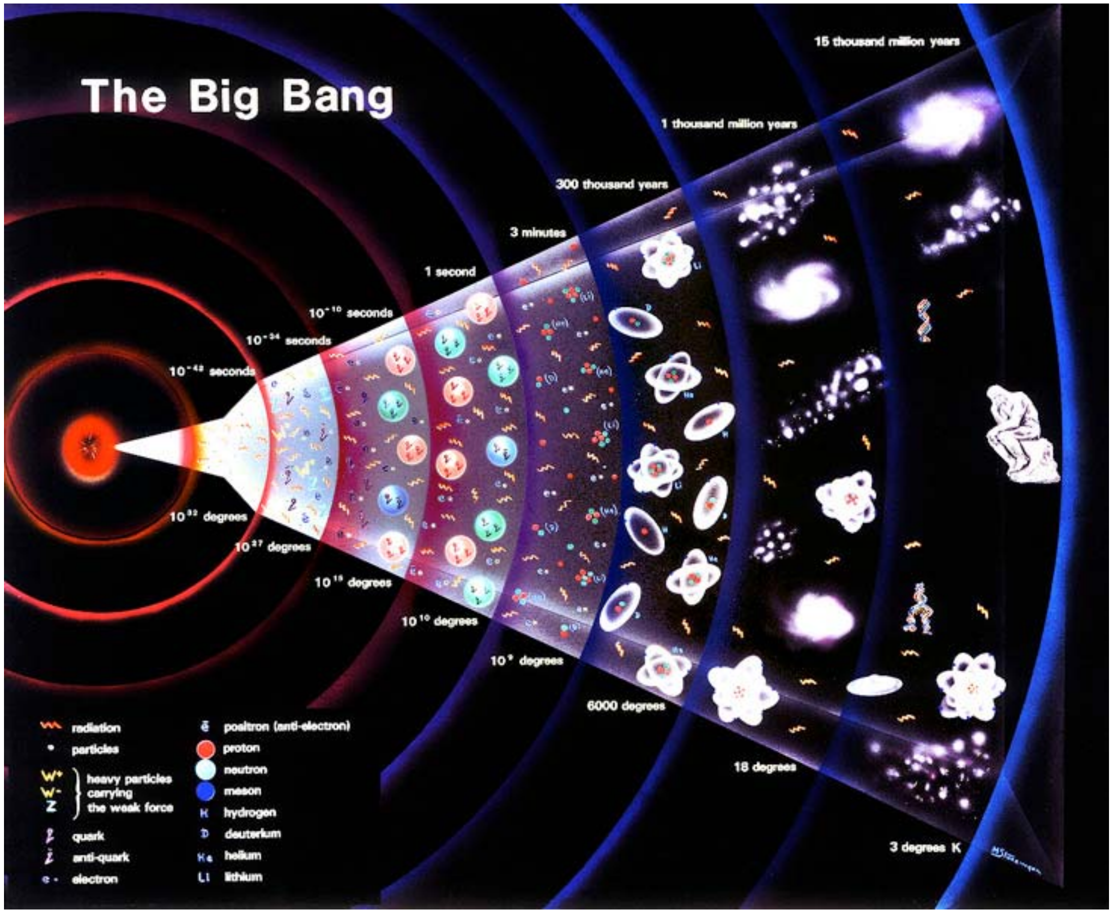
Precision Electroweak Physics at CDF

Ashutosh Kotwal
Duke University



Workshop on Precision LHC Physics
Paris, December 16, 2010

Precision Physics at CDF

- QCD and PDF-related measurements
  - P_T spectrum of Z bosons
  - Measurement of angular decay distribution coefficients in W and Z boson decays to leptons
  - Charge asymmetry in W boson production and decay
  - Z boson rapidity spectrum

- Measurements related to electroweak sector
  - Top quark mass measurement
  - W boson mass measurement
  - W boson width measurement (analysis issues very similar to M_W)
  - Forward-backward asymmetry (A_{FB}) in Z boson decays
    - On-peak and high-mass

Decay Angular Coefficients in Z boson decay

- Measurements using 2.1 fb^{-1}

$$d\sigma/d\cos\theta d\varphi \propto (1+\cos^2\theta) + 0.5A_0(1-3\cos^2\theta) + A_1 \sin 2\theta \cos\varphi$$

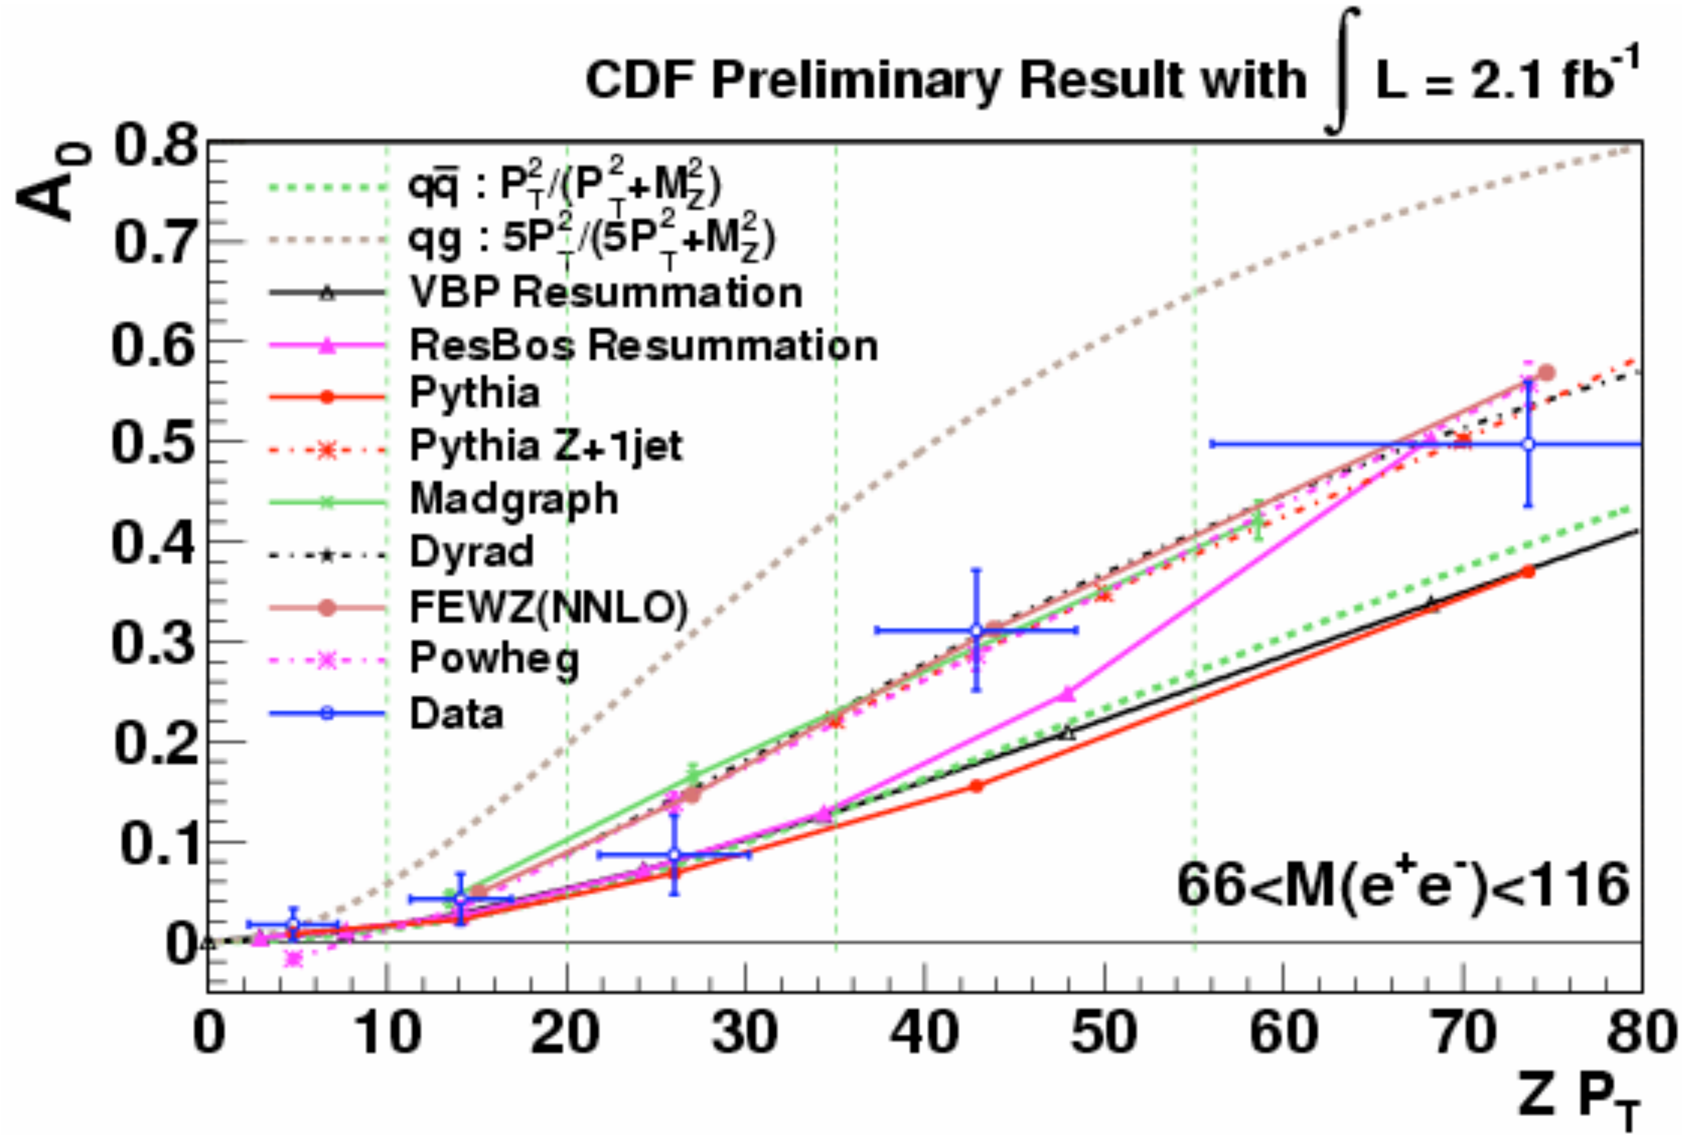
$$+ 0.5A_2 \sin^2\theta \cos 2\varphi + A_3 \sin\theta \cos\varphi + A_4 \cos\theta + A_5 \sin^2\theta \sin 2\varphi$$

$$+ A_6 \sin 2\theta \sin\varphi + A_7 \sin\theta \sin\varphi$$

Important to check theoretical calculations, which feed into other precision measurements (eg. M_W measurement in the case of W boson's decay angular coefficients)

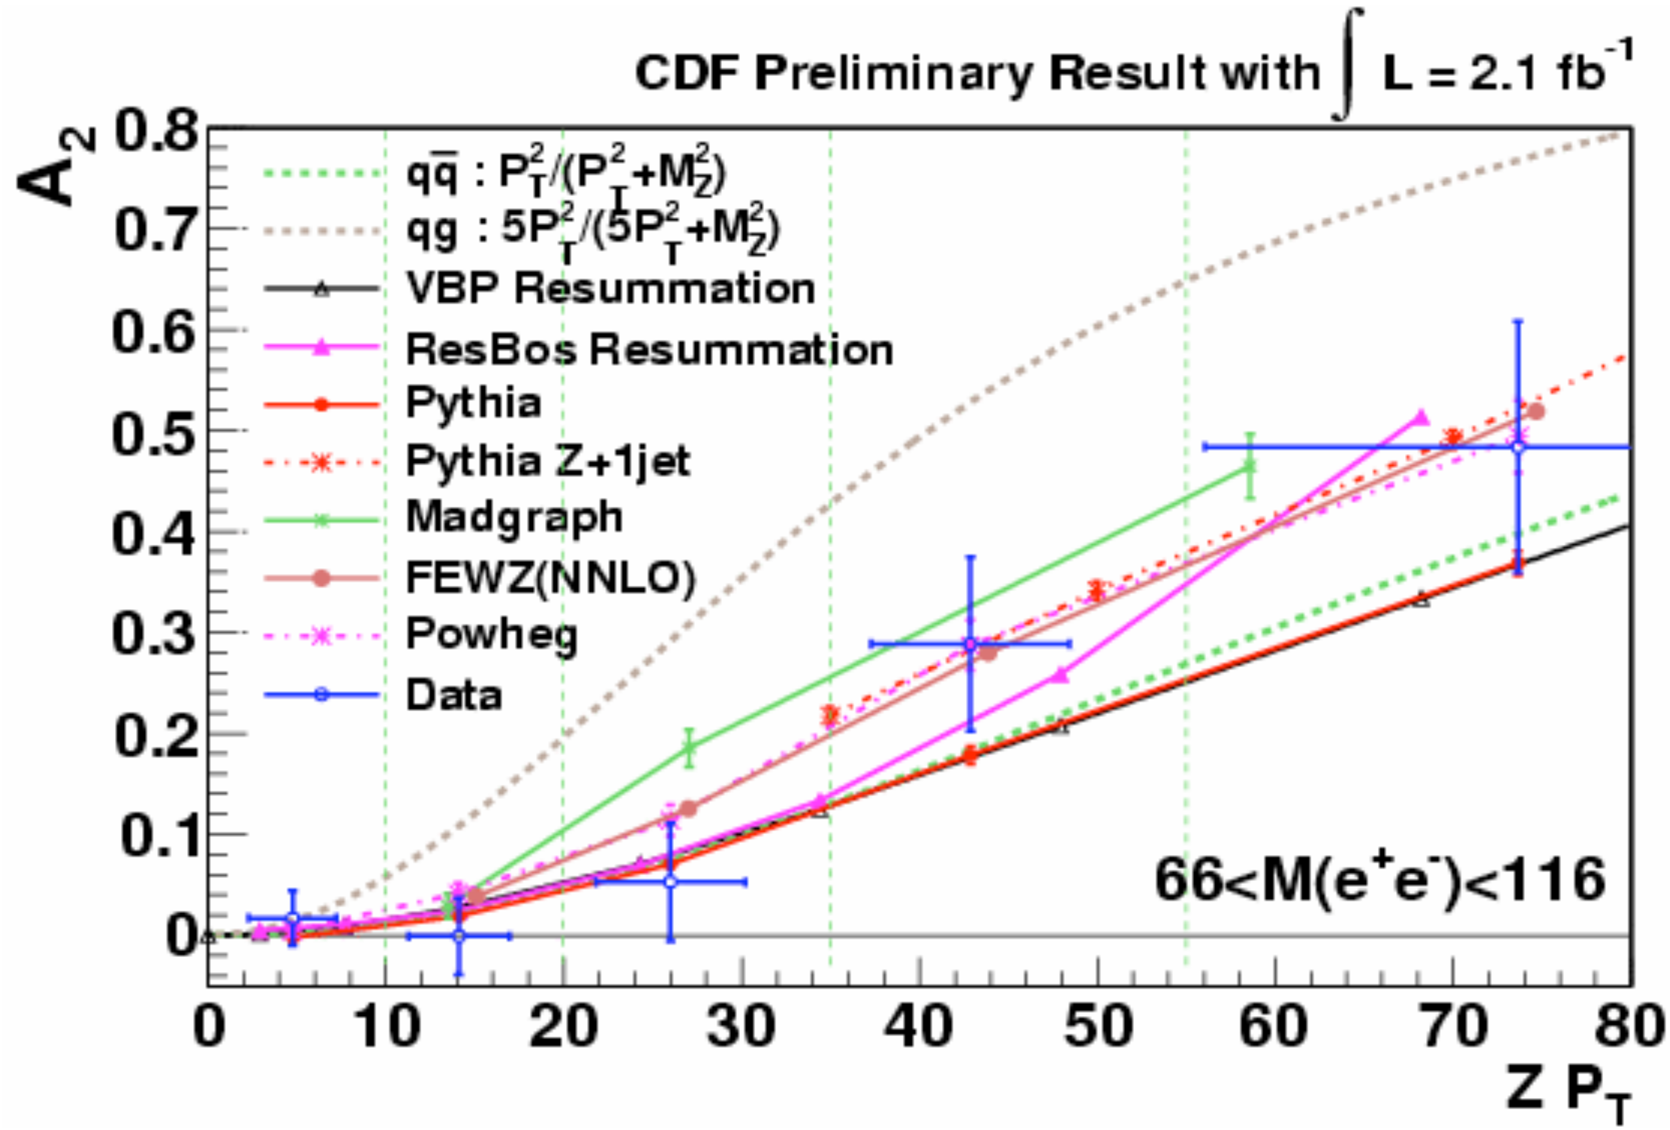
Decay Angular Coefficients in Z boson decay

- Uncertainty dominated by statistical uncertainty



Decay Angular Coefficients in Z boson decay

- Lam-Tung relation for spin-1 gluons: $A_2 = A_0$ confirmed

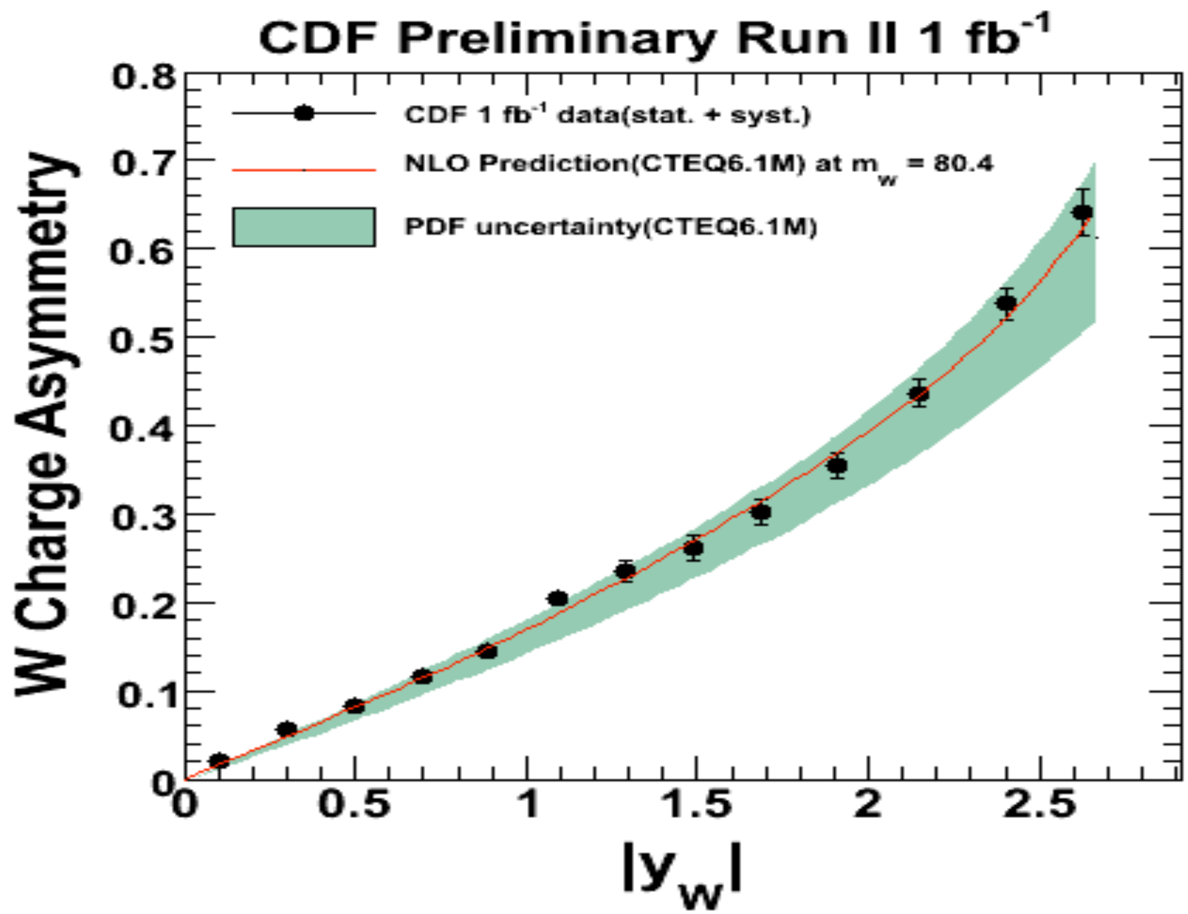


W charge asymmetry vs W rapidity

- Traditionally, lepton charge asymmetry is measured; V-A decay of W boson dilutes the observed lepton asymmetry
- CDF has also used $p_T(W)$ measured in the event, and M_W to measure asymmetry vs boson rapidity directly
- Removes V-A dilution

