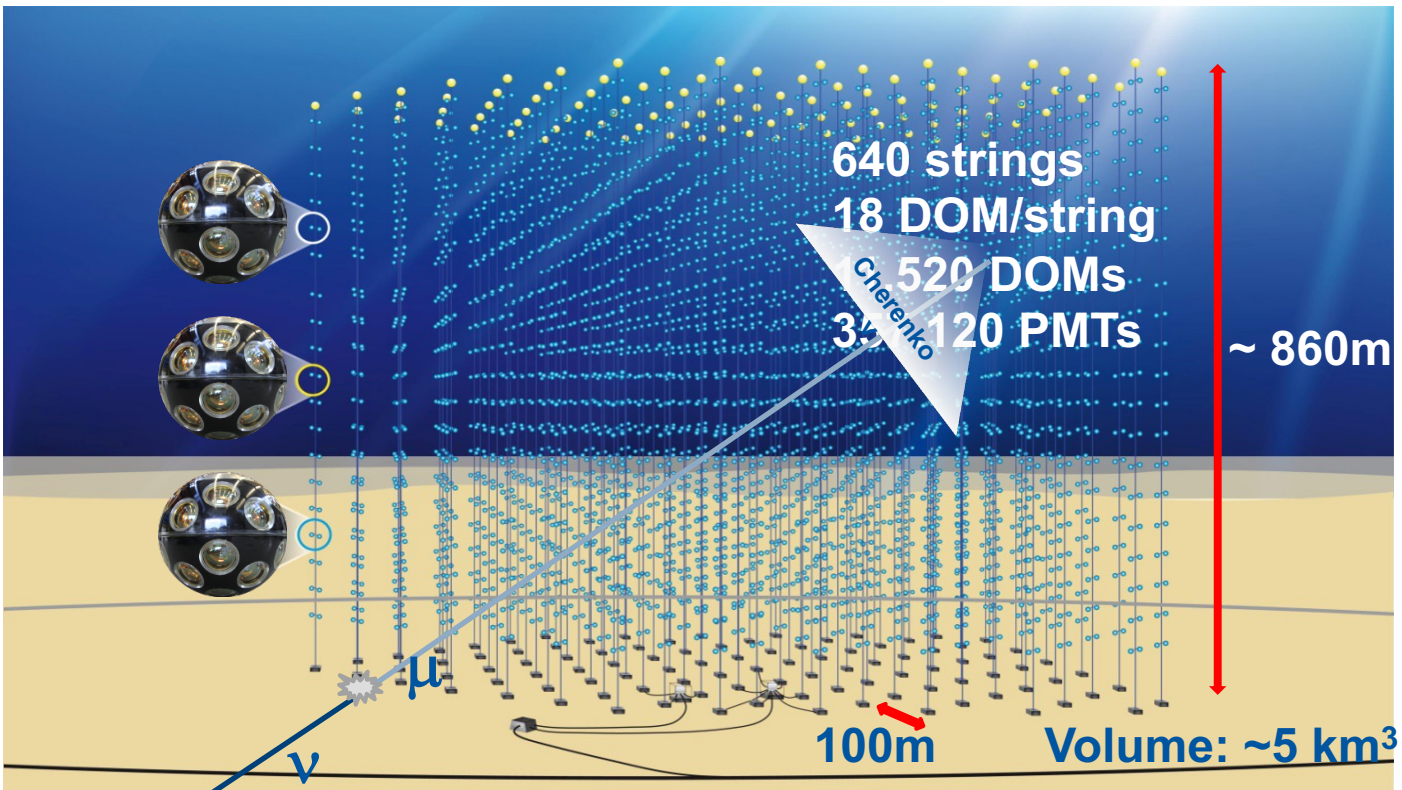

One event \sim 1MB \rightarrow 0.2 MB/s bandwidth needed for the DAQ system

Where it's important ?

