Particle production and entropy measurement in ALICE

Wednesday, 6 September 2023 11:00 (20 minutes)

One of the main goals in the study of hadronic interactions at LHC energies is the attempt to characterize the mechanisms involved in particle production in different regimes. The charged-particle multiplicity is one of the most interesting observables in these kind of studies. On the one hand, the pseudorapidity dependence of charged-particle production provides information on the partonic structure of the colliding hadrons and is sensitive to non-linear QCD evolution in the initial state. Measurements of charged-particle pseudorapidity densities in pp collisions at \( \sqrt{s} = 13.6 \) TeV and in Pb-Pb collisions at \( \sqrt{s_{NN}} = 5.36 \) TeV will be presented, for the first time with the wider pseudorapidity coverage achieved by ALICE in Run 3 thanks to newly installed central and forward trackers. On the other hand to understand the thermal-like behavior and the particle yields in pp collisions, a possible approach is to address the principles of quantum states and their entanglement in the produced system. The entanglement in the initial state has a measurable effect on the evolution of the system and is the driving mechanism behind the thermal-like behavior and particle yields observed. We will show equivalence in a calculation of the initial state entropy (calculated using PDF’s) and the final state entropy (calculated using multiplicity distributions) studying primary charged particles produced in pp collisions at 13 TeV.