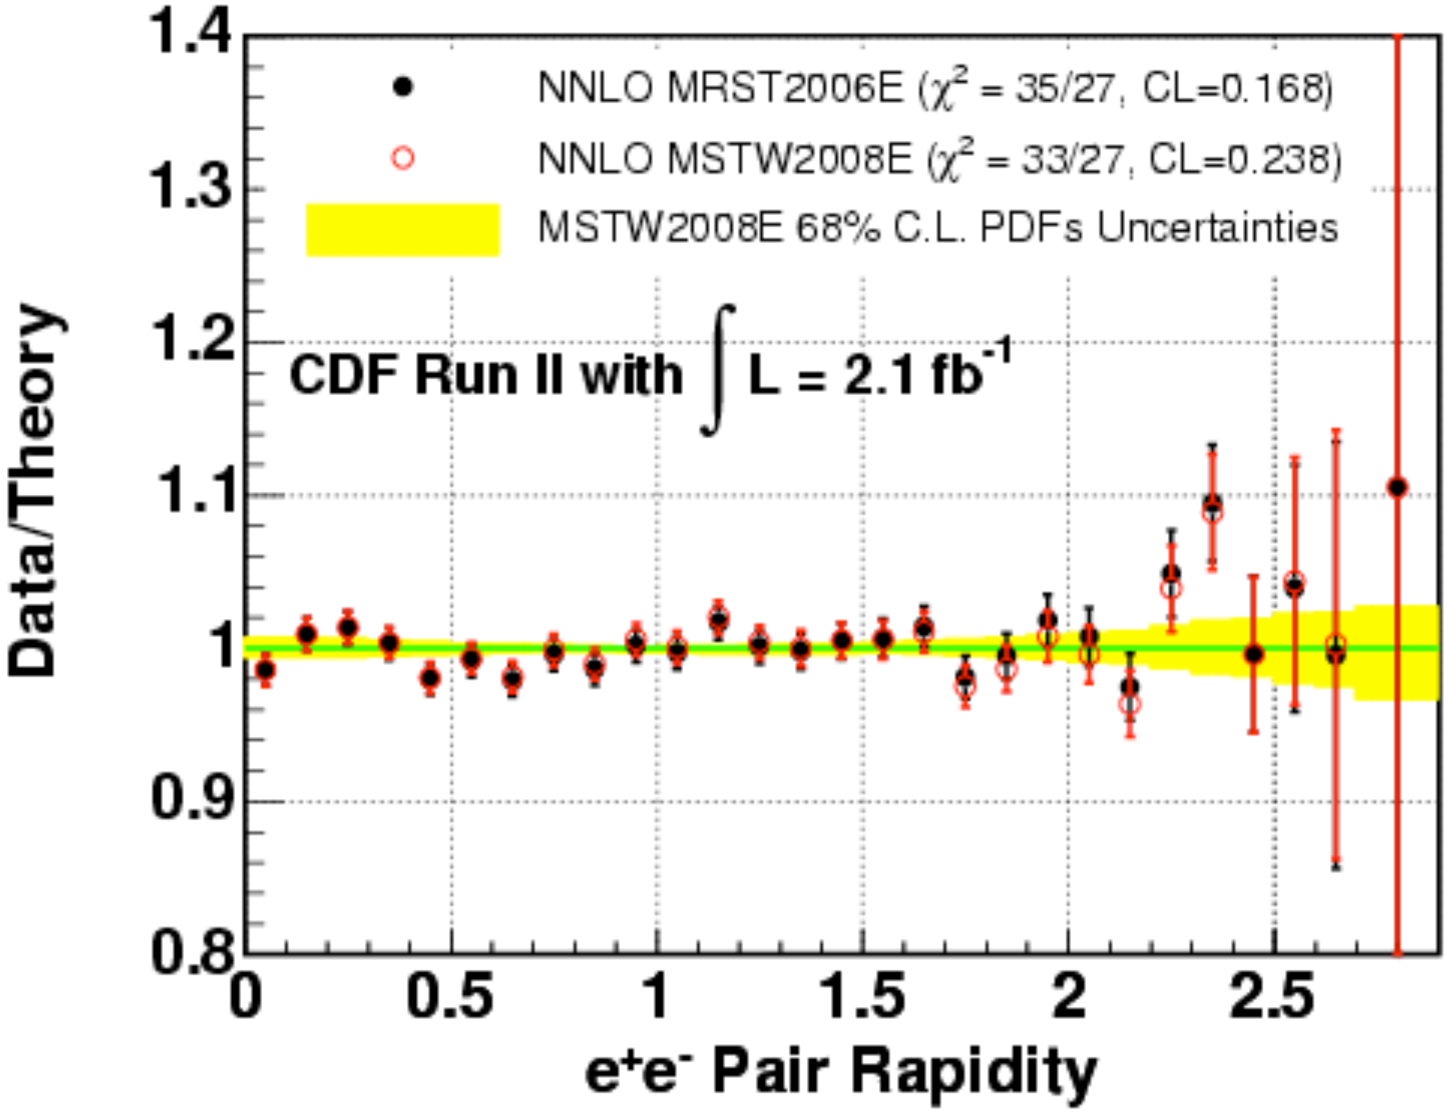
  At the expense of small additional systematics due to recoil

- At Tevatron, very powerful in constraining relevant PDFs



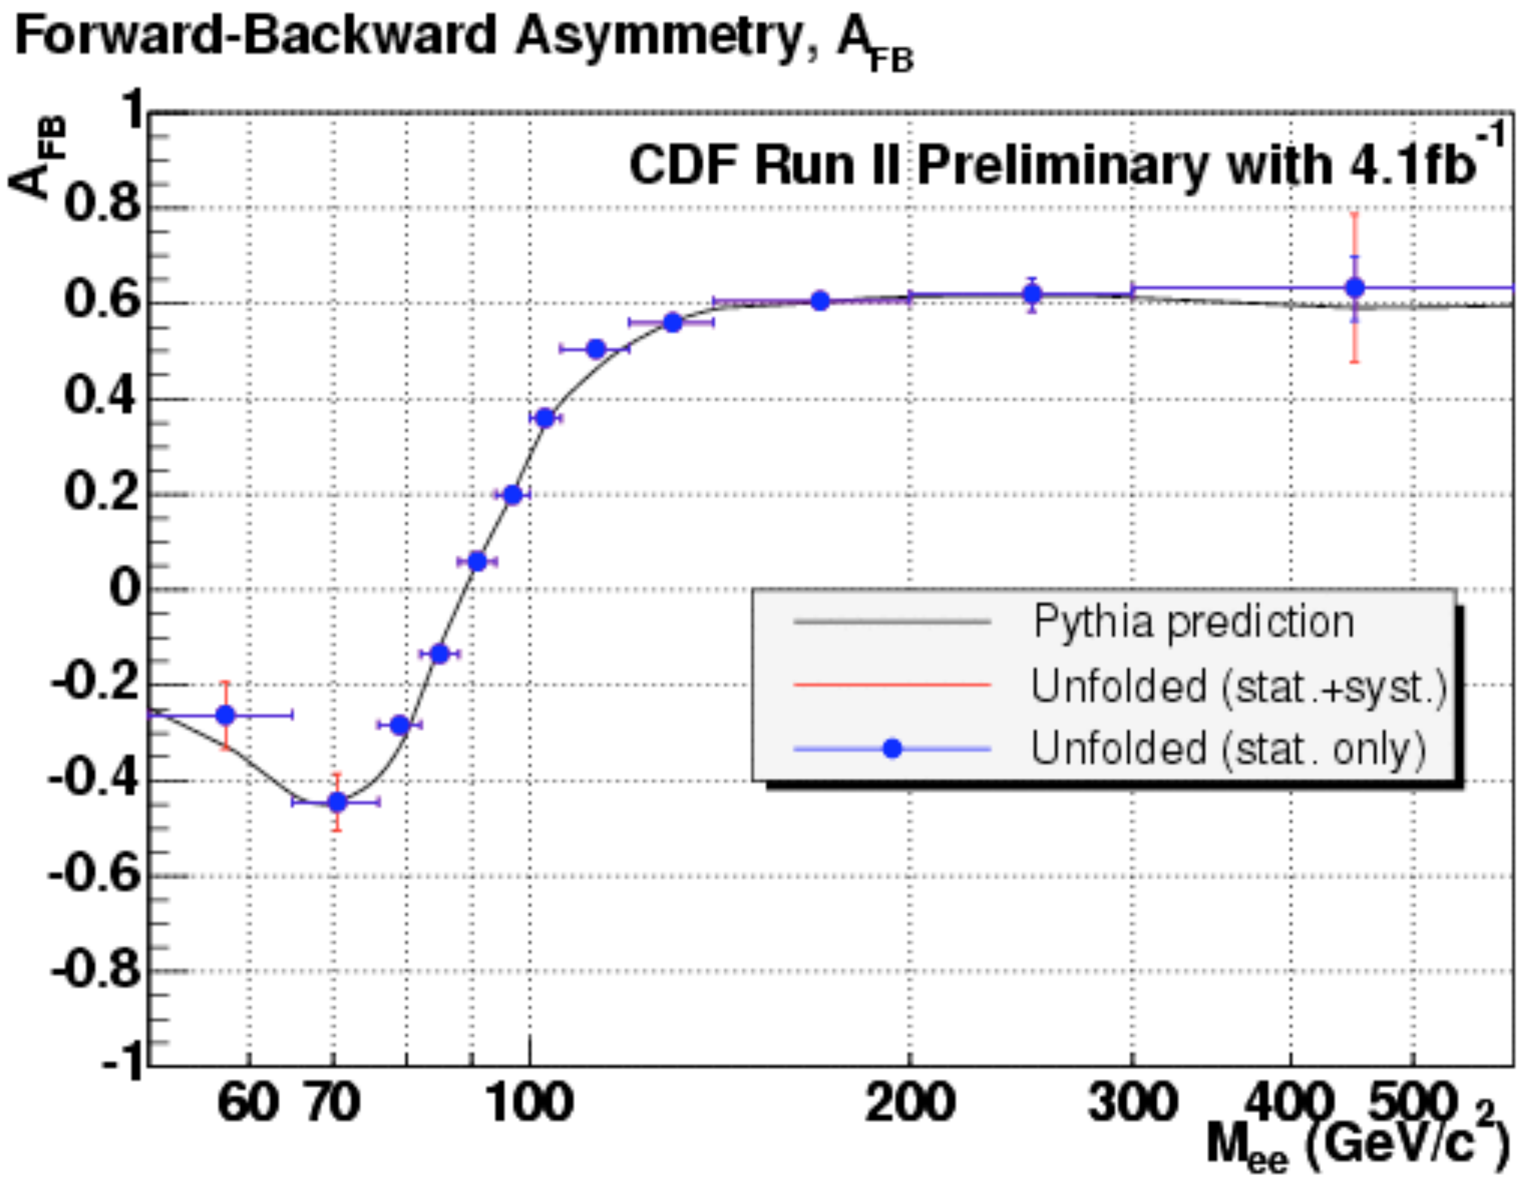
Rapidity distribution of Drell-Yan

- Powerful (and independent of W charge asymmetry) constraint on PDFs

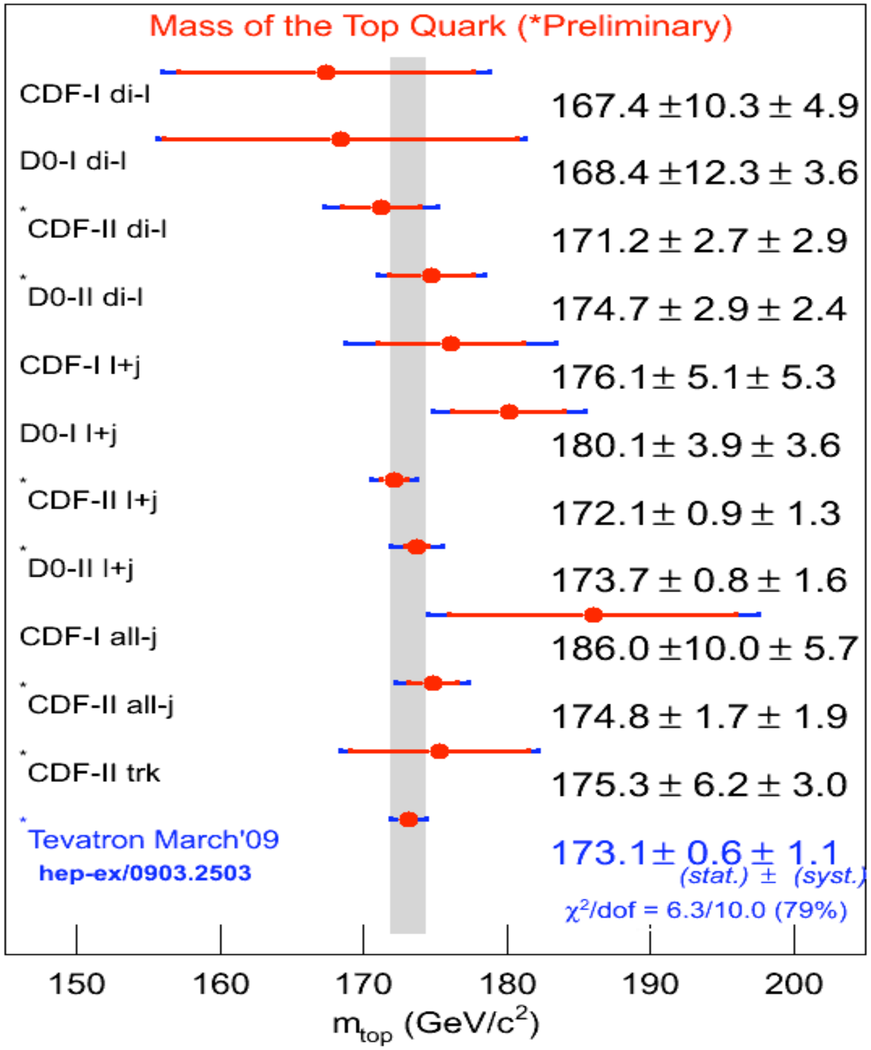


Forward-backward Asymmetry in Drell-Yan

- Z-pole not yet competitive with LEP/SLD, but measurement at high mass is sensitive to new physics (eg, Z') via interference



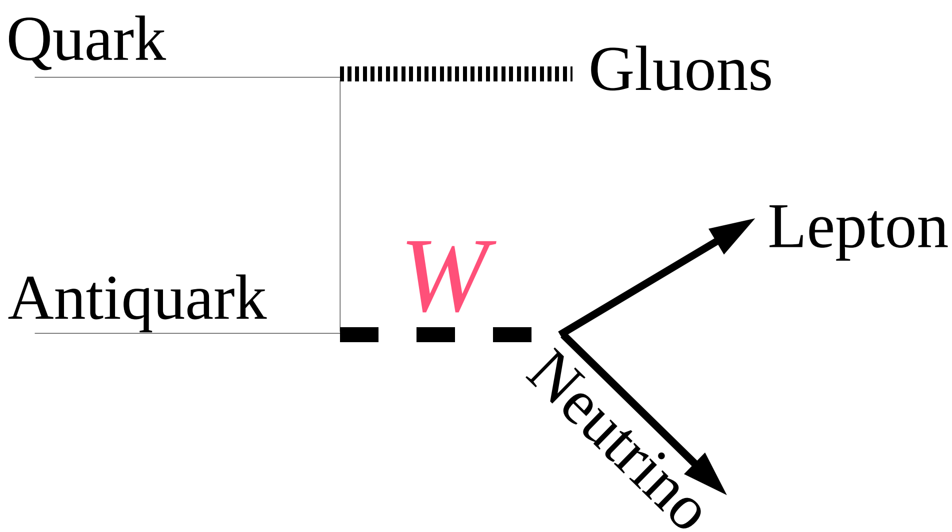
Progress on M_{top} at the Tevatron

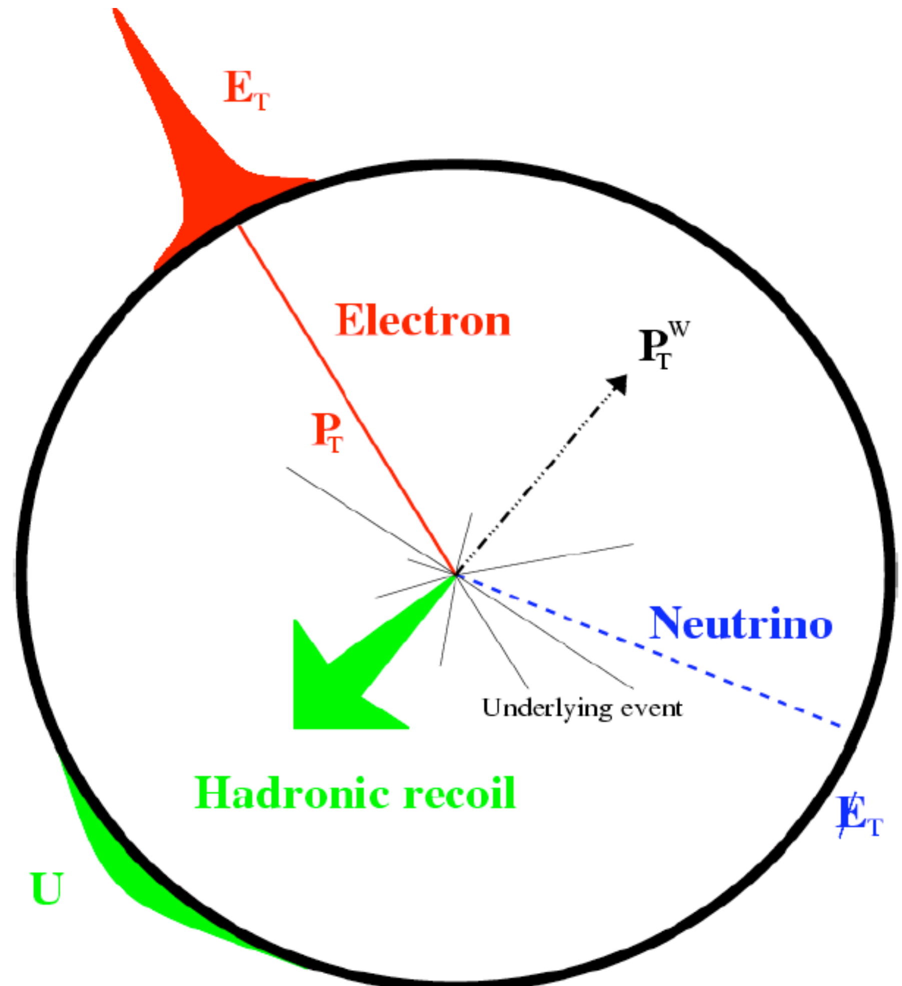


- From the Tevatron, δM_{top} = 1.3 GeV => $\delta M_H / M_H$ = 11%
- equivalent δM_W = 8 MeV for the same Higgs mass constraint
- Current world average δM_W = 23 MeV
  - progress on δM_W now has the biggest impact on Higgs constraint!

W Mass Analysis Strategy

W Boson Production at the Tevatron





Quark-antiquark annihilation dominates (80%)

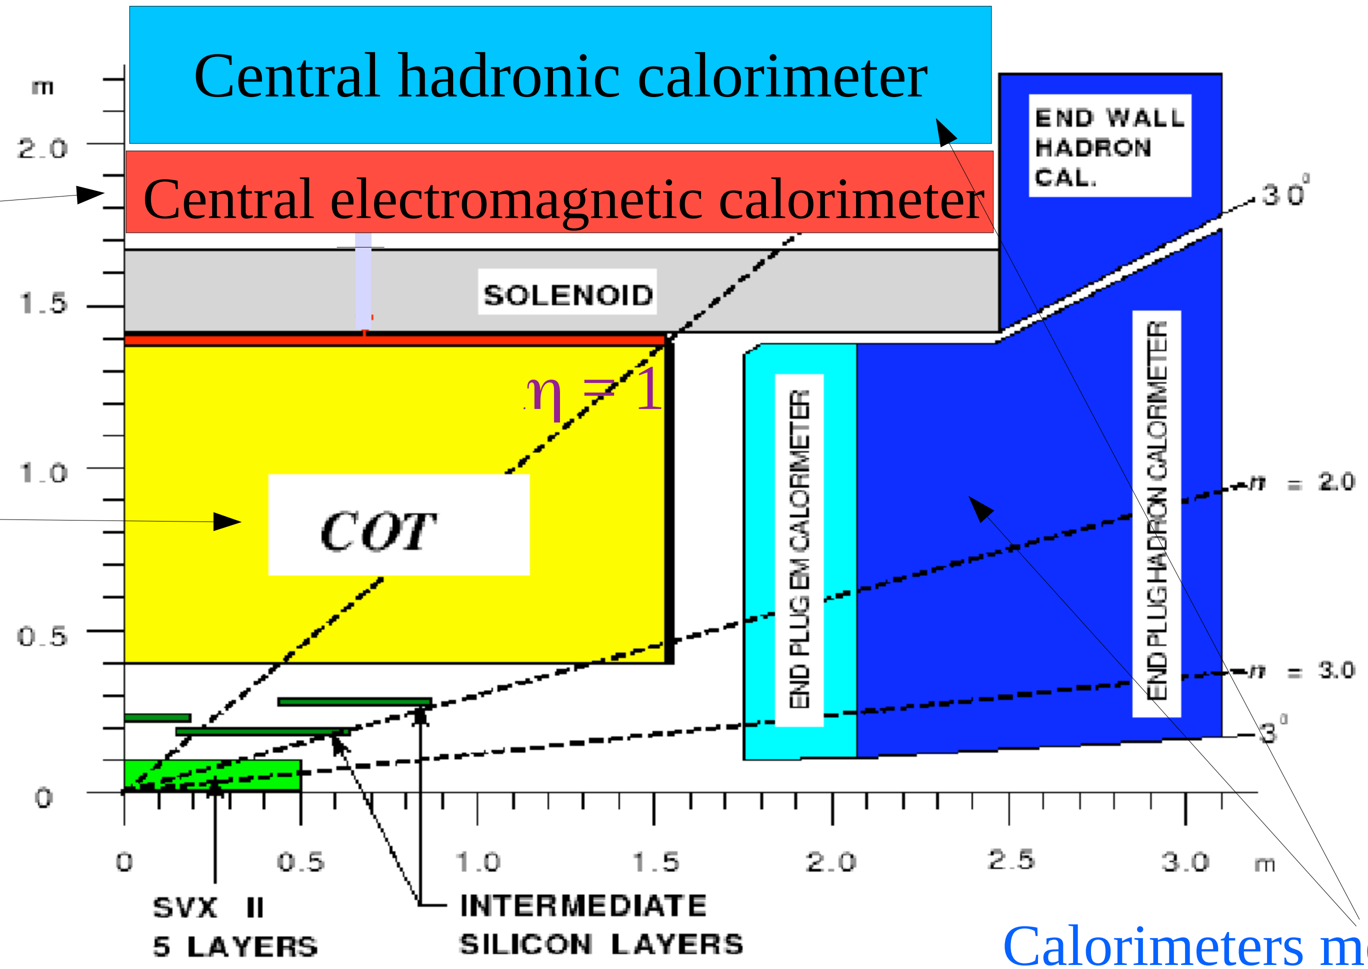
Lepton p_T carries most of *W* mass information, can be measured precisely (achieved 0.03%, aiming for 0.01%)

Initial state QCD radiation is *O*(10 GeV), measure as soft 'hadronic recoil' in calorimeter (calibrated to ~1%, aiming for 0.05%)
Pollutes *W* mass information, fortunately $p_T(W) \ll M_W$

Quadrant of Collider Detector at Fermilab (CDF)