Timestamping

Syntonization

- Distribute frequency

- Average clock edges
- Added single shot channel jitter

- Distributing frequency = Syntonization:
 - “The adjustment of two electronic circuits or devices in terms of frequency”

A timing system should distribute

- clock
 - with appropriate phase relative to some reference (e.g. the LHC bunch structure)

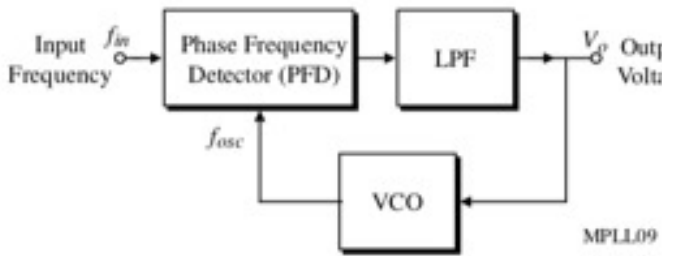

- L1-trigger (can be complex information)
- Bunch Counter (increment on LHC clock)
- Event Counter (increment on L1A)
- Additional synchronization commands for the front-end
- **Must be radiation and field tolerant (for colliders)**

One system

- Ideally, you want to distribute the clock AND the remaining information with a single system
- The clock could be embedded in a high-speed serial stream: can it be recovered with sufficient stability ?
 - What is “sufficient” ?

Phase-locked loop

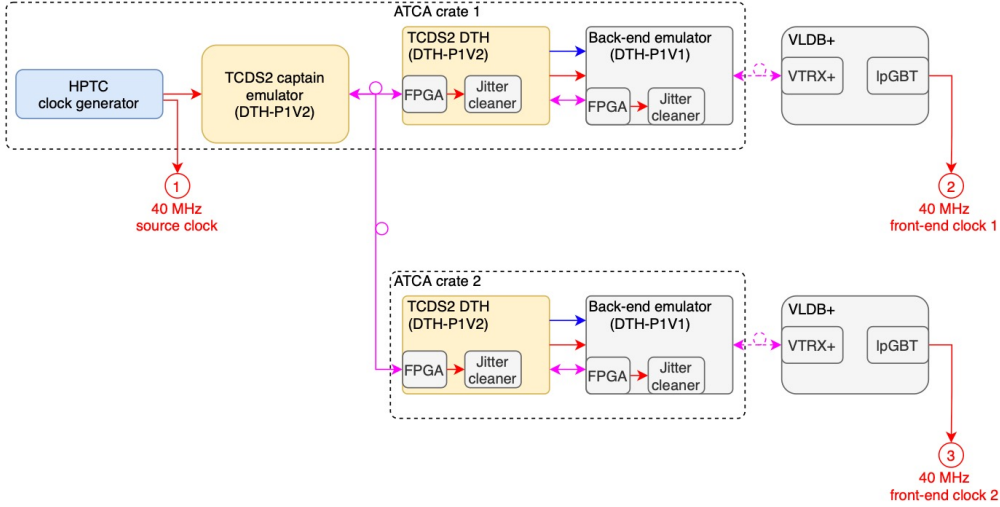

- recover a noisy signal (jitter cleaning)
- generate a stable frequency at multiples of an input frequency (clock synthesis)
- distribute precisely timed clock pulses (clock distribution)