EM calorimeter provides precise electron energy measurement

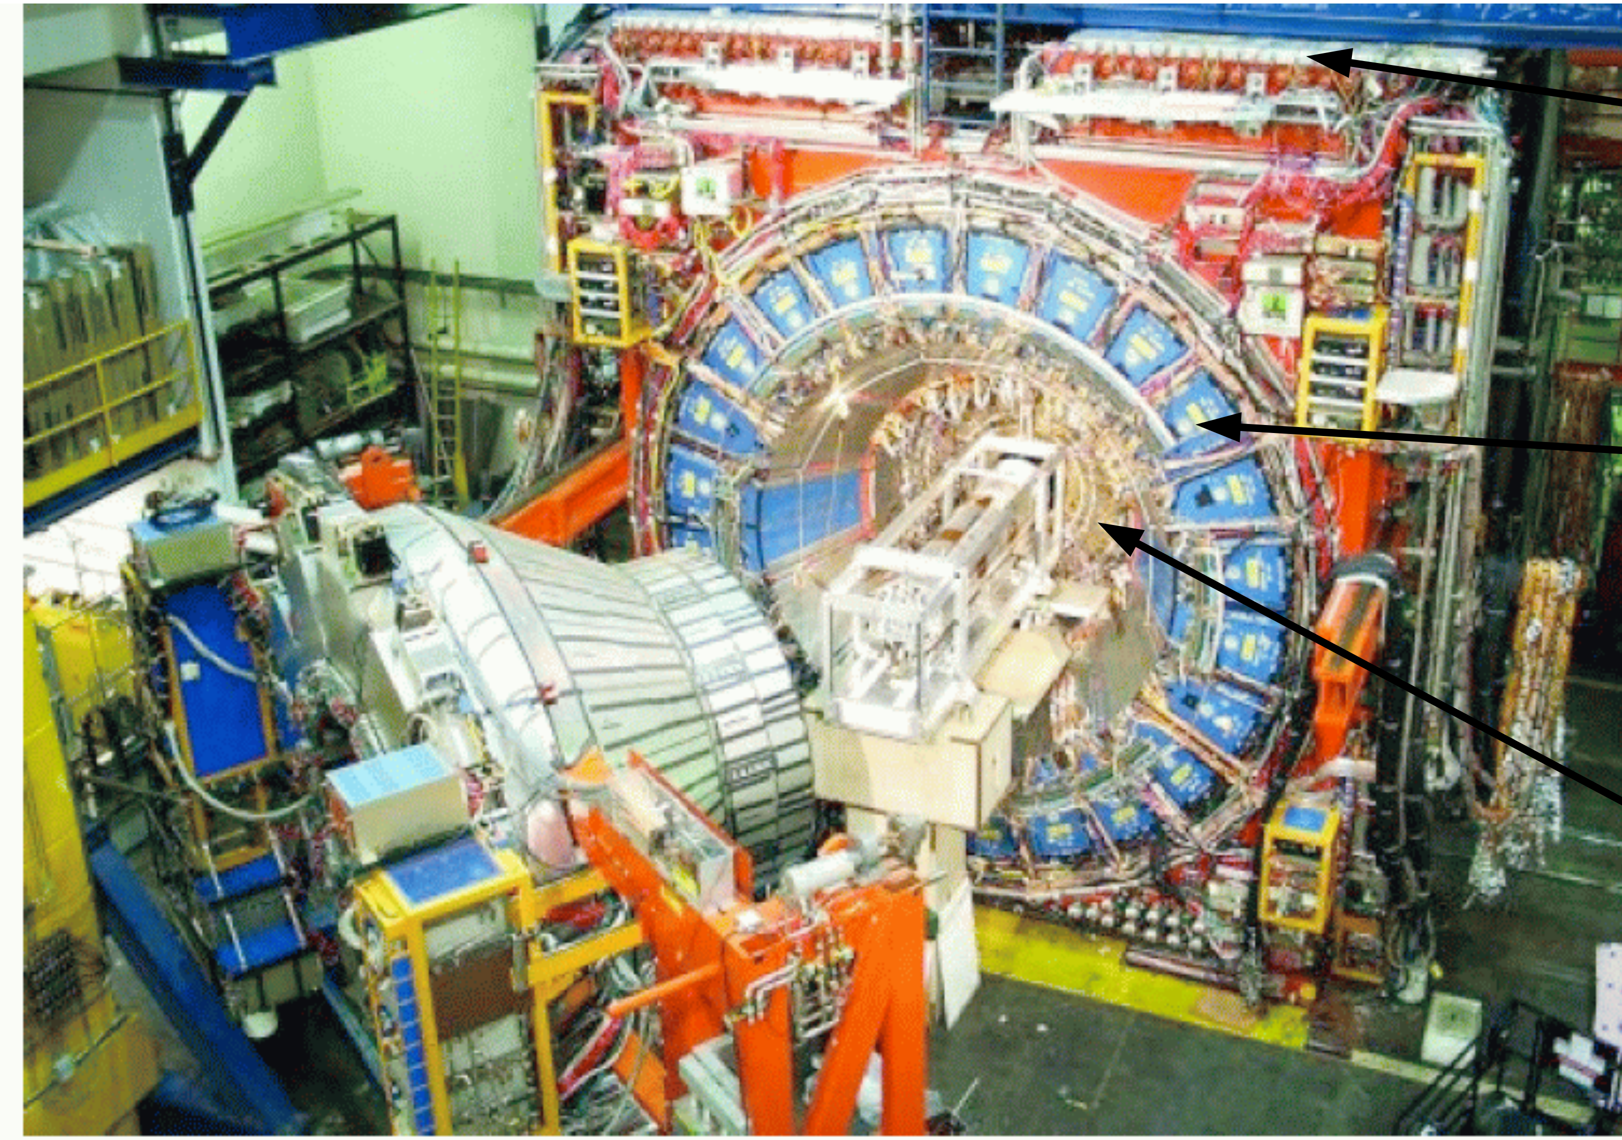
drift chamber provides precise lepton track momentum measurement



Calorimeters measure hadronic recoil particles

Select W and Z bosons with central (| **η** | < 1) leptons

Collider Detector at Fermilab (CDF)



Muon detector

Central hadronic calorimeter

Central outer tracker (COT)

CDF W & Z Data Samples

- W, Z, J/ψ and Upsilon decays triggered in the dilepton channel
- Analysis of 2.3 fb^{-1} data in progress
- CDF's analysis published in 2007, based on integrated luminosity (collected between February 2002 – September 2003):
  - Electron channel: L = 218 pb^{-1}
  - Muon channel: L = 191 pb^{-1}

Sample	Candidates
$W \to e\nu$	63964
$W \to \mu\nu$	51128
$Z \to e^+e^-$	2919
$Z \to \mu^+\mu^-$	4960

- Event selection gives fairly clean samples
  - W boson samples' mis-identification backgrounds ~ 0.5%

Founding Principle of CDF Analysis

Energy scale measurements drive the W mass measurement

- Develop an energy calibration procedure based on fundamental principles
  - Push the "first-principles" philosophy as far as it will go
- Measure the Z boson mass in three different ways
  - Dimuon mass using tracks
  - Dielectron mass using tracks
  - Dielectron mass using calorimeter cluster energies
- Consistency of these three Z boson mass measurements with LEP measurement (within quoted uncertainties) provides very strong validation of the fundamental understanding of the physics and detector model used for M_W measurement
  - Huge effort at CDF invested in demonstrating this validation, in order to build maximum confidence in M_W measurement
  - We believe this investment is needed to trust ultimate precision of 5-10 MeV on M_W at any hadron collider

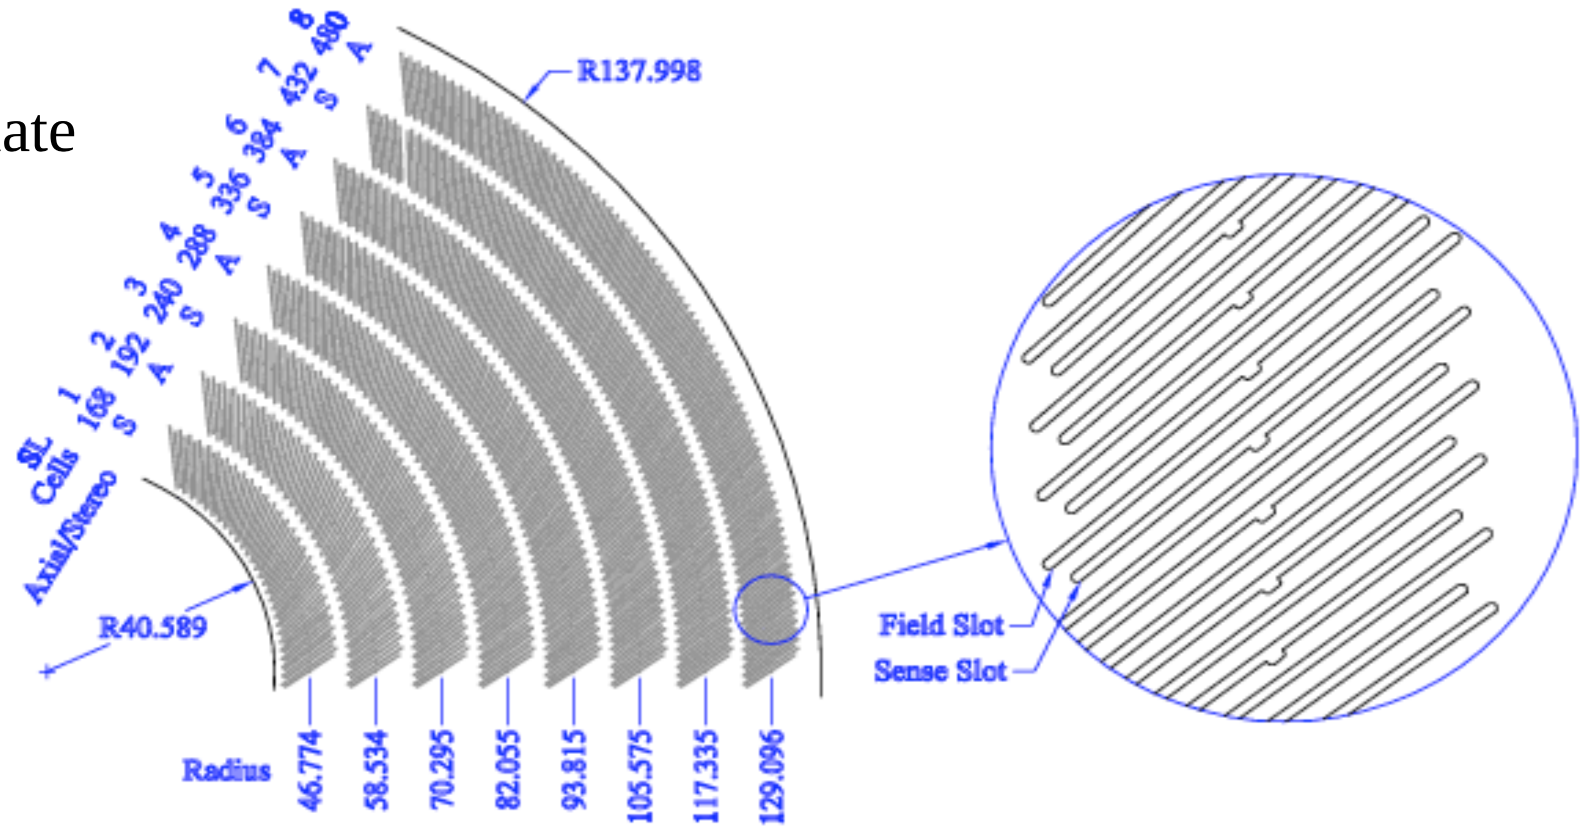
Outline of CDF Analysis

Energy scale measurements drive the W mass measurement

- Tracker Calibration
  - alignment of the central drift chamber (COT with ~2400 cells) using cosmic rays
  - COT momentum scale and tracker non-linearity constrained using $J/\psi \rightarrow \mu\mu$ and $\Upsilon \rightarrow \mu\mu$ mass fits
    - Confirmed using $Z \rightarrow \mu\mu$ mass fit and $Z \rightarrow ee$ mass fit using tracks
- EM Calorimeter Calibration
  - COT momentum scale transferred to EM calorimeter using a fit to the peak of the E/p spectrum, around E/p ~ 1 (an *in-situ* test beam)
  - Calorimeter energy scale confirmed using $Z \rightarrow ee$ mass fit
- Tracker and EM Calorimeter resolutions
- Hadronic recoil modelling
  - Characterized using p_T-balance in $Z \rightarrow ll$ events

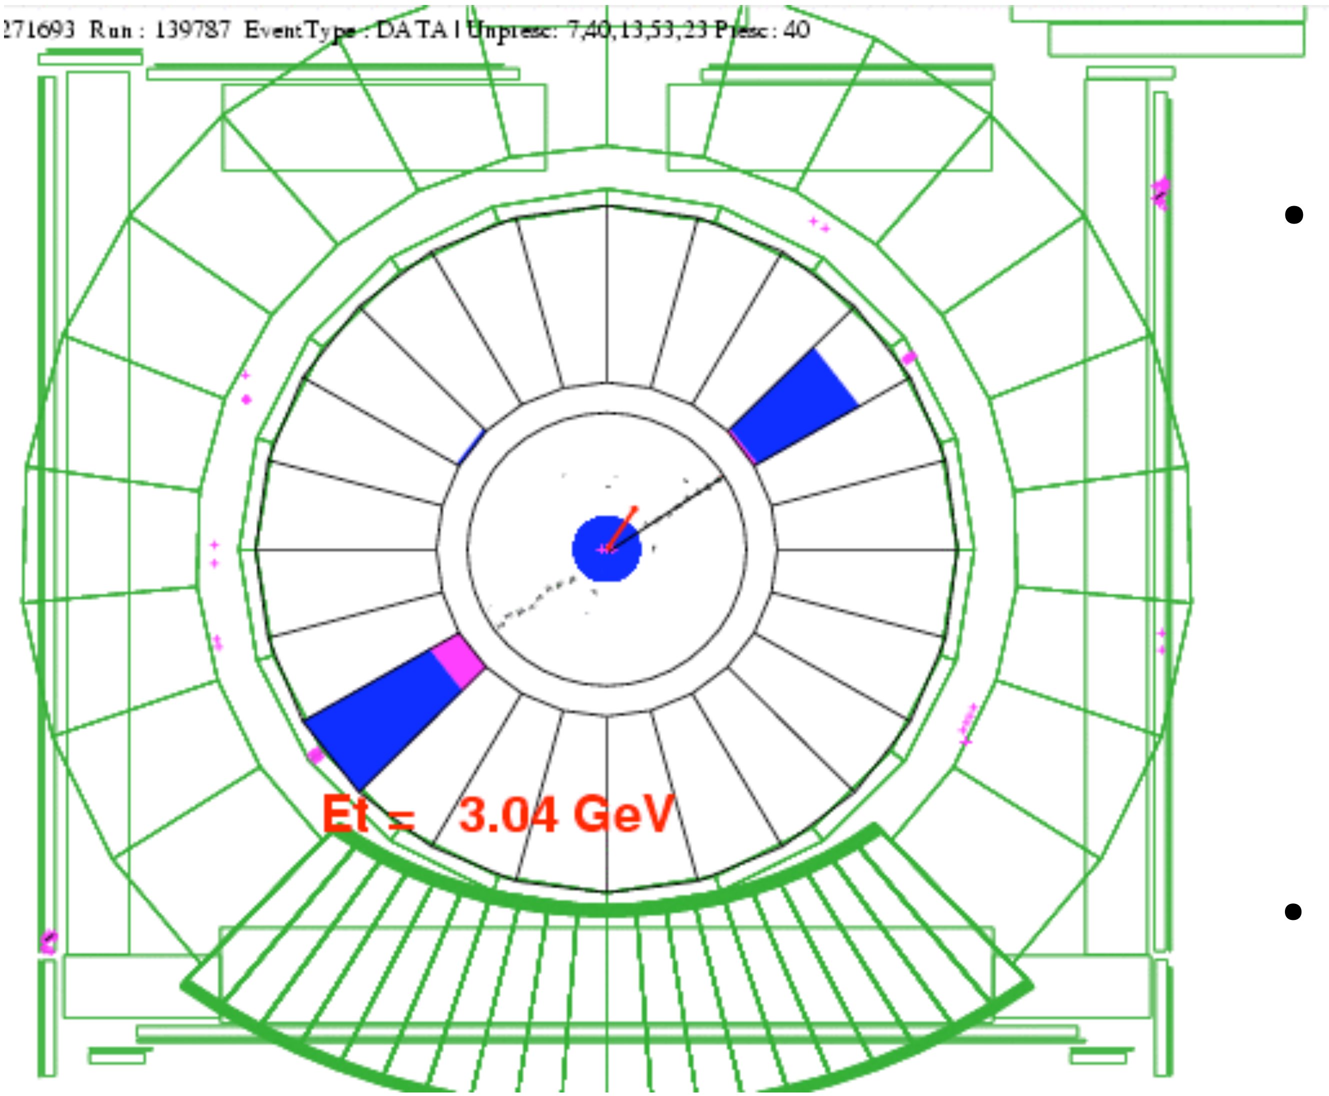
Drift Chamber (COT) Alignment

COT endplate geometry



Internal Alignment of COT

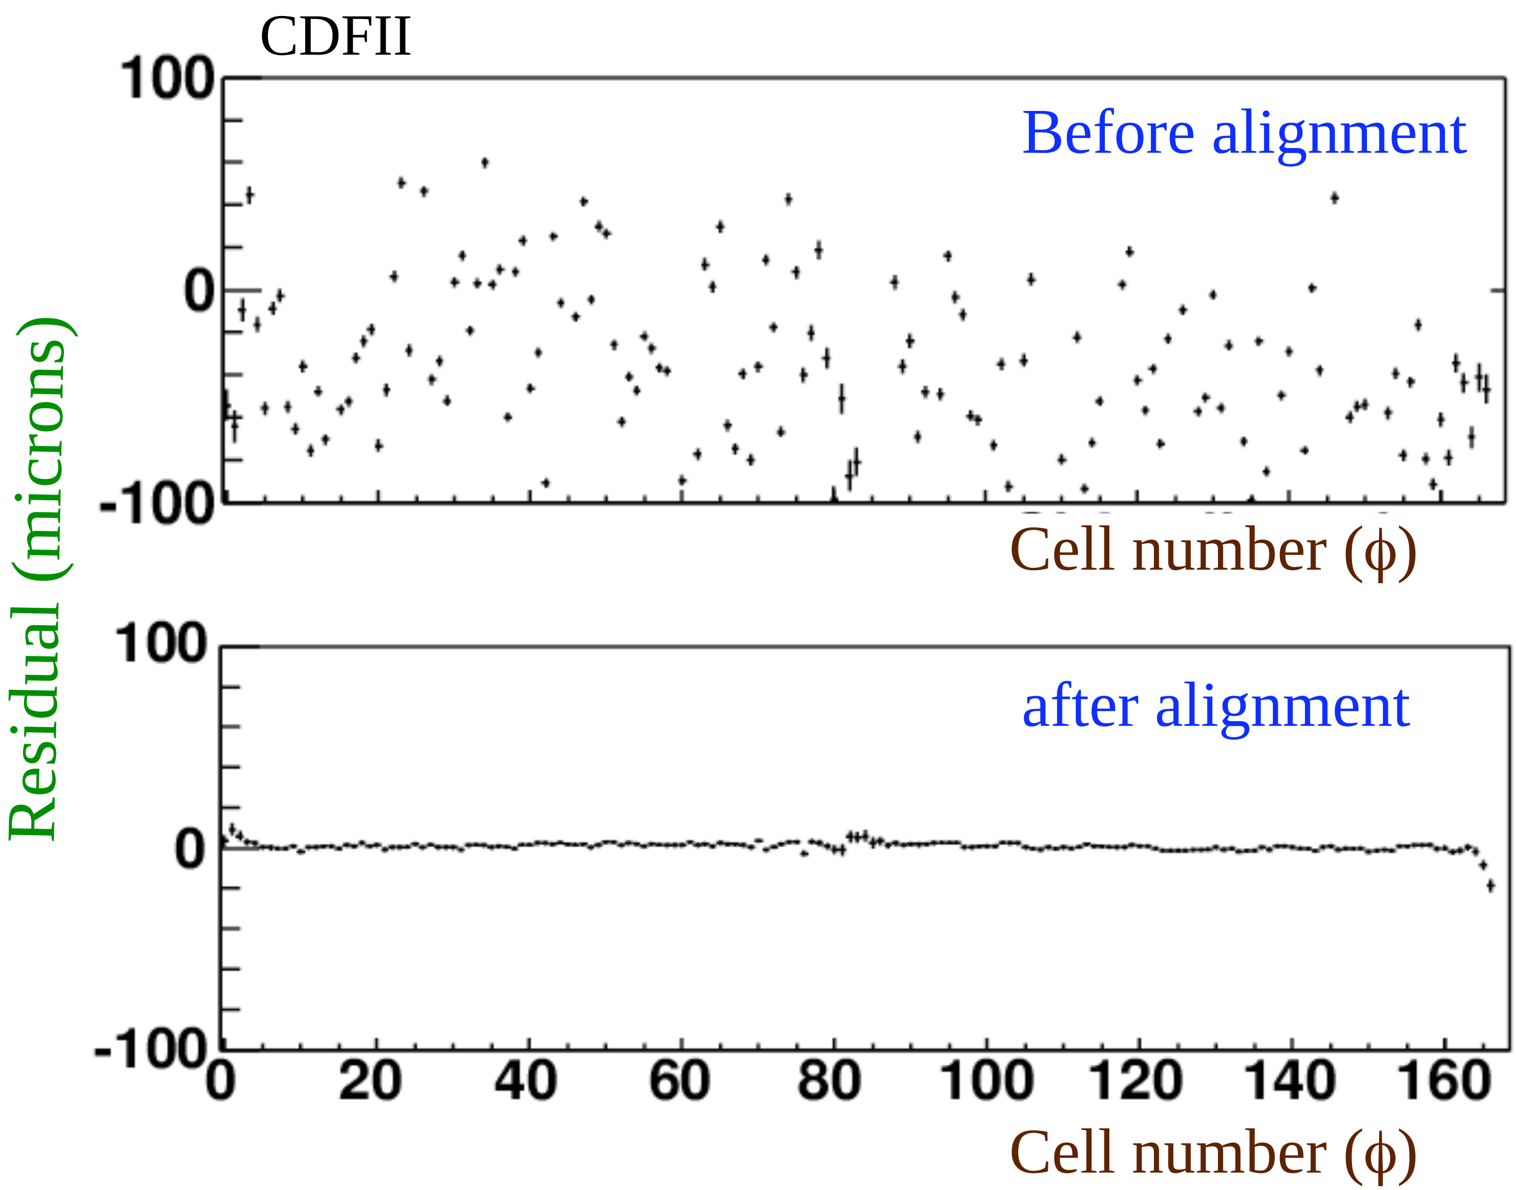
- Use a clean sample of ~200*k* cosmic rays for cell-by-cell internal alignment



- Fit COT hits on both sides simultaneously to a single helix (A Kotwal, H. Gerberich and C. Hays, NIM A 506, 110 (2003))
  - Time of incidence is a floated parameter

- Same technique being used on ATLAS and CMS

Residuals of COT cells after alignment



Final relative alignment of cells ~5 μm (initial alignment ~50 μm)

Many additional constraints on global deformations of tracking chamber

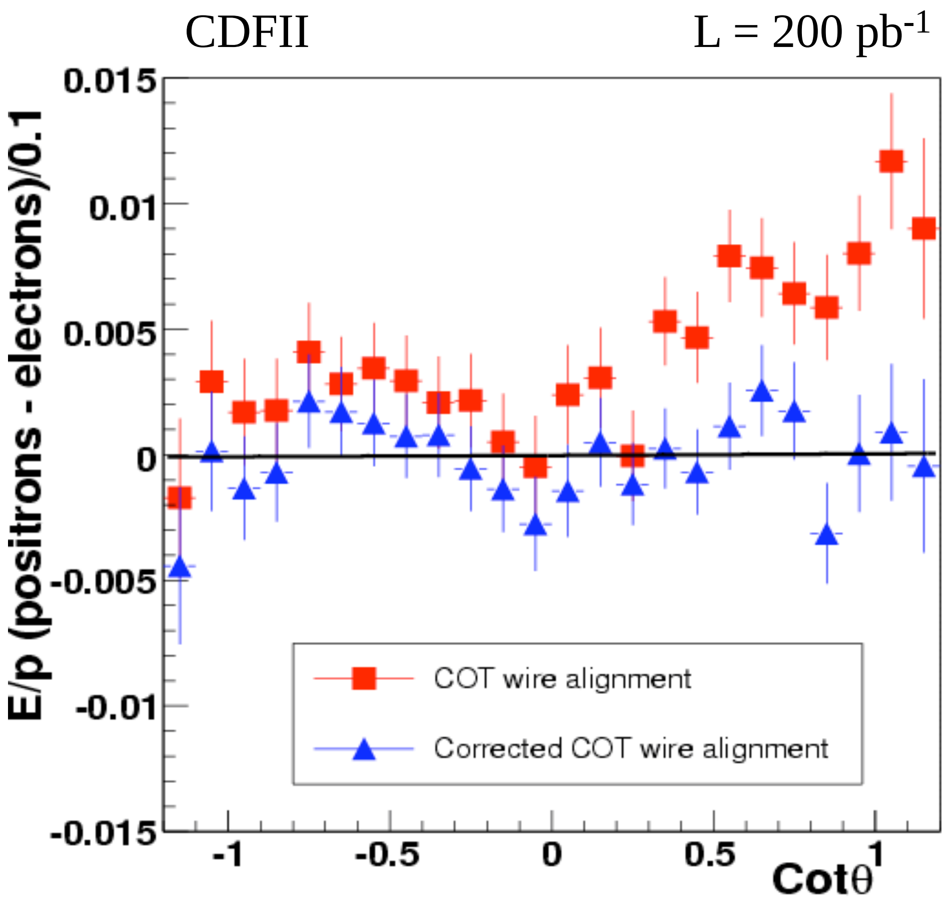
Constraints on Global Deformations of Drift Chamber

- Alignment based on Cosmic Rays provides powerful constraints on
  - Curl (coaxial rotations at different radii)
  - Twist (relative rotation of two end-plates)
  - Telescoping (relative longitudinal movements at different radii)
  - Gravitational sag of drift chamber wires
  - Electrostatic deflections of drift chamber wires

- We obtain substantial control on the fundamental degrees of freedom of the drift chamber misalignment

Cross-check of COT alignment

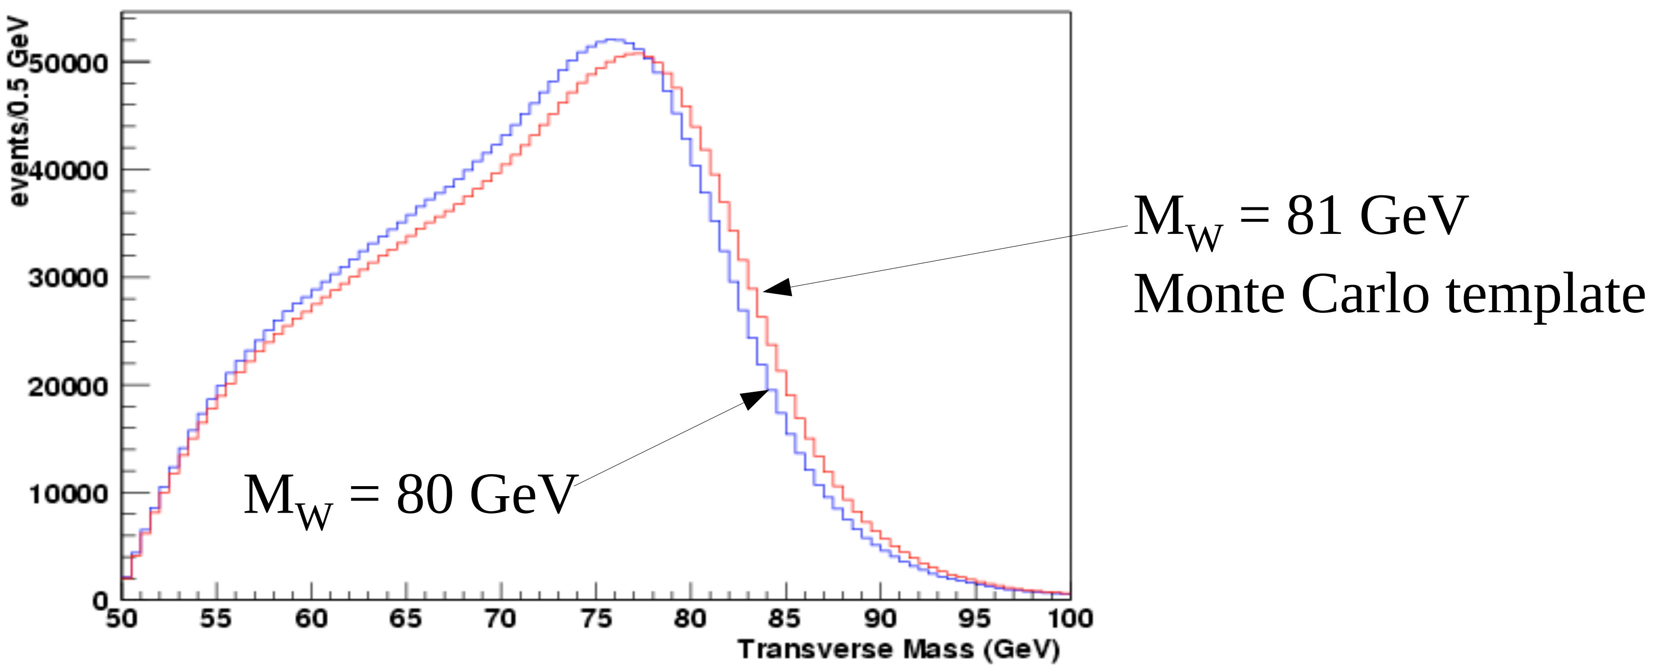
- Final cross-check and correction to track curvature based on difference of <E/p> for positrons *vs* electrons (red points)
- Smooth ad-hoc curvature corrections applied => δM_W = 6 MeV
- Systematic effects also relevant for LHC trackers



Signal Simulation and Fitting

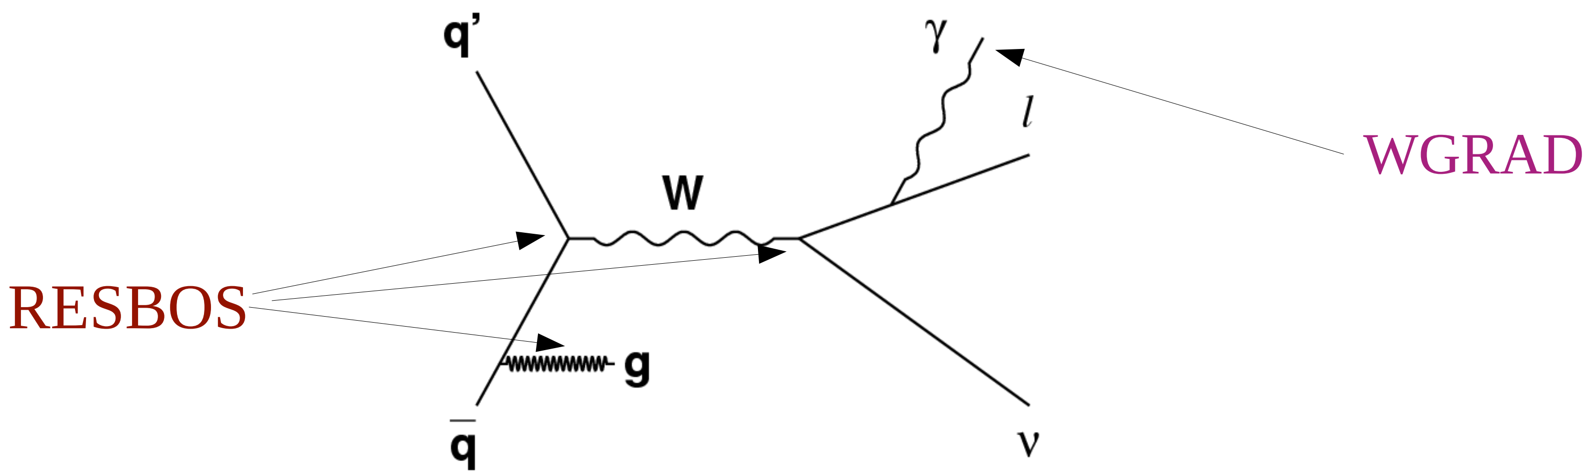
Signal Simulation and Template Fitting

- All signals simulated using a custom Monte Carlo
  - Generate finely-spaced templates as a function of the fit variable
  - perform binned maximum-likelihood fits to the data
- Custom fast Monte Carlo makes smooth, high statistics templates
  - And provides analysis control over fundamental physics inputs



- CDF (and D0) extract the W mass from three kinematic distributions: Transverse mass, charged lepton p_T and neutrino p_T : different recoil systematics

Generator-level Signal Simulation



- Generator-level input for W & Z simulation provided by RESBOS (C. Balazs & C.-P. Yuan, PRD56, 5558 (1997) and references therein), which
  - Calculates triple-differential production cross section, and p_T-dependent double-differential decay angular distribution
  - calculates boson p_T spectrum reliably over the relevant p_T range: includes tunable parameters in the non-perturbative regime at low p_T
- Radiative photons generated according to energy *vs* angle lookup table from WGRAD (U. Baur, S. Keller & D. Wackeroth, PRD59, 013002 (1998))

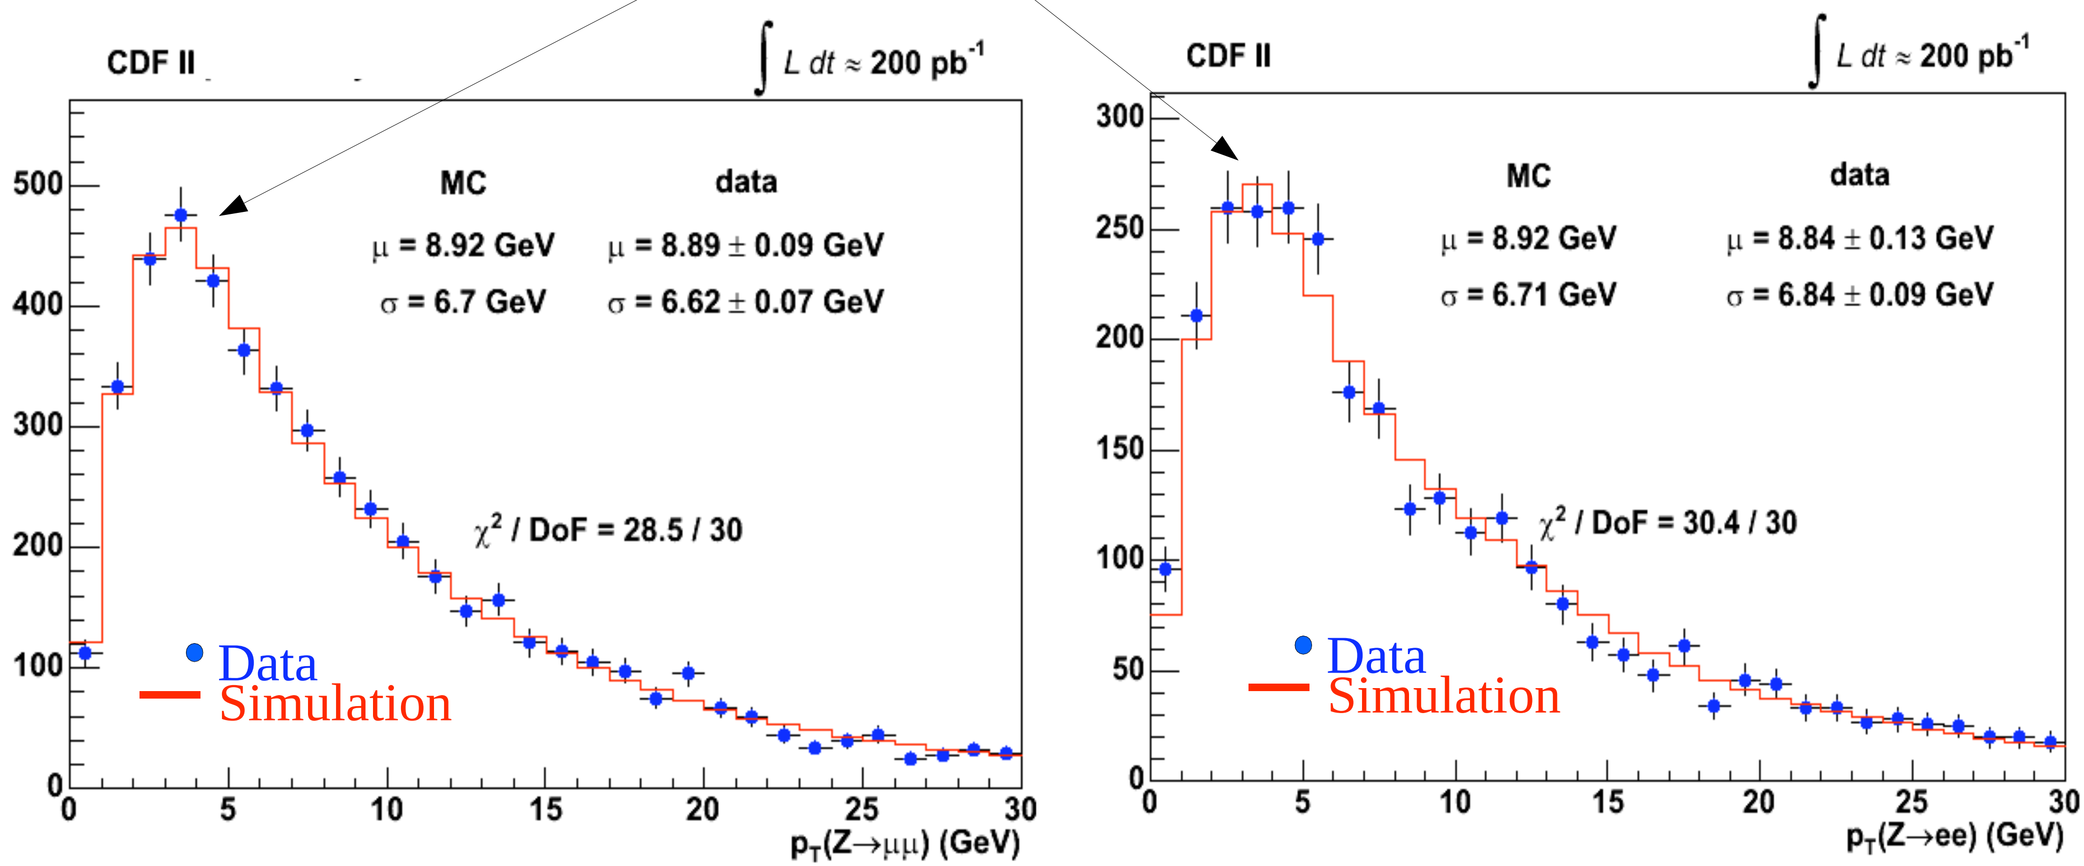
Constraining Boson p_T Spectrum

- Fit the non-perturbative parameter g_2 in RESBOS to $p_T(ll)$ spectra: find $g_2 = 0.685 \pm 0.048$

$\Delta M_W = 3$ MeV

  - Consistent with global fits (Landry *et al*, PRD67, 073016 (2003))
- Negligible effect of second non-perturbative parameter g_3

Position of peak in boson p_T spectrum depends on g_2

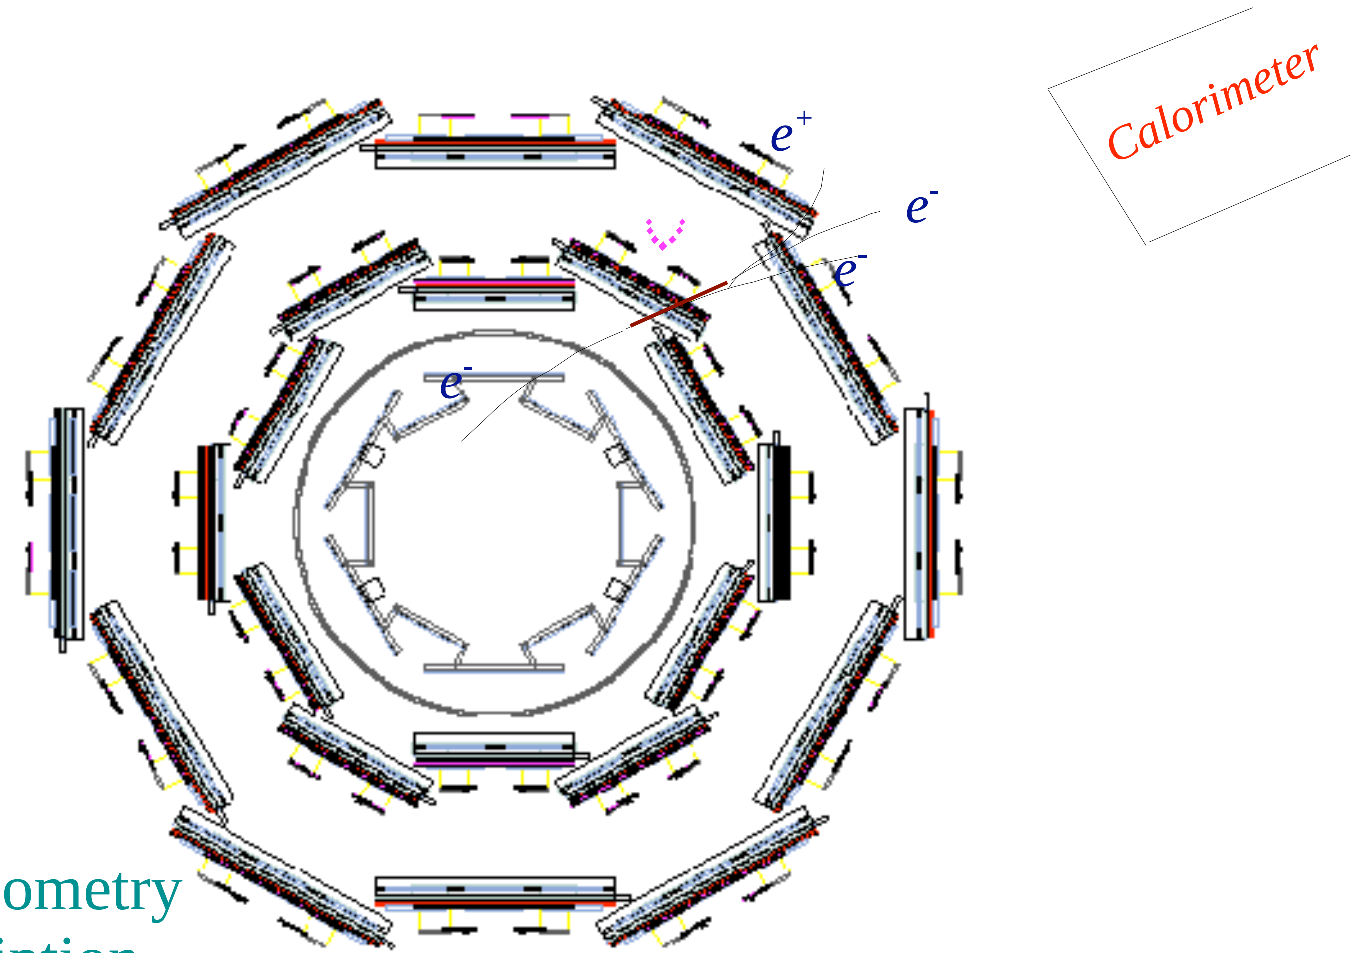


Custom Monte Carlo Detector Simulation

- A complete detector simulation of all quantities measured in the data
- First-principles simulation of tracking
  - Tracks and photons propagated through a high-resolution 3-D lookup table of material properties for silicon detector and drift chamber
  - At each material interaction, calculate
    - Ionization energy loss according to analytic formulae
    - Generate bremsstrahlung photons down to 0.4 MeV, using detailed cross section and spectrum calculations and LPM effect
    - Simulate photon conversion and compton scattering
    - Propagate bremsstrahlung photons and conversion electrons
    - Simulate multiple Coulomb scattering, including non-Gaussian tail
  - Deposit and smear hits on COT wires, perform full helix fit including beam-constraint

Fast Monte Carlo Detector Simulation

- A complete detector simulation of all quantities measured in the data
- First-principles simulation of tracking
  - Tracks and photons propagated through a high-resolution 3-D lookup table of material properties for silicon detector and drift chamber