Problem: limited range of frequency
If input drifts -> unlock

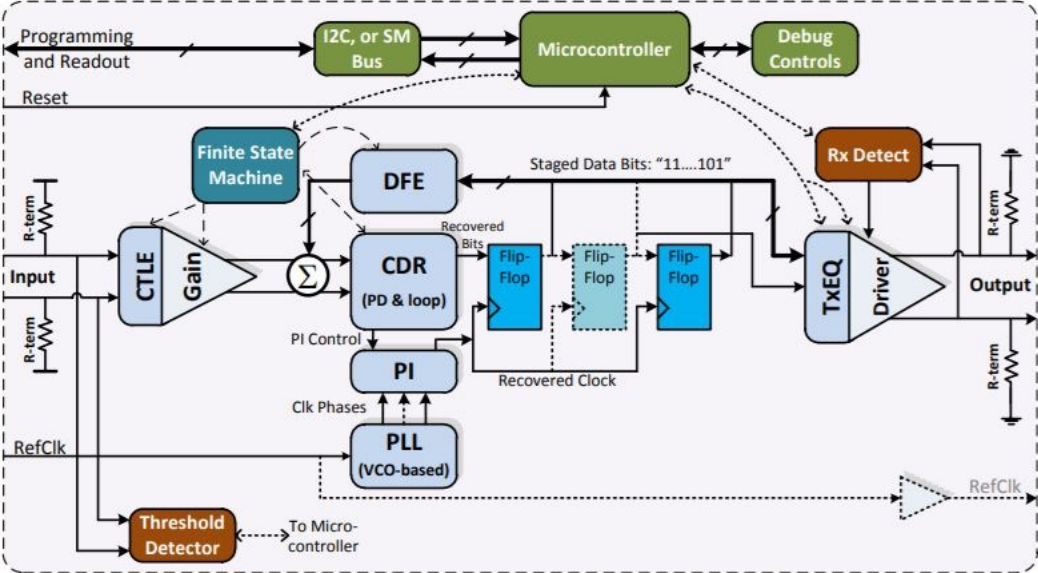

Delay-lock loop:
VCO replaced by programmable delay line

Measuring phase noise

RMS jitter is obtained by integrating the phase noise power spectrum over the entire frequency band

More complex tools

<https://pcisig.com/pci-express®-retimers-vs-redrivers-eye-popping-difference>

What are the applications that demand most phase stability ?

What is pileup

Top pair event + 140 additional low energy interactions
"Classical" spatial view of the vertices

Identifying vertex by time of flight

- With two time and position measurements eg. from two photons and with the constraint from the beam axis x and y location, the vertex x and t can be calculated.
- Equivalent to GPS with two satellites.

WolframAlpha computational knowledge engine

solve $a = \sqrt{b + (d-z)^2} - \sqrt{c + (e-z)^2}$ for z

Input interpretation:
 solve $a = \sqrt{b + (d-z)^2} - \sqrt{c + (e-z)^2}$ for z

Results:

$$z = \frac{(a^2 d + a^2 e - \sqrt{(a^6 - 2a^4 b - 2a^4 c - 2a^4 d^2 + 4a^4 d e - 2a^4 e^2 + a^2 b^2 - 2a^2 b c + 2a^2 b d^2 - 4a^2 b d e + 2a^2 b e^2 + a^2 c^2 + 2a^2 c d^2 - 4a^2 c d e + 2a^2 c e^2 + a^2 d^4 - 4a^2 d^3 e + 6a^2 d^2 e^2 - 4a^2 d e^3 + a^2 e^4) - b d + b e + c d - c e - d^3 + d^2 e + d e^2 - e^3)}{2(a^2 - d^2 + 2d e - e^2)}$$

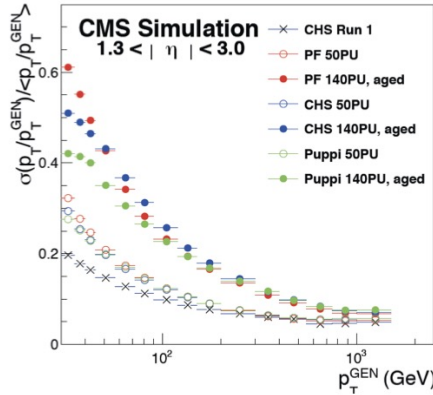

$$z = \frac{(a^2 d + a^2 e + \sqrt{(a^6 - 2a^4 b - 2a^4 c - 2a^4 d^2 + 4a^4 d e - 2a^4 e^2 + a^2 b^2 - 2a^2 b c + 2a^2 b d^2 - 4a^2 b d e + 2a^2 b e^2 + a^2 c^2 + 2a^2 c d^2 - 4a^2 c d e + 2a^2 c e^2 + a^2 d^4 - 4a^2 d^3 e + 6a^2 d^2 e^2 - 4a^2 d e^3 + a^2 e^4) - b d + b e + c d - c e - d^3 + d^2 e + d e^2 - e^3)}{2(a^2 - d^2 + 2d e - e^2)}$$

Computed by Wolfram|Mathematica

Pileup mitigation with timing detector

- High pile-up has major impact on JetMET reconstruction.
- At low p_T (40 GeV) PU energy in the jet cone exceeds the jet energy by a factor 2 or more.
- Each PU event adds 3 GeV in quadrature to the MET resolution, resulting in about 40 GeV for 200 GeV.