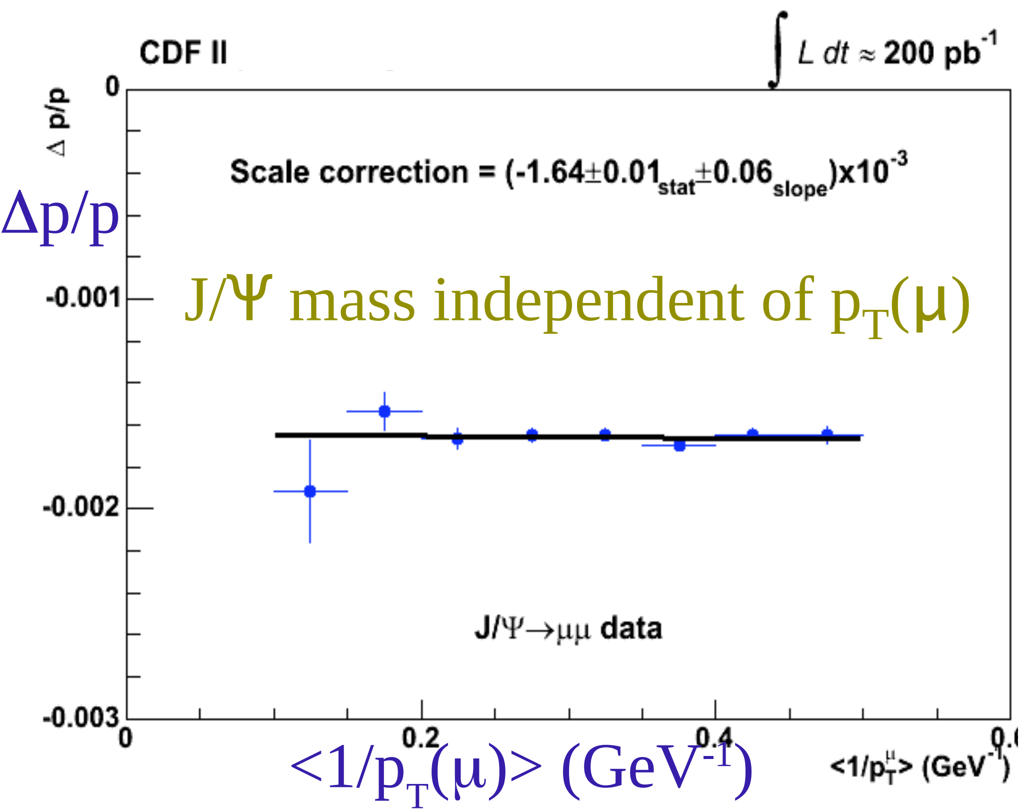
Silicon detector geometry
and material description

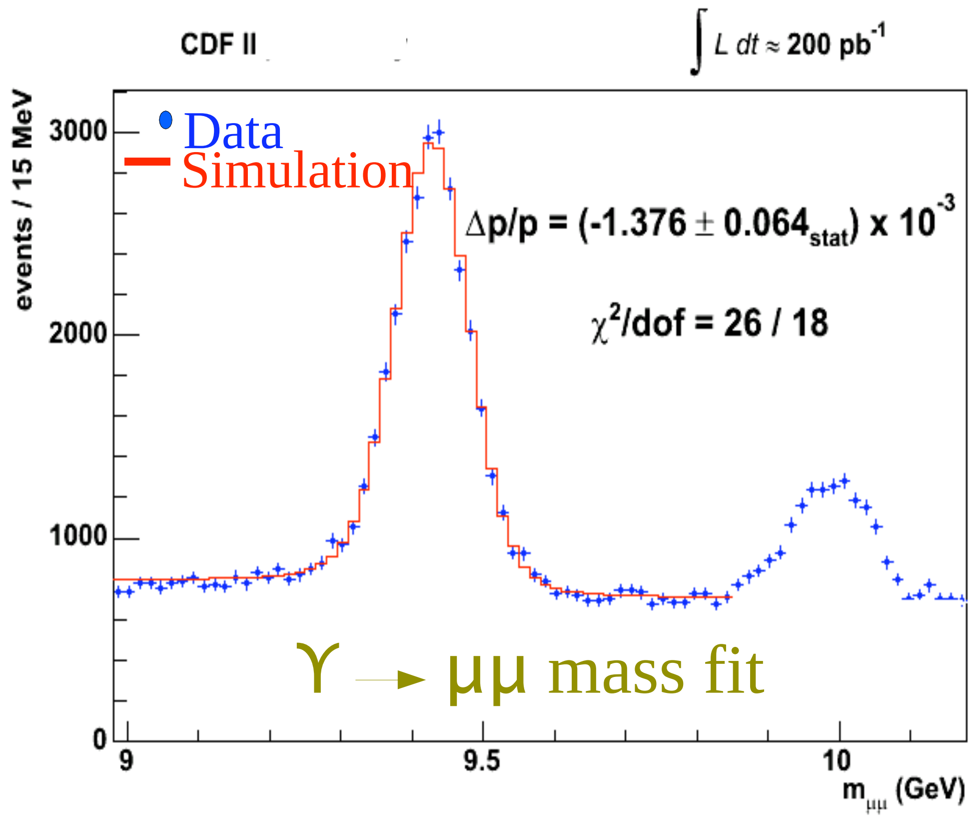
Tracking Momentum Scale

Tracking Momentum Calibration

- Set using $J/\Psi \rightarrow \mu\mu$ and $\Upsilon \rightarrow \mu\mu$ resonances
  - Measured to be consistent within total uncertainties

- Use J/Ψ to study and calibrate ionizing material accounting (6% correction needed)





Tracking Momentum Scale Systematics

Systematic uncertainties on momentum scale

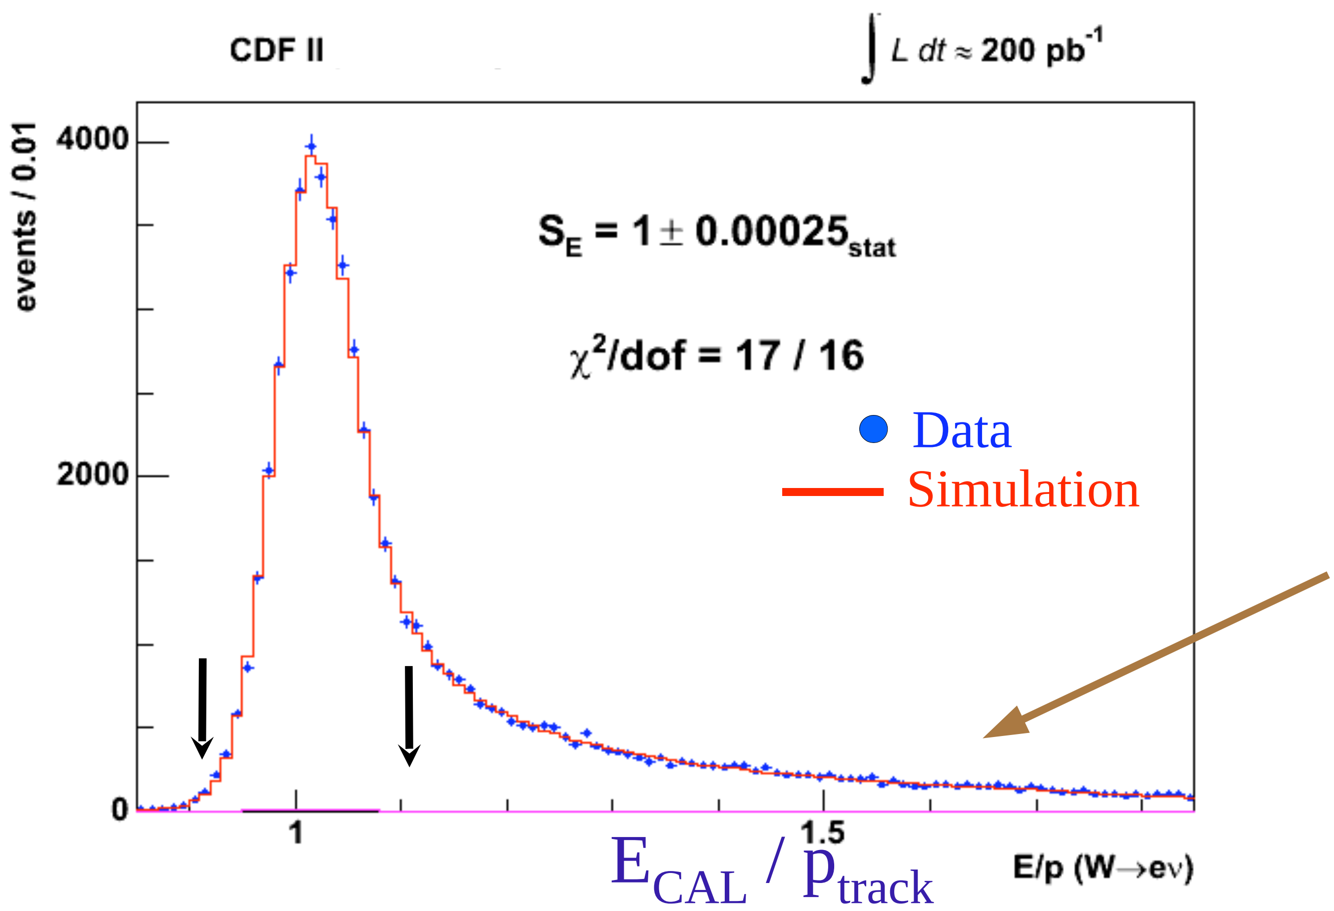
Source	J/ψ ($\times 10^{-3}$)	Υ ($\times 10^{-3}$)	Common ($\times 10^{-3}$)
QED and energy loss model	0.20	0.13	0.13
Magnetic field nonuniformities	0.10	0.12	0.10
Beam constraint bias	N/A	0.06	0
Ionizing material scale	0.06	0.03	0.03
COT alignment corrections	0.05	0.03	0.03
Fit range	0.05	0.02	0.02
p_T threshold	0.04	0.02	0.02
Resolution model	0.03	0.03	0.03
Background model	0.03	0.02	0.02
World-average mass value	0.01	0.03	0
Statistical	0.01	0.06	0
Total	0.25	0.21	0.17

Uncertainty dominated by QED radiative corrections and magnetic field non-uniformity

EM Calorimeter Response

Electromagnetic Calorimeter Calibration

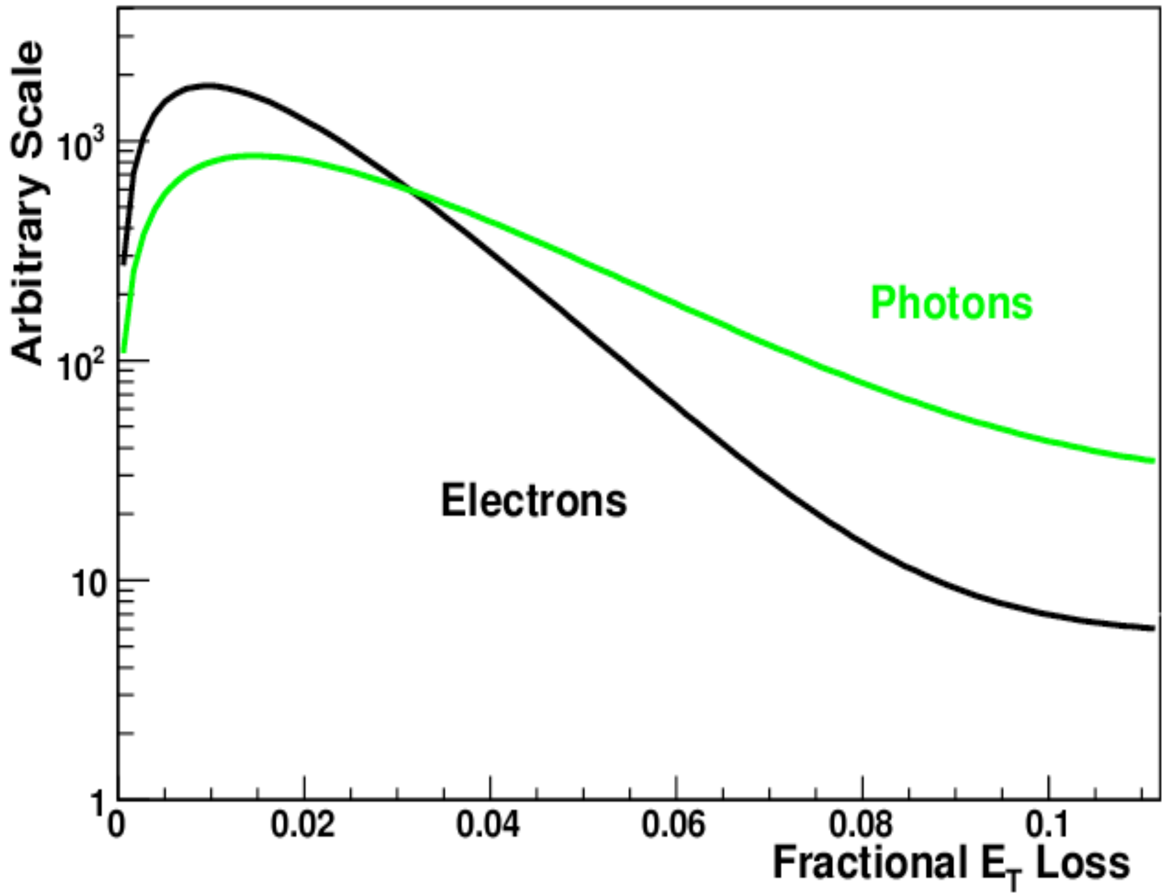
- E/p peak from $W \rightarrow e\nu$ decays provides EM calorimeter calibration relative to the tracker
  - Calibration performed in bins of electron energy



Tail region of E/p spectrum used for tuning model of radiative material

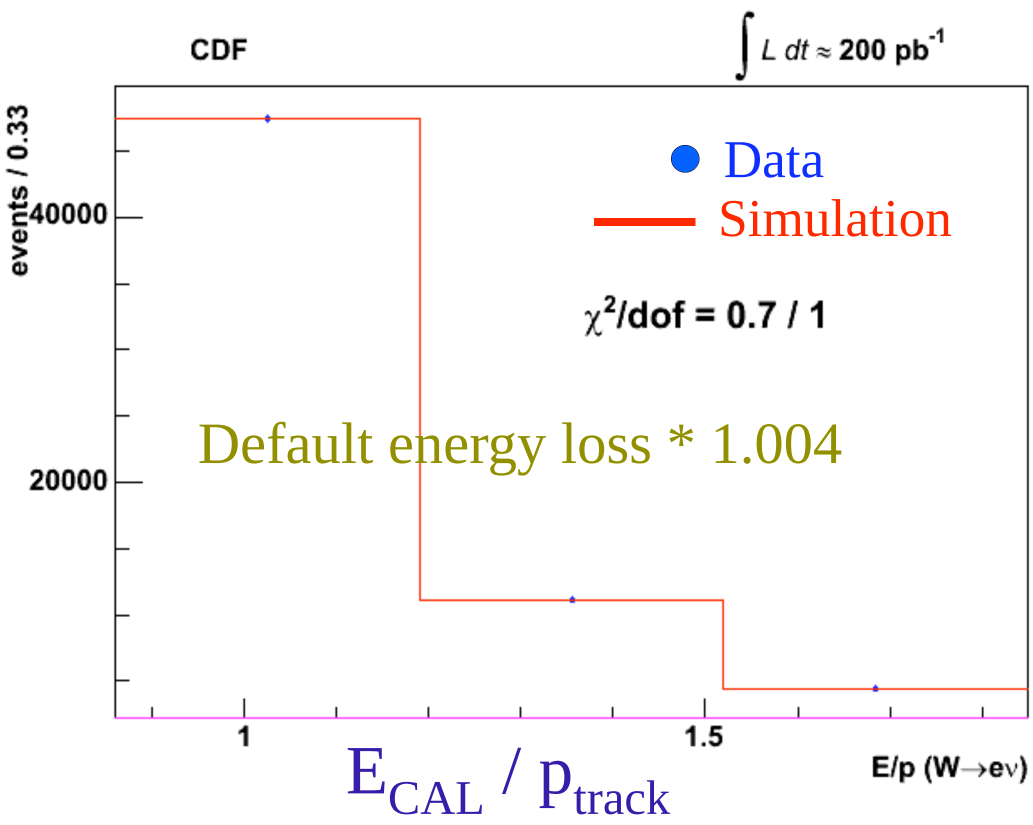
Calorimeter Simulation for Electrons and Photons

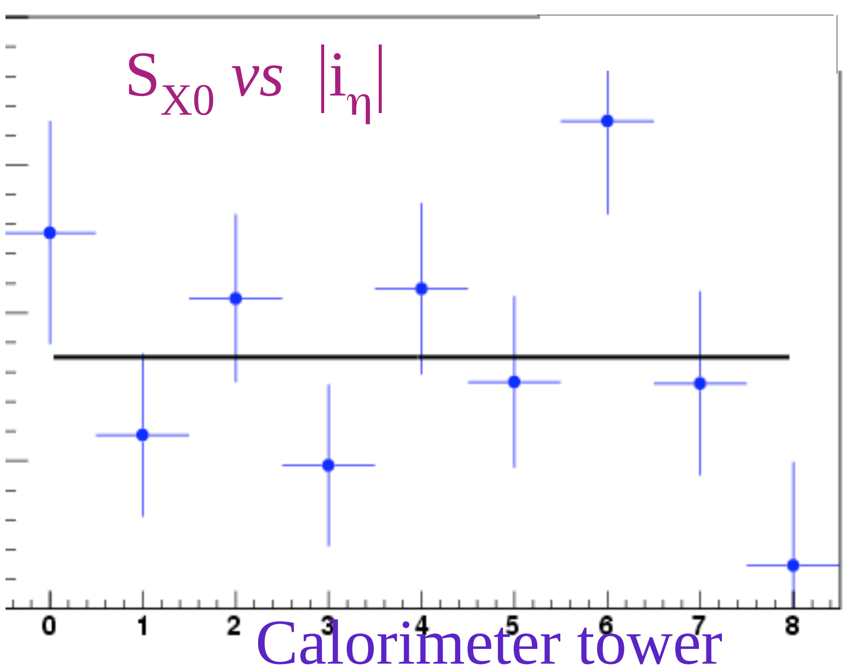
- Distributions of energy loss calculated based on expected shower profiles as a function of E_T
  - Leakage into hadronic calorimeter
  - Absorption in the coil
  - Relevant for E/p lineshape



Consistency of Radiative Material Model

- Excellent description of E/p spectrum tail
- radiative material tune factor: $S_{X0} = 1.004 \pm 0.009_{stat} \pm 0.002_{background}$ achieves consistency with E/p spectrum tail
  - CDF detector geometry confirmed as a function of pseudorapidity: S_{MAT} independent of pseudorapidity

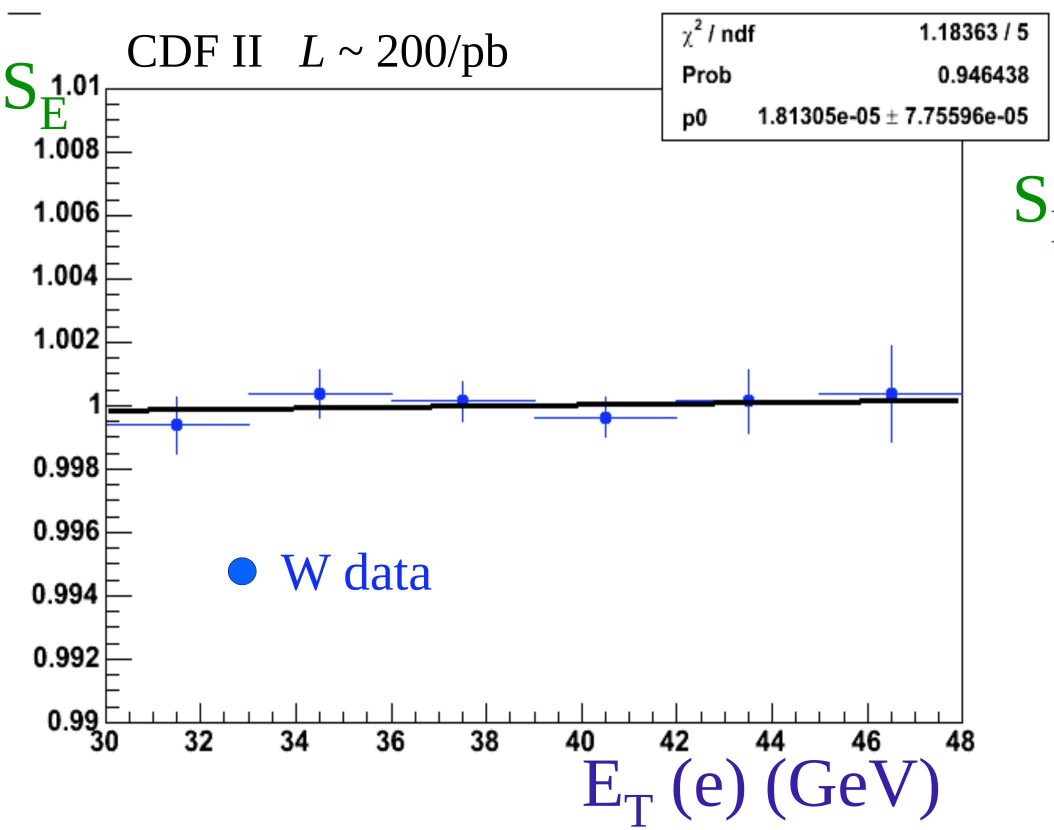


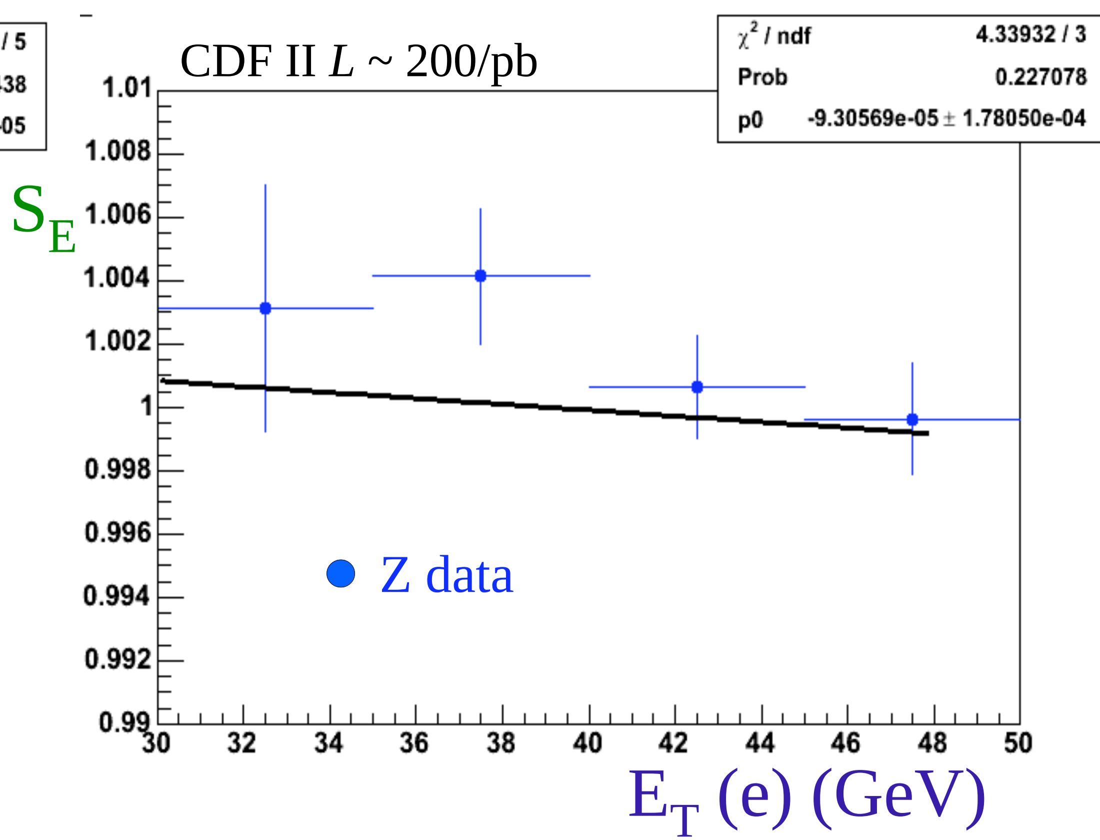


Measurement of EM Calorimeter Non-linearity

- Perform E/p fit-based calibration in bins of electron E_T
- Parameterize non-linear response as: $S_E = 1 + \zeta\,(E_T/\mathrm{GeV} - 39)$
- Tune on W and Z data: $\zeta = (6 \pm 7_{stat}) \times 10^{-5}$

  => $\Delta M_W = 23$ MeV

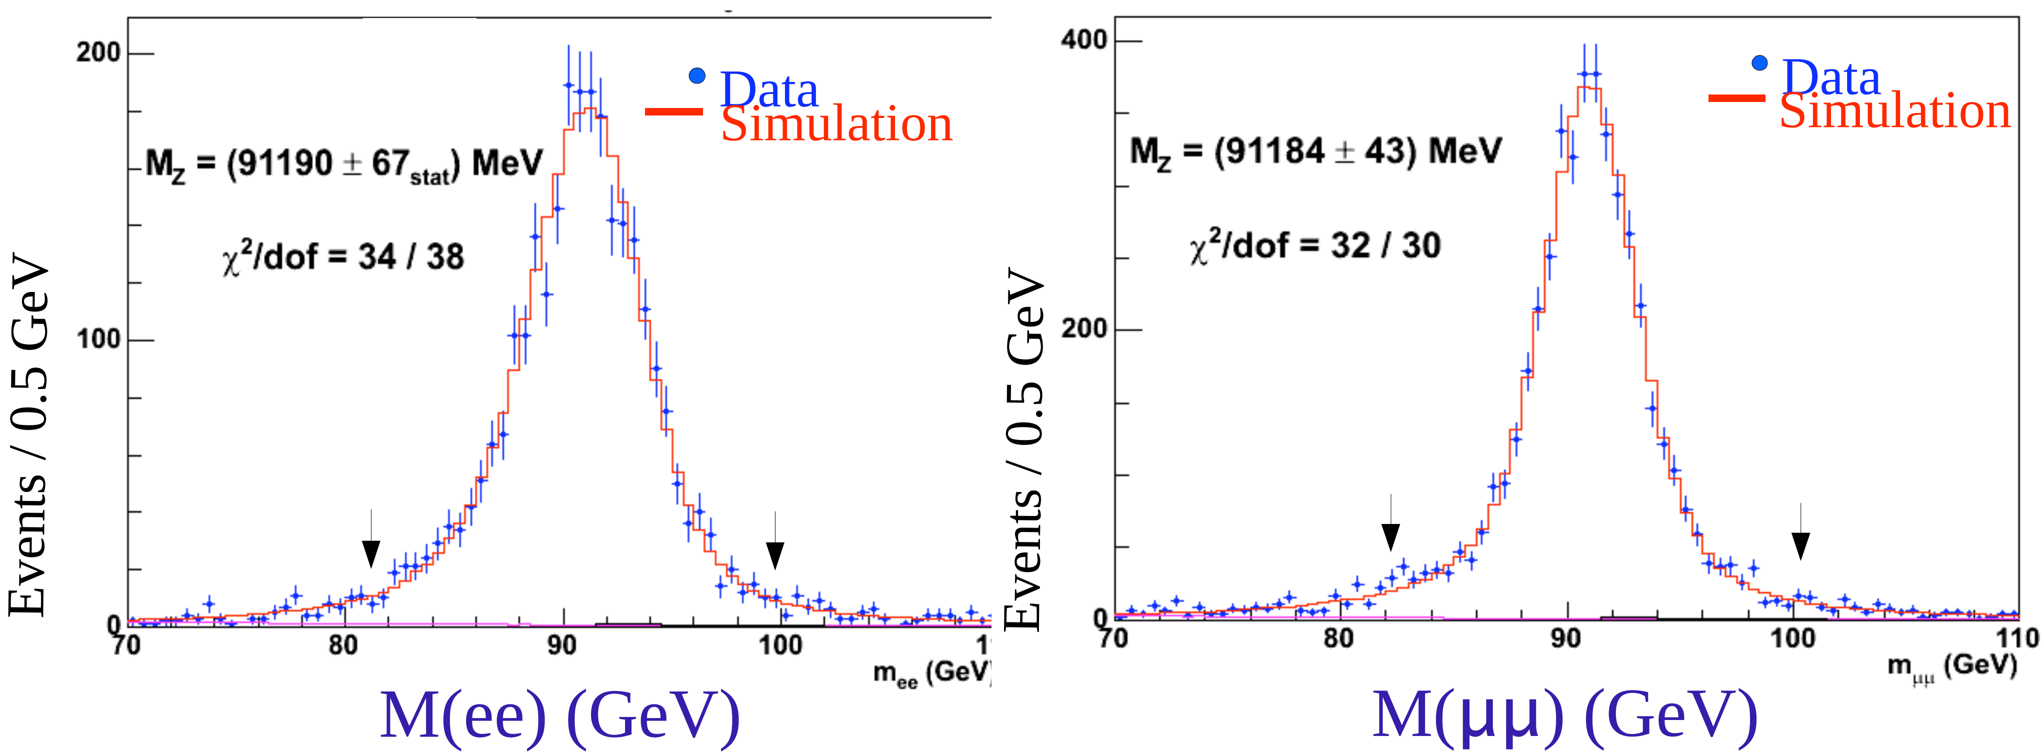




$Z \rightarrow ll$ Mass Cross-checks

- Z boson mass fits consistent with tracking and E/p-based calibrations
- This cross-check is statistics-limited, its validation power will keep improving with larger datasets

CDF II L ~ 200/pb

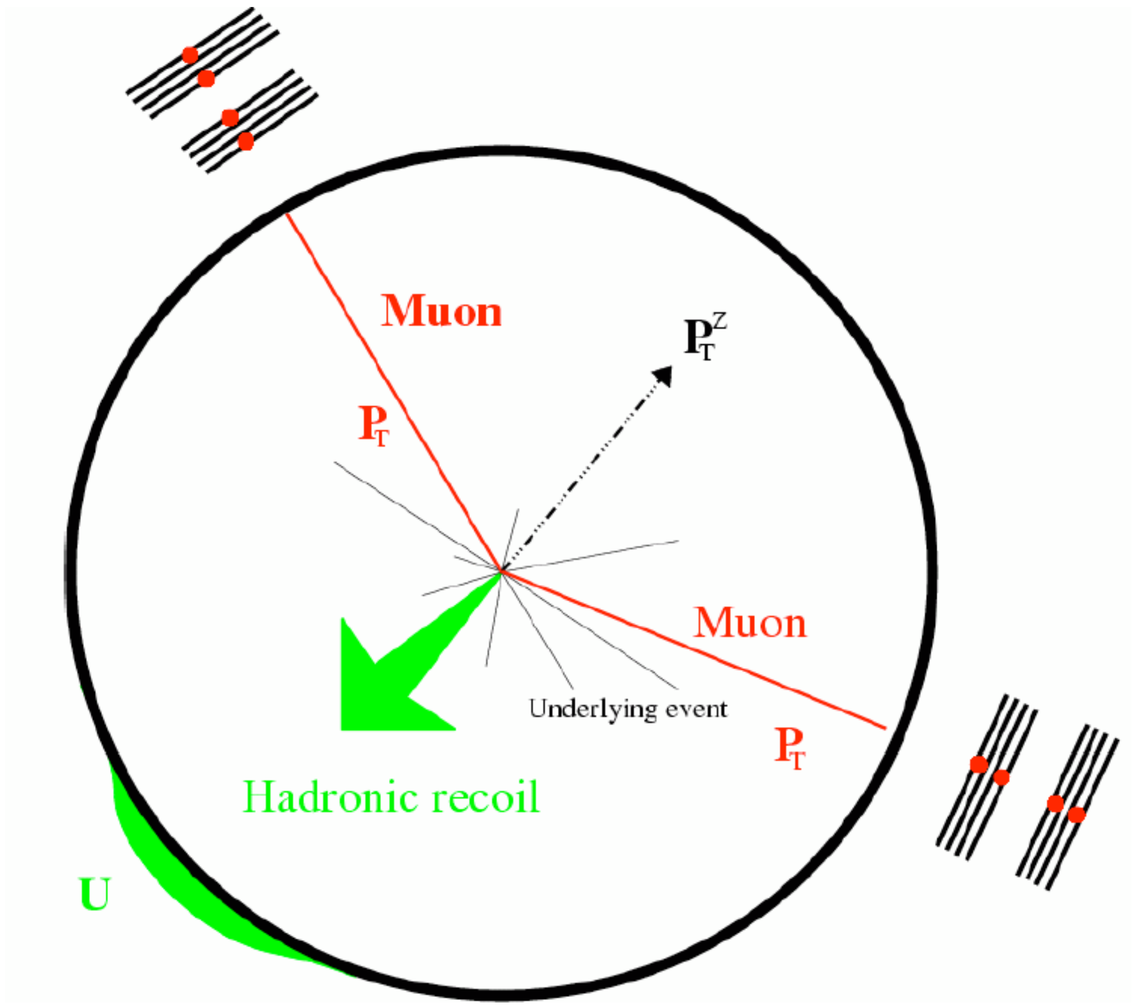


Hadronic Recoil Model

Constraining the Hadronic Recoil Model

Exploit similarity in production and decay of *W* and *Z* bosons

Detector response model for hadronic recoil tuned using p_T-balance in $Z \rightarrow ll$ events

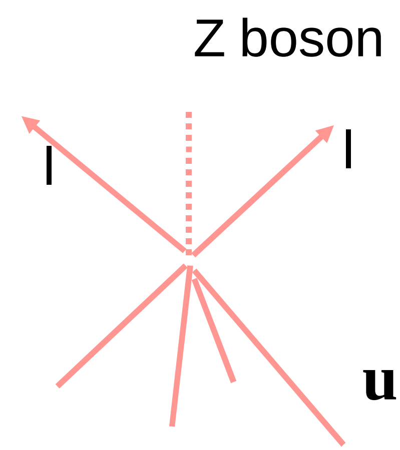


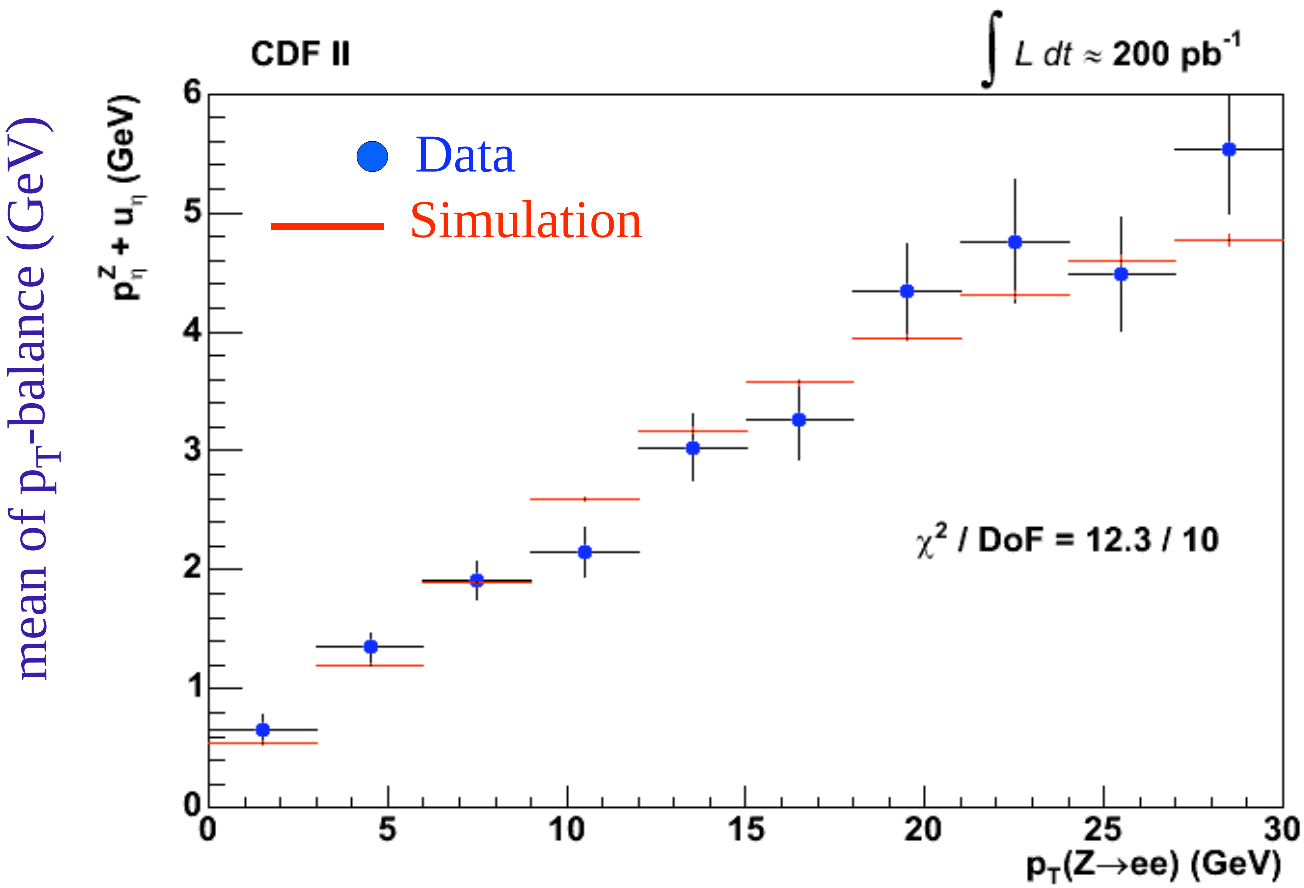
Transverse momentum of Hadronic recoil (***u***) calculated as 2-vector-sum over calorimeter towers

Tuning Recoil Response Model with *Z* events

Project the vector sum of $p_T(ll)$ and ***u*** on a set of orthogonal axes defined by lepton directions

Mean and rms of projections as a function of $p_T(ll)$ provide information hadronic model parameters





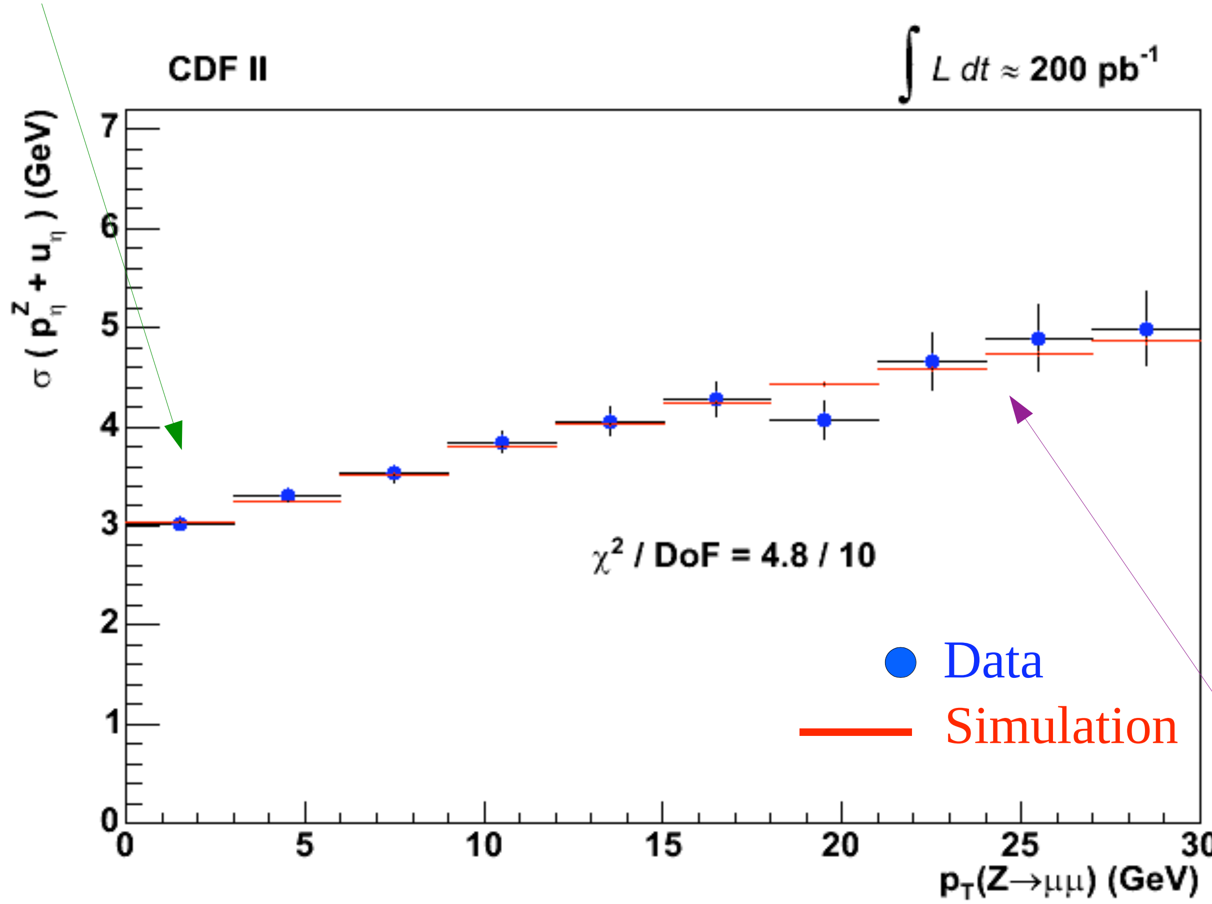
Hadronic model parameters tuned by minimizing χ^2 between data and simulation

$\Delta M_W = 9$ MeV

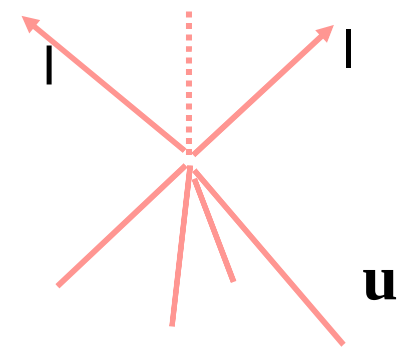
Tuning Recoil Resolution Model with *Z* events

At low $p_T(Z)$, p_T-balance constrains hadronic resolution due to underlying event

Resolution of p_T-balance (GeV)



Z boson

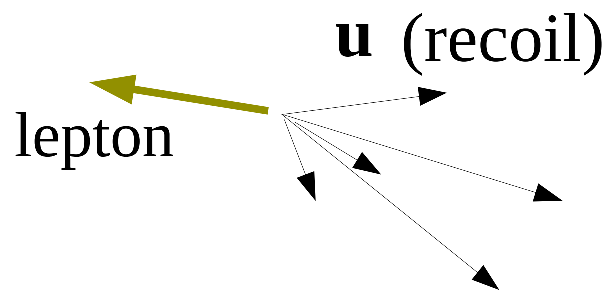


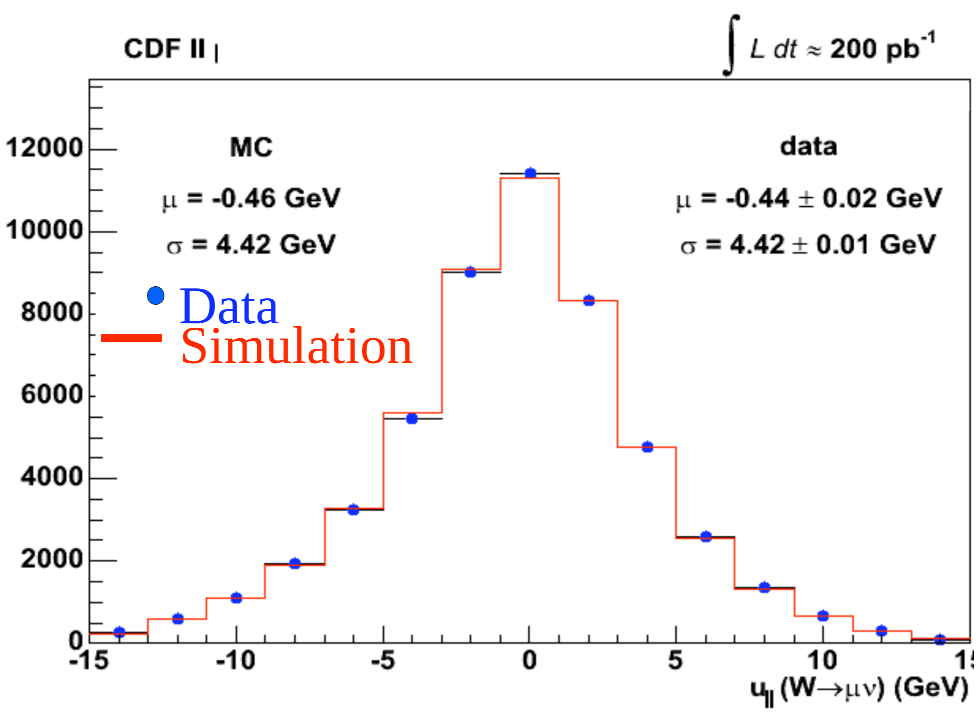
ΔM_W = 7 MeV

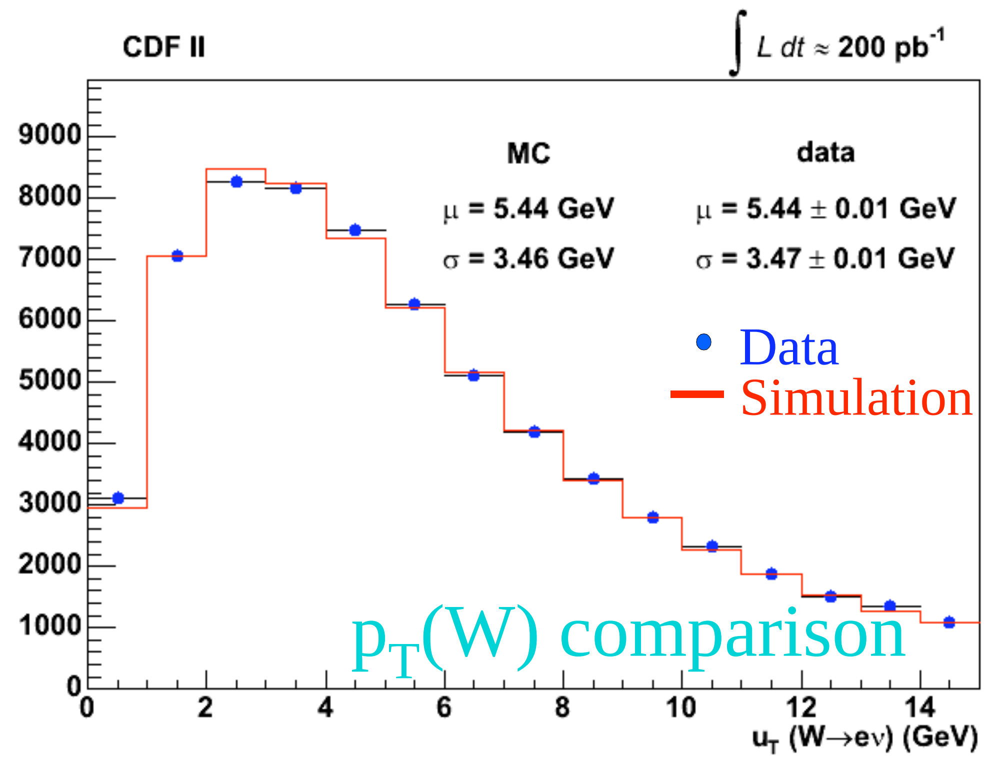
At high $p_T(Z)$, p_T-balance constrains jet resolution