Correct vertex identification

- **Synergies between Calorimetric and MIP timing : Increased efficiency for time vertexing.**
- **$H \rightarrow \gamma\gamma$ use case : Vertex ID efficiency 80% in Run I, 40% expected in HL-LHC, 55% with photon-only time vertex, 75% with photon+track time vertex.**
- **Results corresponds to a 10% and 30% increase in equivalent luminosity.**
- **Results to be presented at the [ECFA workshop](#) in Aix les Bains.**

Requirements

The reference clock must have phase accuracy better than the target resolution

- Target time resolution of 30 ps achieved
 - Noise jitter term <25 ps for gain>15
 - $\sim N/(dV/dt)$
 - Intrinsic limit from Landau fluctuations:
 - Spatially non-uniform energy deposits along the track cause event-by-event pulse distortions
 - Constant: ~ 25 ps

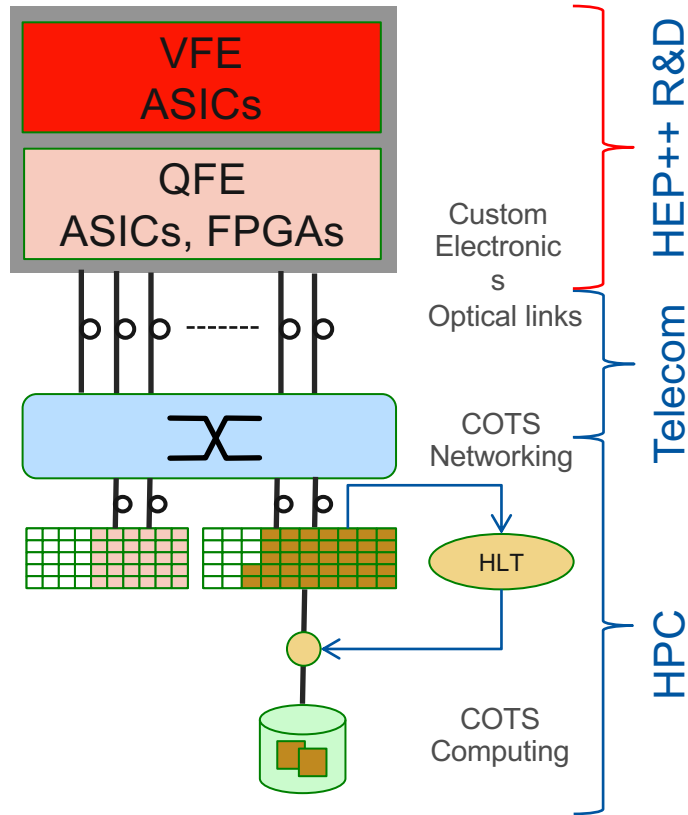

Design of the CMS Mip Timing Detector (MTD)

Wrap-up

Visionary part

DAQ: nice and easy

VFE does the analog part, ADC, low-level calibration, zero suppression, lossless compression, *optical links*

low-power, rad-hard (*rad-tolerant*)

QFE does medium scale aggregation, local reconstruction, "lossy" compression, transition to standard protocol on optical links

asynchronous – precision clock - timestamping

COTS switched networks provide further aggregation, up to and including event building

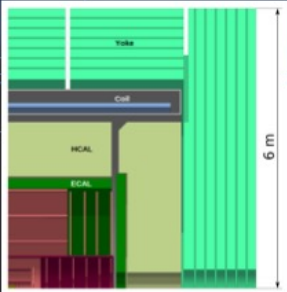

COTS servers with co-processors do the final selection

One-size-fits-all type of problem

Some real-life problems

11

3.7 ns interbunch at Z pole
 Rates are high but events small
Tracker with many channels but occupancy low (~kB??)
Trigger not challenging, but precision measurements benefit from multiple strategies
Trigger-less data rates similar to HL-LHC
 Stepping stone for the hh detectors

Beyond HL-LHC

- Higher energy
 - larger B field, solenoid bore radius -> tracker
- 400 m² silicon, 10¹⁰ channels
- Higher to extreme fluences, less accessibility
- Luminosity: always as high as possible
 - Shorter interbunch to reduce PU ?