Testing Hadronic Recoil Model with *W* events

Compare recoil distributions between simulation and data







Recoil projection (GeV) on lepton direction

W Mass Fits

W Transverse Mass Fits

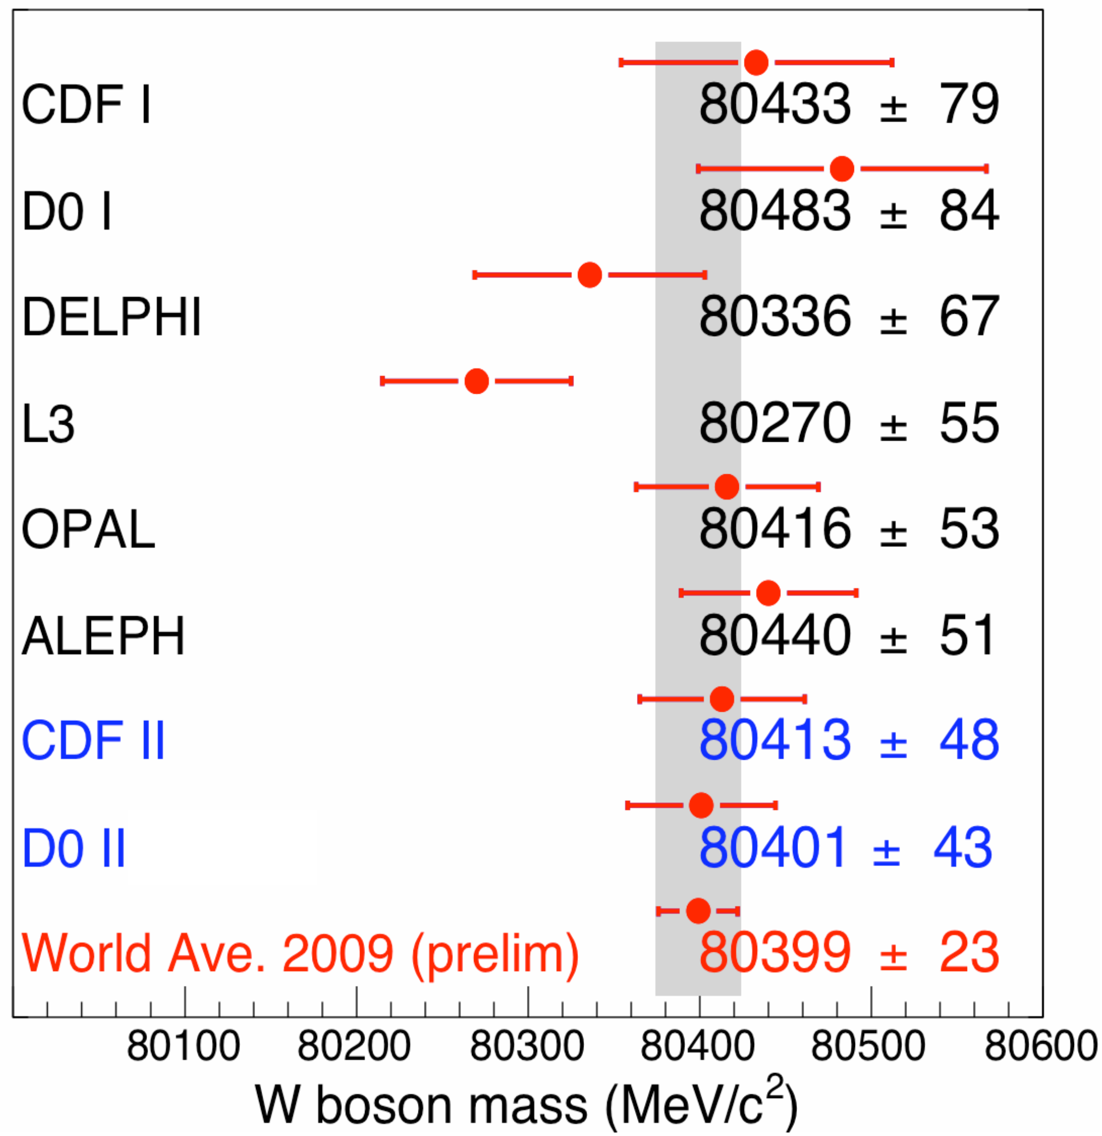
W Boson Mass Measurements

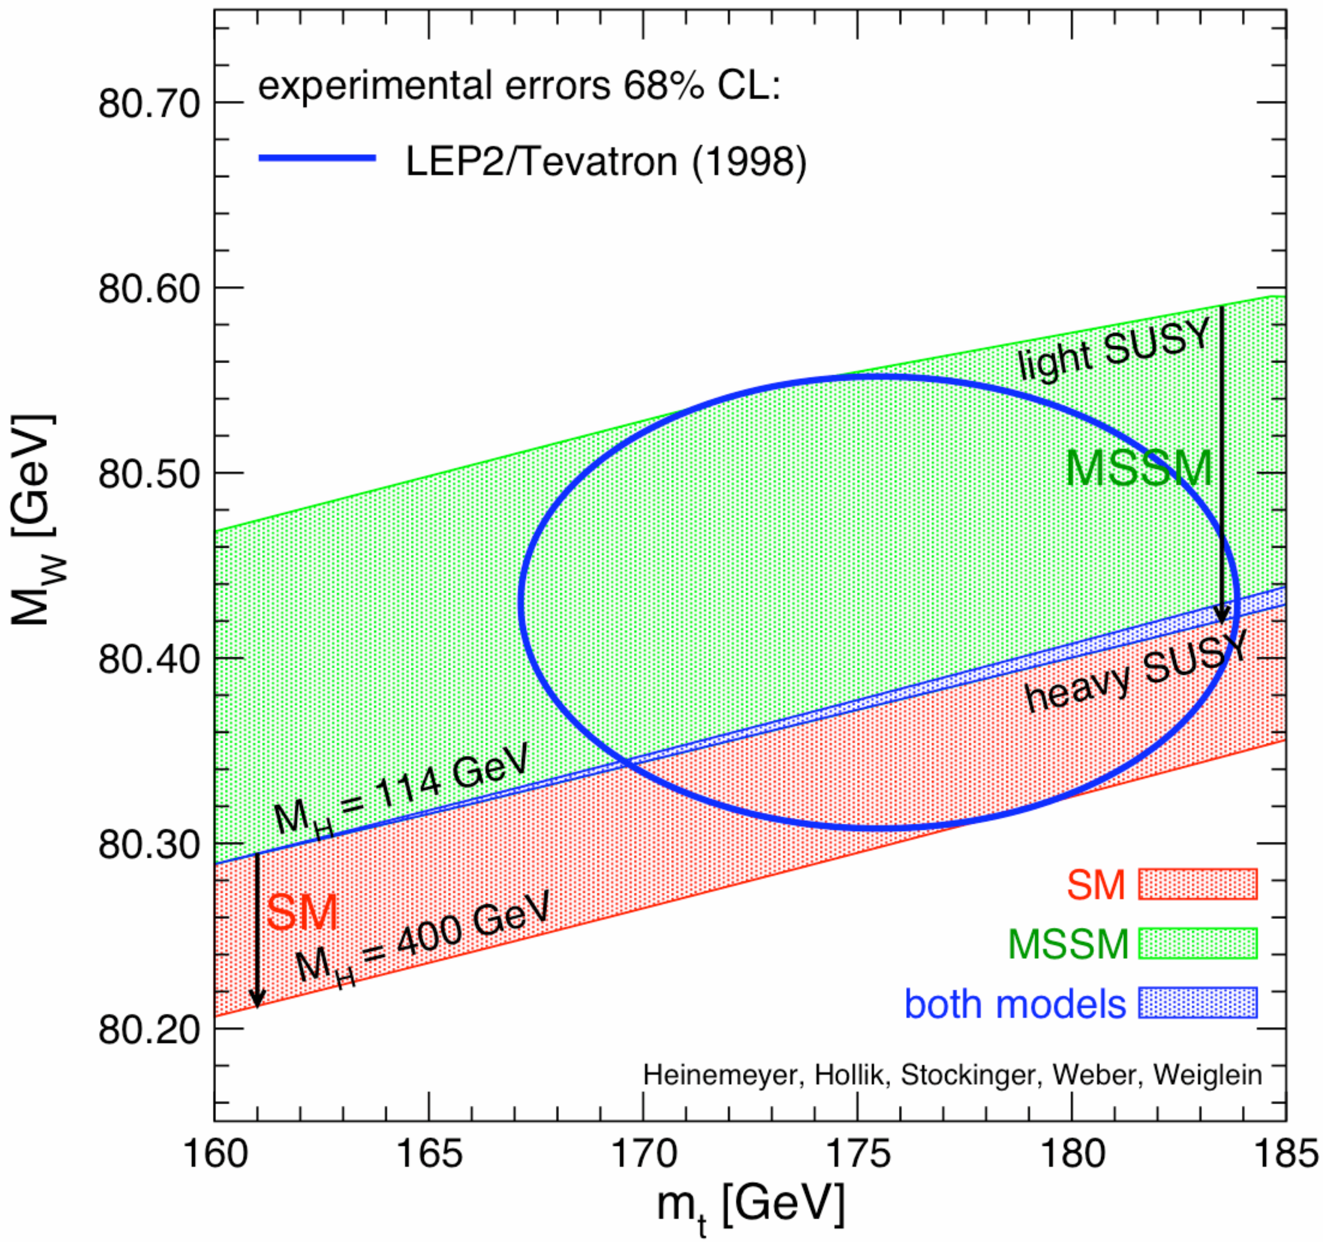
CDF: 200 pb^{-1}, electron and muon channels

D0: 1 fb^{-1}, electron channel

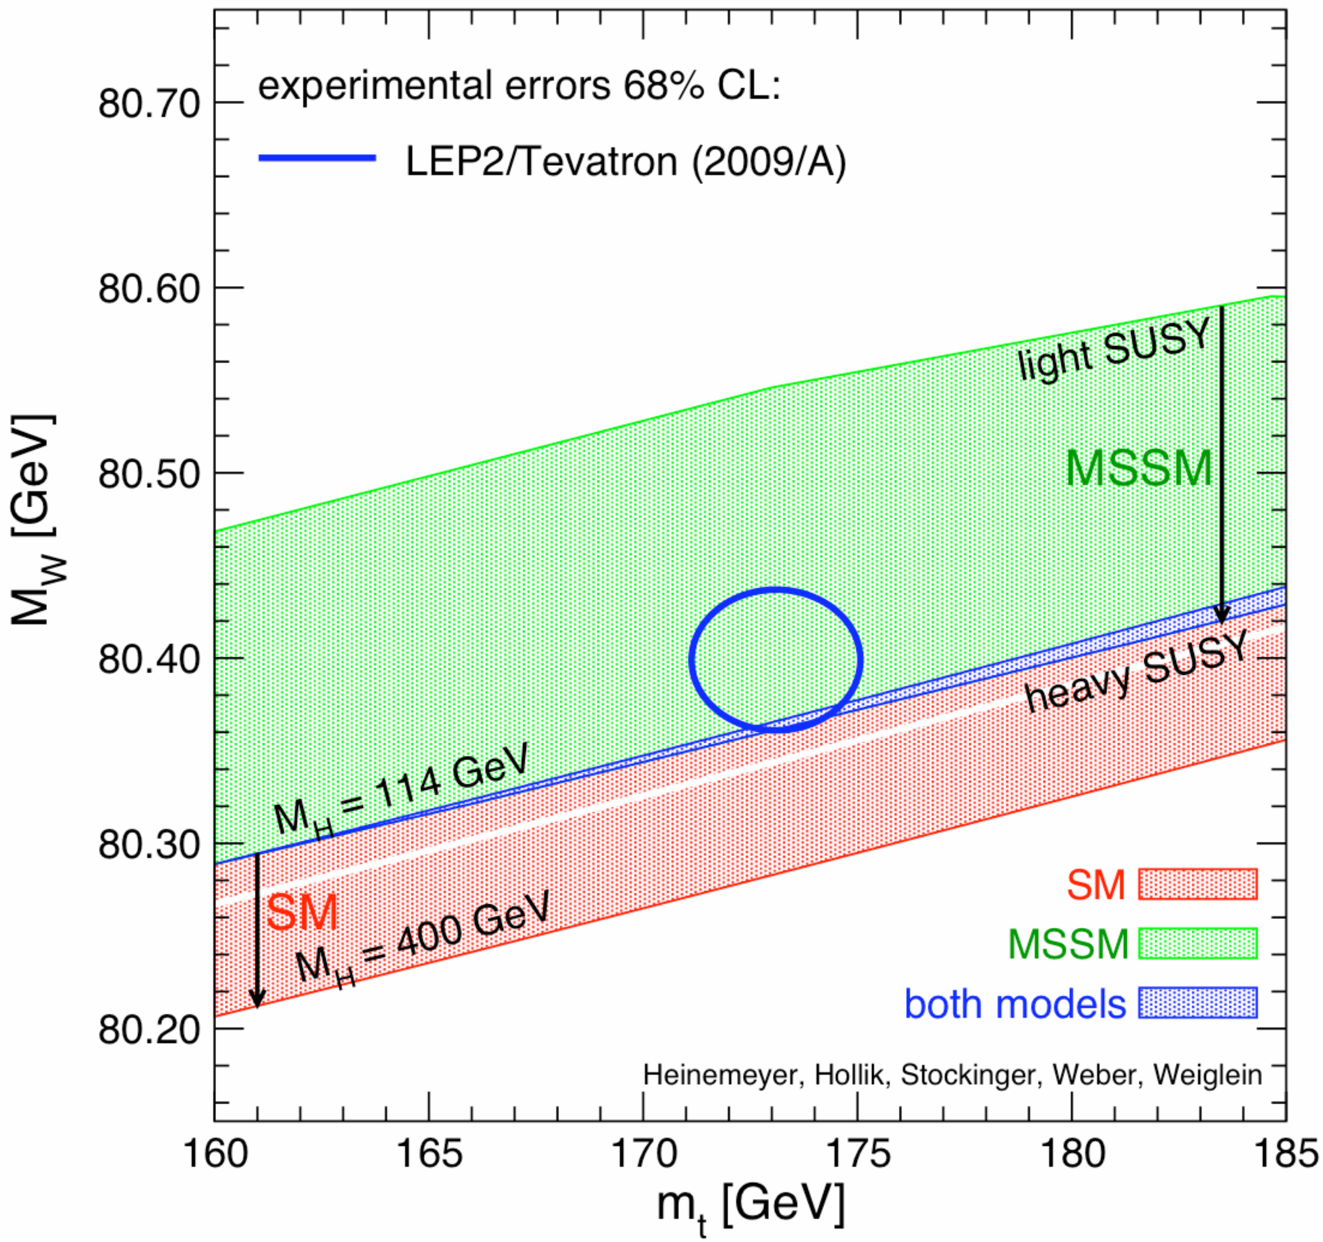


(D0 Run II: PRL 103:141801, 2009)
(CDF Run II: PRL 99:151801, 2007; PRD 77:112001, 2008)

Pre-Run 2 M_W *vs* M_{top}



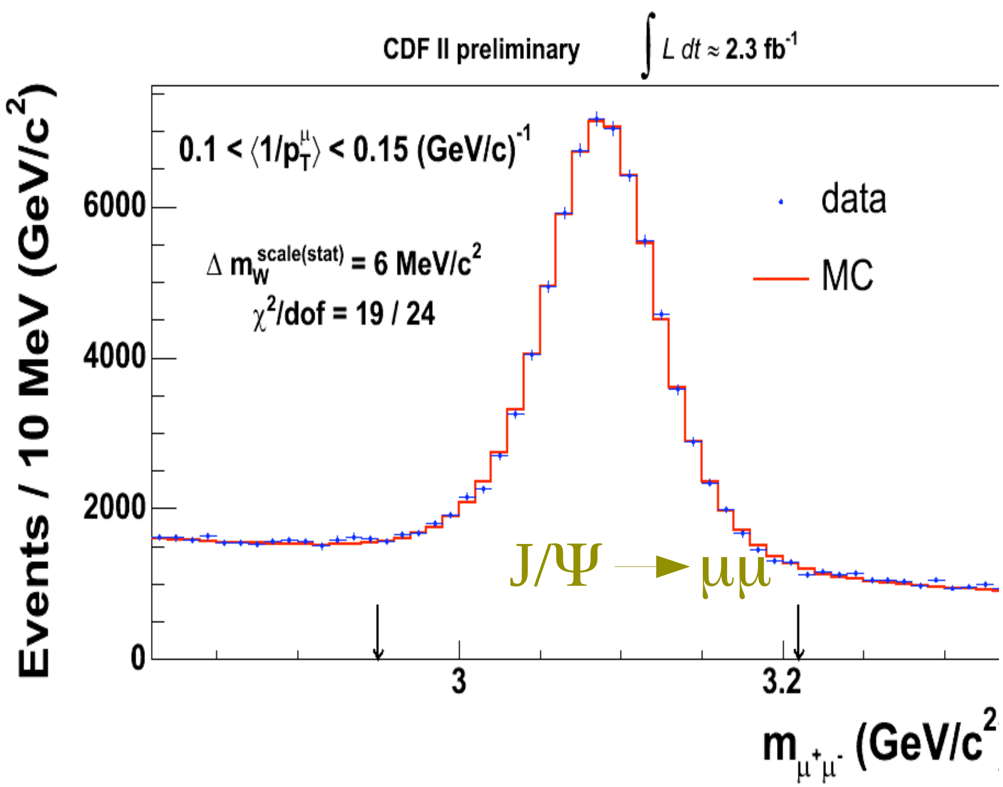
Post-Run 2 & LEPII M_W *vs* M_{top}

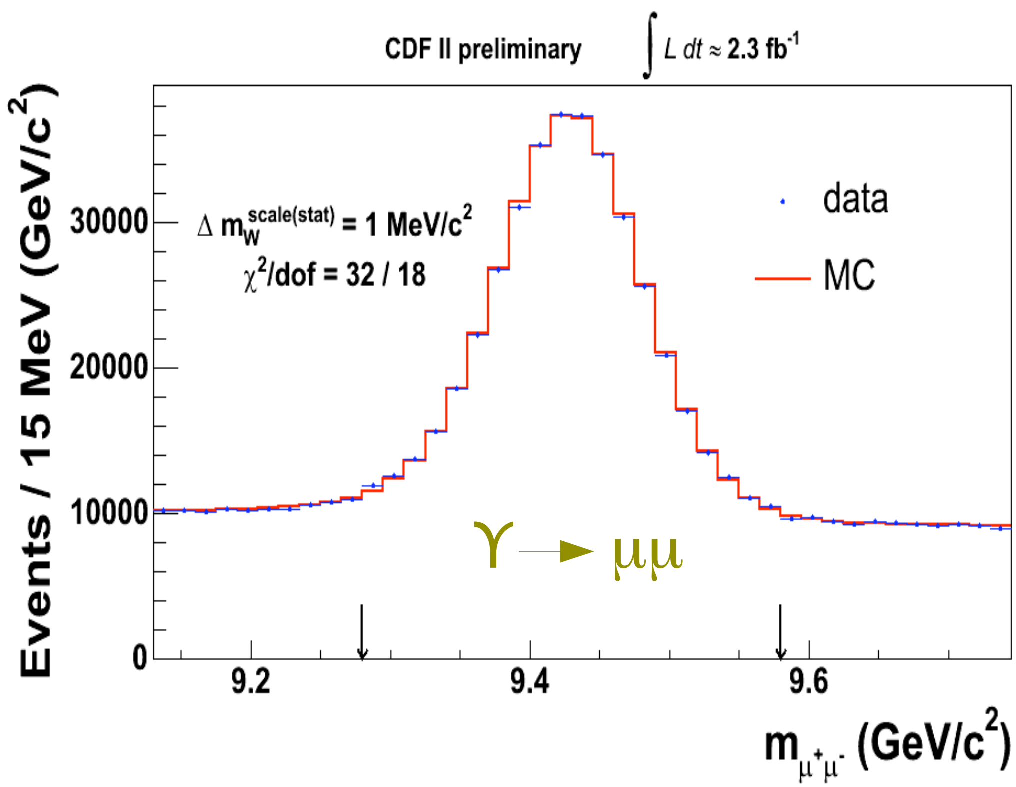


Preliminary Studies of 2.3 fb^{-1} Data from CDF

CDF analysis of 2.3 fb^{-1} of data is in progress, with the goal of measuring M_W with precision better than 25 MeV

Lepton resolutions as good as they were in 200 pb^{-1} sample





Summary

- The *W* boson mass is a very interesting parameter to measure with increasing precision
- CDF Run 2 W mass result with 200 pb^{-1} data:
  - M_W = 80413 ± 48 MeV
- D0 Run 2 W mass result with 1 fb^{-1} data:
  - M_W = 80401 ± 43 MeV
- Many systematics limited by statistics of control samples
  - CDF and D0 are both working on δM_W < 25 MeV measurements from ~ 2 fb^{-1} (CDF) and ~ 4 fb^{-1} (D0)
- Learning as we go: Tevatron → LHC may produce δM_W ~ 5-10 MeV

Combined Results

- Combined electrons (3 fits): M_W = 80477 ± 62 MeV, $P(\chi^2)$ = 49%
- Combined muons (3 fits): M_W = 80352 ± 60 MeV, $P(\chi^2)$ = 69%
- All combined (6 fits): M_W = 80413 ± 48 MeV, $P(\chi^2)$ = 44%

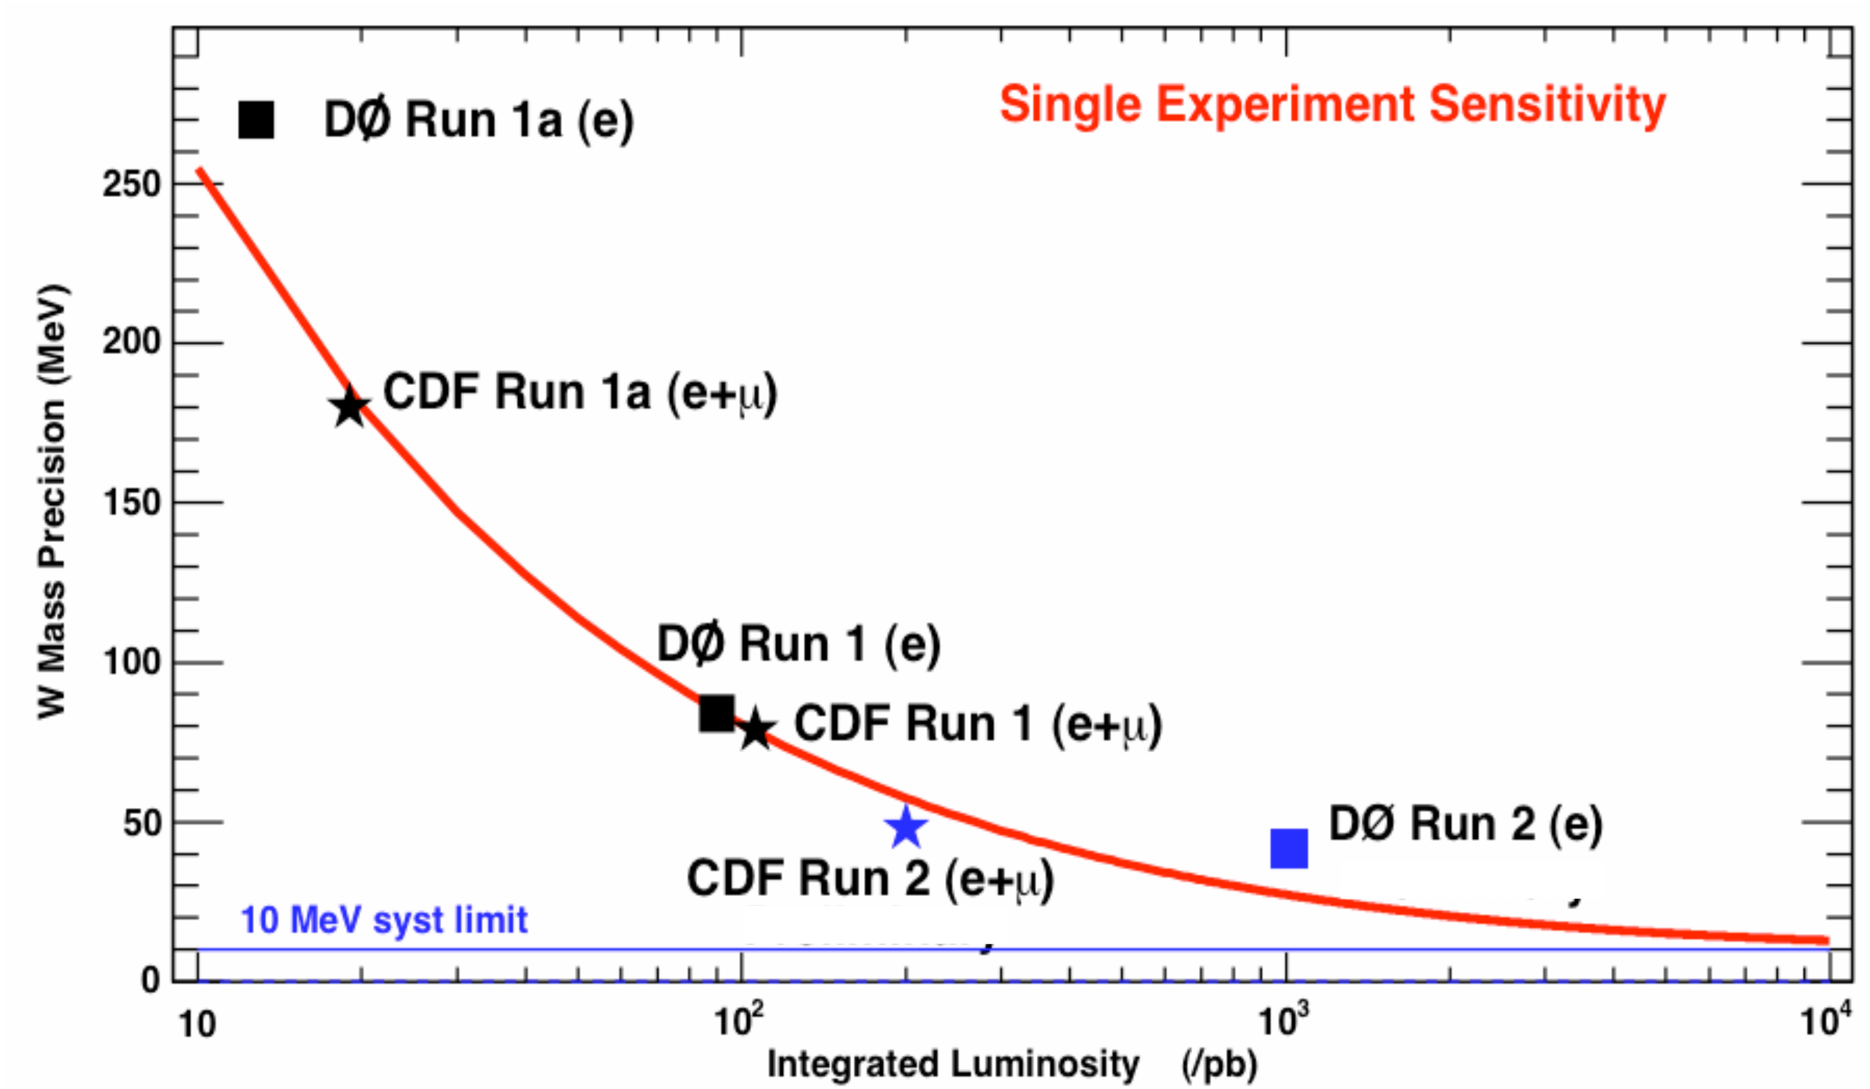
Improvement of M_W Uncertainty with Sample Statistics



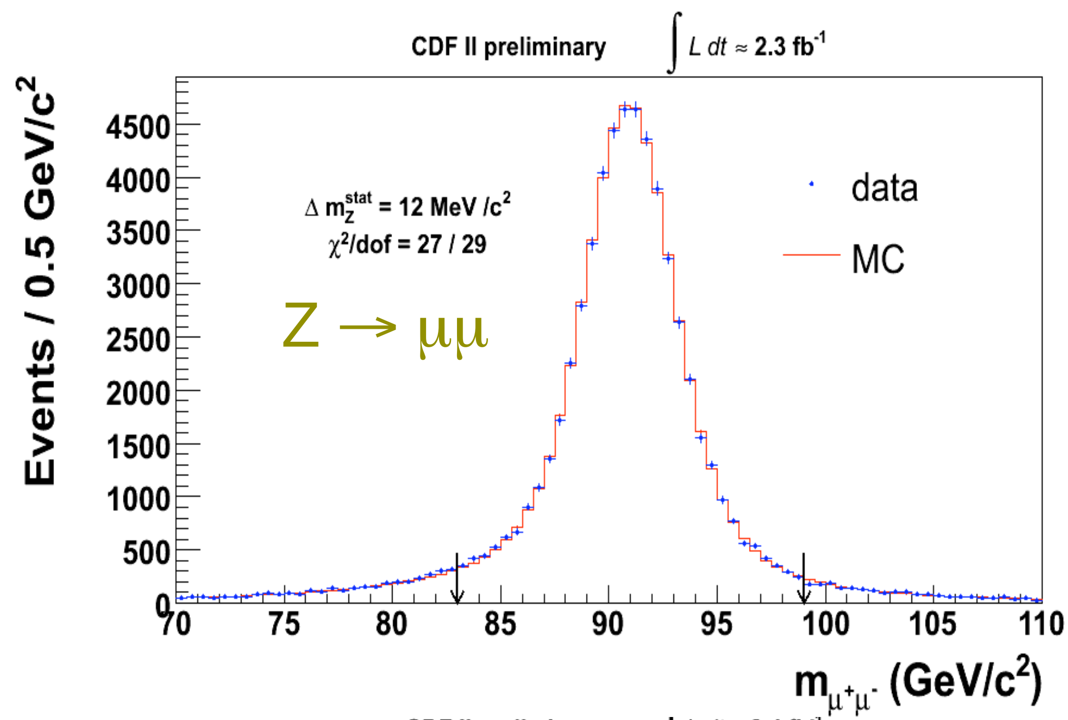
Next target: 15-20 MeV measurement of M_W from the Tevatron

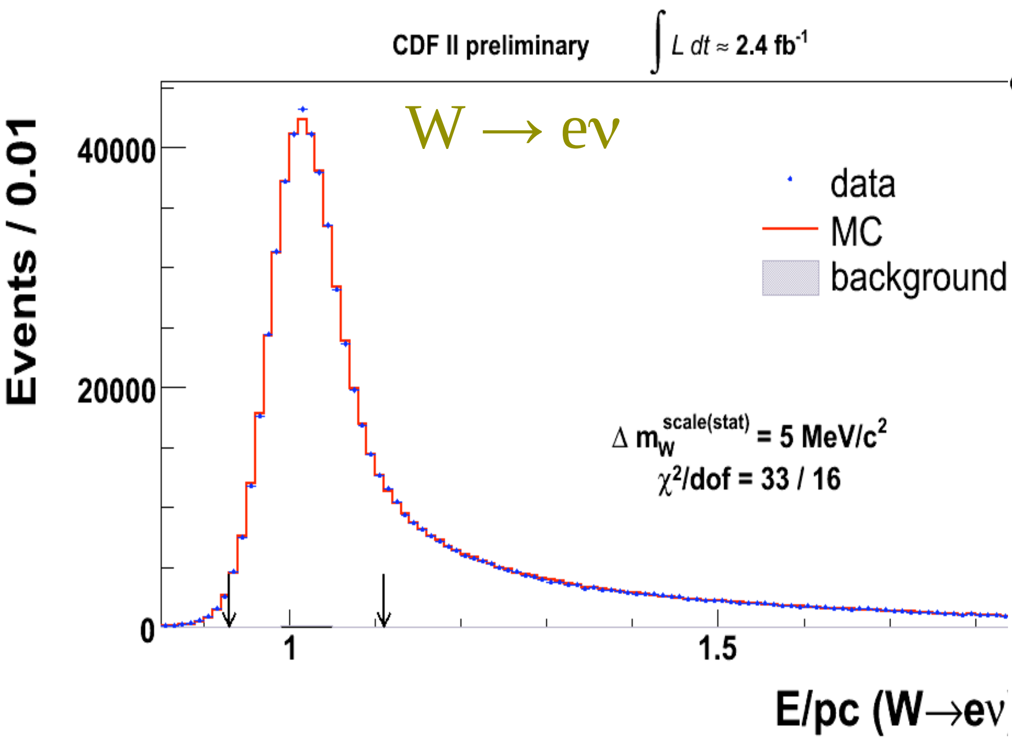
Preliminary Studies of 2.3 fb^{-1} Data

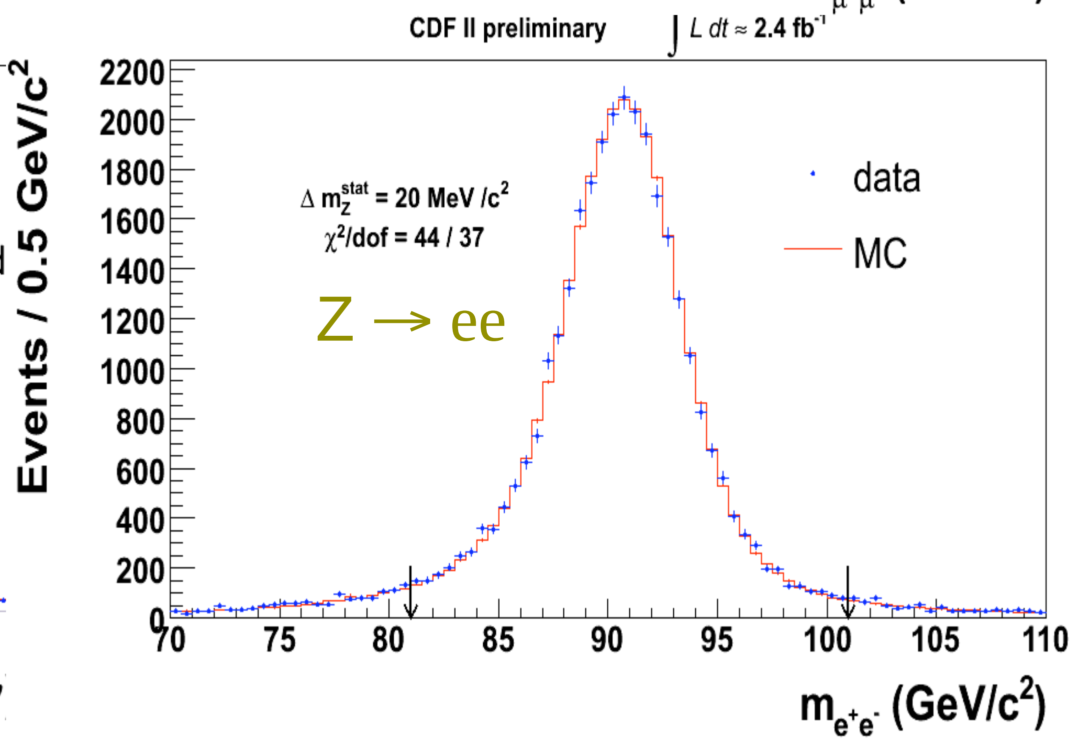
Statistical errors on all lepton calibration fits have scaled with statistics

Detector and data quality maintained over time

detailed calibrations in progress

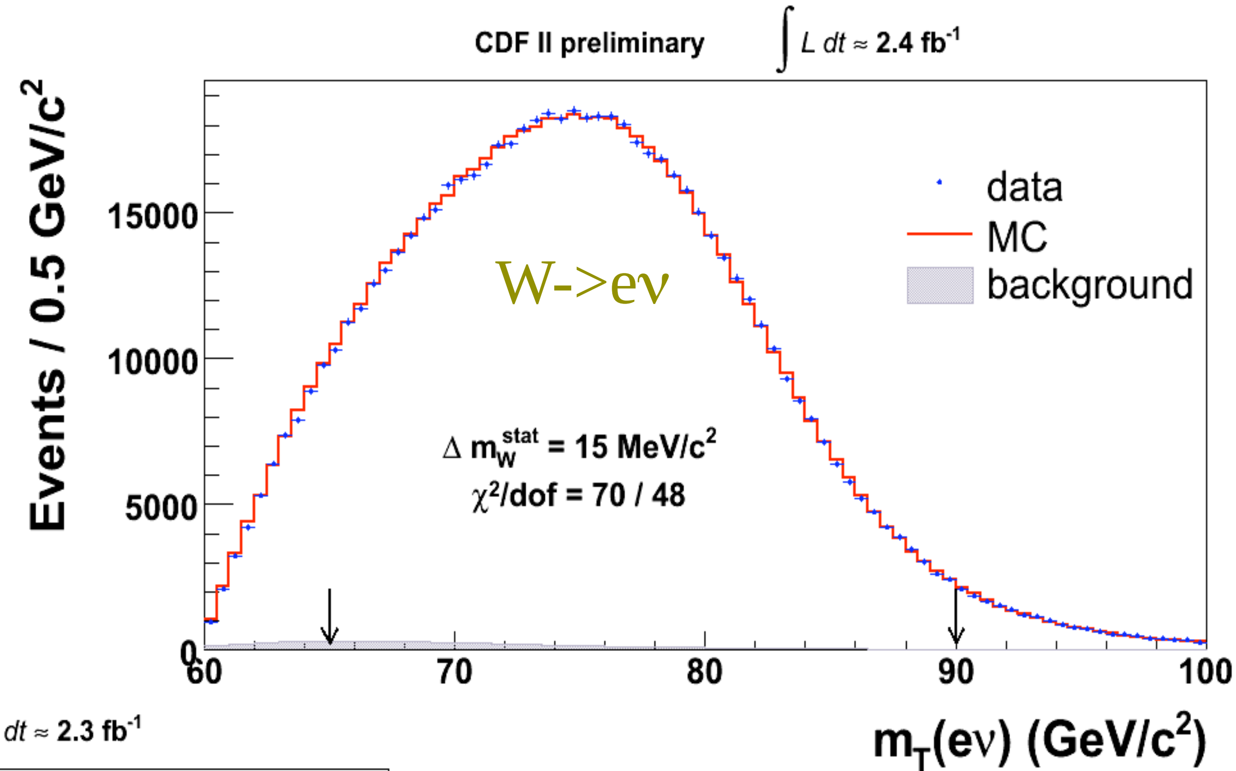


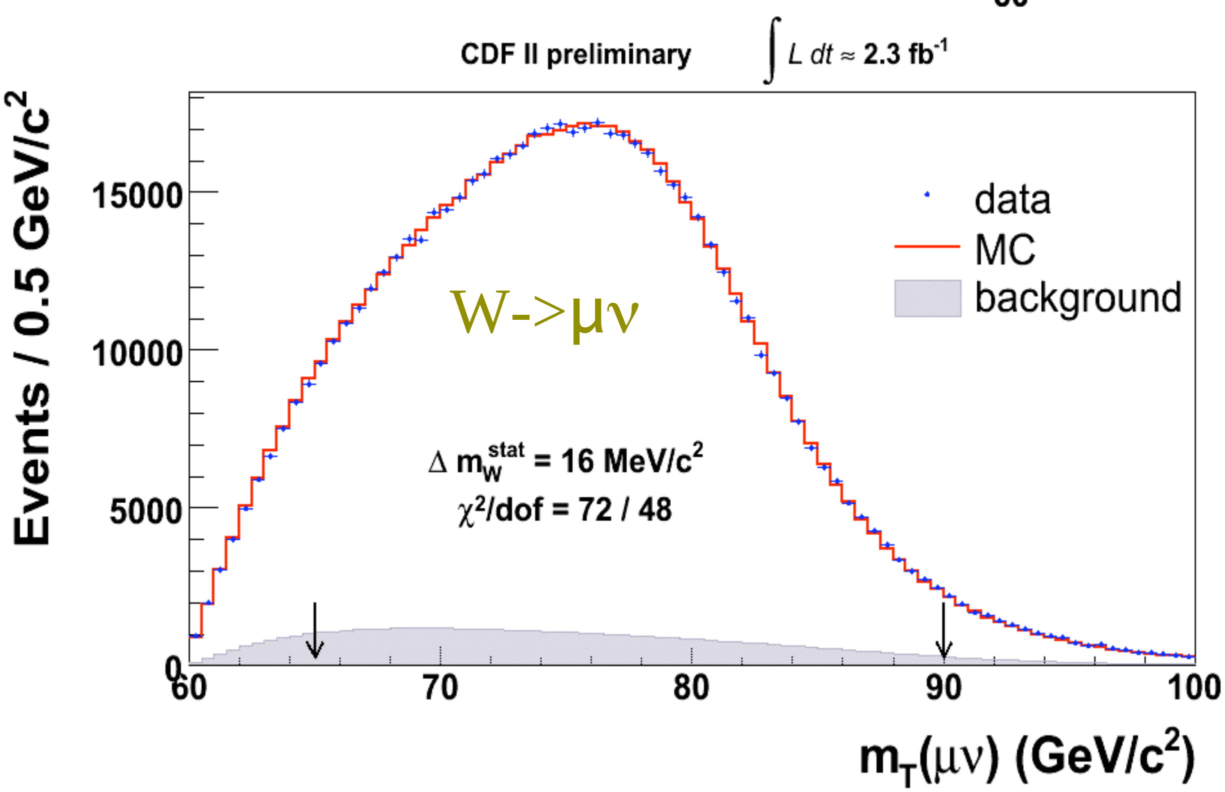




Preliminary Studies of 2.3 fb^{-1} Data

Recoil resolution not significantly degraded at higher instantaneous luminosity





statistical errors on transverse mass fits are scaling with statistics

M_W Measurement at LHC

- Very high statistics samples of W and Z bosons
  - 10 fb^{-1} at 14 TeV: 40 million W boson and 4 million Z boson candidates per decay channel per experiment
- Statistical uncertainty on W mass fit ~ 2 MeV
- Calibrating lepton energy response using the Z → *ll* mass resonance, best-case scenario of statistical limit ~ 5 MeV precision on calibrations
- Calibration of the hadronic calorimeter based on transverse momentum balance in Z → *ll* events also ~ 2 MeV statistical limit
- Total uncertainty on M_W ~ 5 MeV if Z → *ll* data can measure all the W boson systematics

M_W Measurement at LHC

- Can the Z → *ll* data constrain all the relevant W boson systematics?
- Can we add other constraints from other mass resonances and tracking detectors ?

- With every increase in statistics of the data samples, we climb a new learning curve on the systematic effects
  - Improved calculations of QED radiative corrections available
  - Better understanding of parton distributions from global fitting groups (CTEQ, MSTW, Giele *et al*)

- large sample statistics at the LHC imply the potential is there for 5-10 MeV precision on M_W

M_W Measurement at LHC

- Can the Z → *ll* data constrain all the relevant W boson systematics?
- Production and decay dynamics are slightly different
  - Different quark parton distribution functions
  - Non-perturbative (e.g. charm mass effects in *cs* → W) effects
  - QCD effects on polarization of W *vs* Z affects decay kinematics
- Lepton energies different by ~10% in W *vs* Z events
- Presence of second lepton influences the Z boson event relative to W
- Reconstructed kinematic quantity different (invariant vs transverse mass)
- Subtle differences in QED radiative corrections
- ....
- .... (A.V. Kotwal and J. Stark, Ann. Rev. Nucl. Part. Sci., vol. 58, Nov 2008)