Comparison to ATLAS & CMS

distance links
Reliability

Common needs for reliable systems

Shafts:

- Experimental Shafts: 15 m dia. + 10 m dia.
- Service shafts: 12 m dia.
- Magnet delivery shaft: 18 m

Tunnels:

- 97.75 km of 5.5 dia. machine tunnel
- Approx. 8 km 5.5 dia by-pass tunnels

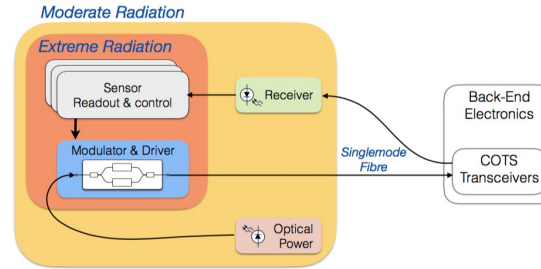

Optimistic outlook / lessons learned

- Move “as early as possible” to COTS networking
 - Requires buffer at sender (PC memory or something else)
 - Bare Ethernet not lossless unless sufficient buffer at switch (must keep usage below ~50%) - residual losses as deadtime (accounting) – need reliable delivery
- Could move “EVB” functionality to BE
 - Reliable protocol using HBM for congestion, aggregation
 - Integrated in back-end
 - Complete fw implementation of e.g. TCP
 - Delegate final EVB to HLT nodes (mild timestamping)
- **Economic and sociological reasons (may) make this hard**

More stuff (it time allows)

First stop: Readout at FE

- Optical Data Transmission technology is key
 - High Bandwidth **low mass, low power**
 - Immune to **electromagnetic interference** (+ isolation between power and readout)
 - Sufficiently **radiation tolerant**

- Optical layer is only part of the story
 - **Acquisition, aggregation, and serialisation before** transmission over the link
- **ASICs** need to be specified and designed to meet system requirements
 - Increasingly complex over generations
 - Common developments are key
 - Reuse (of design, concept)

synchronous or asynchronous

- Using COTS at FE == profit of high bandwidth “for free”
 - Fixed speed and narrow locking range
- Asynchronous readout (with time stamping...)
 - less complex back-end electronics
 - In principle can use “standard” protocol (e.g. Ethernet) and connect “quasi-FE” to “commercial” equipment
 - Challenging clock distribution, disciplined clock, phase stability at FE
 - Additional bandwidth
- Synchronous
 - RF stability (ramps) and distribution vs. locking range
 - COTS not compatible with specific RF frequencies
 - need deterministic behavior (and if not, can losses be afforded/quantified)
 - Deterministic protocols hard
 - Reliable protocols require lots of buffer at the sender (and are not deterministic by construction)

“trigger-less” is good ?

Trigger ::= read out everything (or “just without” L1 trigger) ?

- + Reduce relevance of custom processors and special data paths
- More **high speed links at or near the front end** (with the usual problems...)
 - material budget (for power, cooling, fibres)
 - rad hardness (of optical transmitters, fibres)
 - Will get worse at “future” colliders
 - Optical on FE needs a lot of technology for which we are the only customers
- Do aggregation and optical links **as close as possible to FE**
 - “Lossy” data reduction, it looks a bit like trigger ? – but, at FE, level of **aggregation is limited by**
 - **geometrical distribution of sources**
 - **space available**
 - **Environment to place connectivity / intelligence (the usual...rad,temp,field...)**
- Transition to COTS
 - Link speeds are constrained by COTS standards
 - Speaks in favor of abandoning synchronous readout

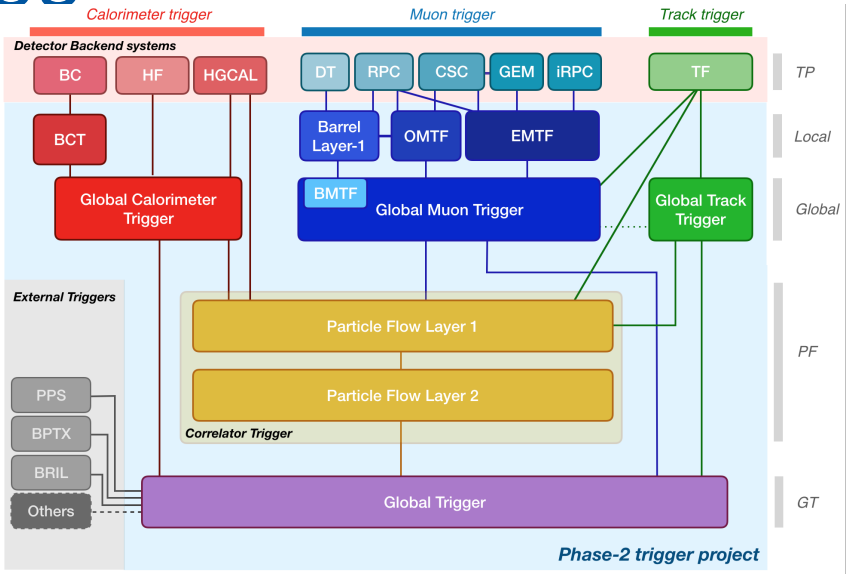

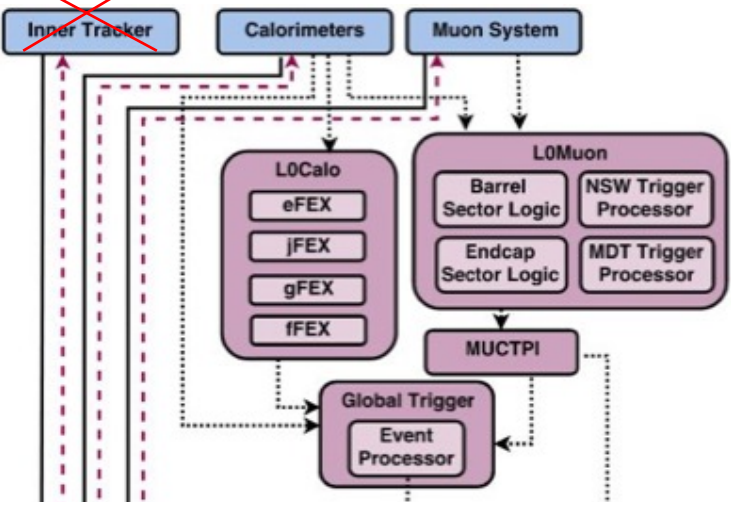

Caveat

- Turns out that “doing everything in software” is not so easy even with a HW L1 trigger
 - size of the switched network, amount of buffer to allow for “non-deterministic” behaviour of software algorithms
- amount of computing needed vs. CPU evolution
 - With asynchronous time-stamped data, just assembling the right pieces would not be a trivial task
 - Lots of low-hanging fruit ends up being a bit too high
 - GPUs...help but transition is slow (but at least it is happening)

- ...people end-up proposing FPGA custom co-processors...
- ...or pre-processors (anyone ?) [while there is general consensus now that ASICs are hard a lot of people still think that custom boards with FPGAs are easy]...beats the purpose ?
 - Paying for CPU is not popular...people will want to develop their own boards
 - That's how projects get funded at institutions: **not to develop software, or even firmware** (see later in “sociology”)

A look at the hardware triggers

Some draconian “**lossy compression**” here

- Get rid of entire detectors, make “trigger cells”, “trigger primitives”
- Final outcome is...well, one bit

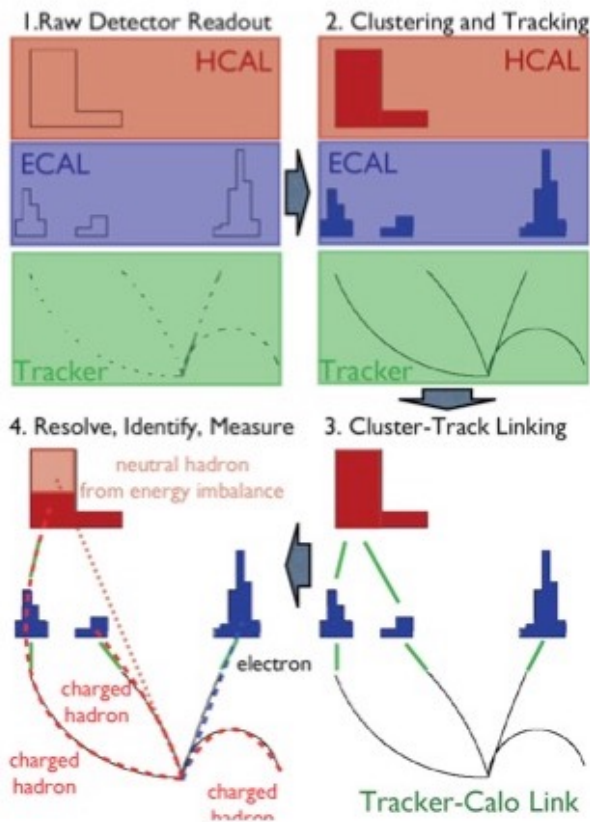

Some “trigger-less” readout

- Trigger inputs ARE **read out at BX rate** (in some cases “primitives” are made at back-end, from streaming data)
- Trigger processors do **aggregation**
 - In some cases information from **multiple sub-detectors** are combined

There is a lot of **information in the intermediate layers** of the hw trigger...perhaps something to be learned there

Yet one wants to do fancy things

- Several aspects to point out here:
- Enough information to “do the job”
 - Aggregate it in the correct dimension
 - Do all this within a short time
 - Modular systems with custom interconnects
 - Lots of complex algorithms to code in firmware

Some intelligence in the detector...

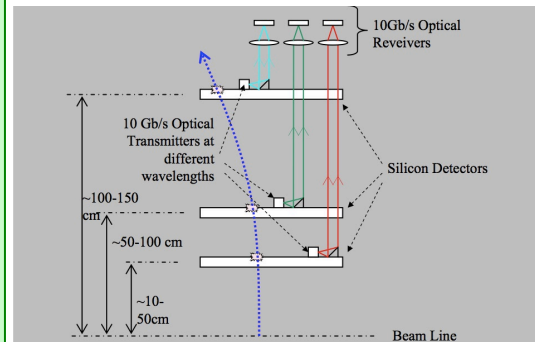

If one wants to do more Interconnects are needed

Inefficient at low P_t , large impact parameter, large η

Lossy compression requires sparsity in some space
VFE connectivity insufficient (or in the wrong dimension)

- Zero-th order problem: how to use complex, highly granular detectors in the trigger
- First order problem: how to make high-rate read-out possible (with or without trigger)
 - You can't get rid of complex front-end (and back-end) if you can't get rid of a hardware trigger
- Second order problem: build a tracker that spits out tracks, a calorimeter that spits out clusters ?

Some cursory conclusion

Hardware L1 is now a system of (generic) processors doing “local” event building, and processing events in parallel – **L1 and HLT are approaching**

- As an aside, this can and must be exploited to reduce the computation needs of the HLT
 - L1 objects much more useful
- Can capture L1 data for use in “physics at BX rate” (L1 “scouting”)

Both L1 and HLT only require “**trivial**” **parallelism**: work on one BX (event) at a time.

- Driven by the almost-synchronous nature of the task – could be challenged by **asynchronous readout** and/or **multi-bx phenomena** (VLL)
- Information **only flows in one direction** – sub-optimal use of bi-directional links (but easy traffic) [on-demand event building...]

Some cursory conclusion

A hardware trigger can live with (very) lossy compression because it just needs enough information to classify events and be “**mostly correct**” – that L1 is only mostly correct is an **accepted fact of life** (see below)

Whatever readout scheme one chooses **needs to be “almost always correct”** – at the lowest level possible (i.e. not miss a track or know exactly what you missed):

- Ability to **extract all relevant information** from front-end electronics
 - Readout scheme
 - Lossy compression and traffic equalization (ML techniques...CNN, AE (?), compressive sensing (??))
- Ability to **aggregate and process data at sufficient scale** “on-detector”
 - Interconnect at “quasi” front-end
 - Powerful FPGA-based processors that can work in QFE environment
 - Still a lot of downstream connectivity, if possible on COTS
- Accept a redefinition of what “raw-data” means (notice that such a redefinition is mostly NOT yet accepted at the next level, i.e. HLT)

Future DAQ/trigger system will
need **“holistic” system
engineering at detector design
level**

that takes into account readout
(and trigger if necessary)

Thank you
