Abstract. In this talk, I review the potential connection of neutrinos to the Physics of the Early Universe, in particular the role of (sterile) neutrinos to leptogenesis/baryogenesis and the dark sector of the Universe. The possibility of CPT Violation among active neutrinos at early times and its role in leptogenesis/baryogenesis without sterile neutrinos is also touched upon.

1. Introduction and motivation
Neutrinos are fascinating particles, still full of mysteries and surprises. Not long after the end of this meeting, we have heard the claims from OPERA Collaboration [1] on the measurements of the arrival time of neutrinos, indicating superluminal propagation. Although this result may not be actually due to fundamental (Lorentz violating or modifying) physics but rather due to measurement uncertainties, given the complicated nature of the measurement and the many potential systematic errors that may have entered (including the particle decays that can produce the final signal, which undoubtedly introduce statistical uncertainties in the arrival times), nevertheless neutrinos made big headlines all over the world once again, and opened up interesting avenues for research, given that superluminal propagation, that characterises already existing theoretical models, may not be incompatible with causality. In this talk I will not discuss such issues, however I will touch upon a different rôle of neutrinos (assumed throughout to respect Lorentz Invariant kinematics, thus being subluminal, almost light-like due to their tiny masses) that relates to the Physics of the Early Universe. In particular, one of the most important questions of fundamental Physics that is still unanswered today, which pertains to our very existence, is the reason for the observed baryon asymmetry in the Universe, or why the Universe is made up mostly of matter. According to the Big bang theory, matter and antimatter have been created at equal amounts in the Early universe. The observed charge-parity (CP) violation in particle physics [2], prompted A. Sakharov [3] to conjecture that non-equilibrium Physics in the Early Universe produce Baryon number (B), charge (C) and charge-parity (CP) violating, but CPT conserving, interactions/decays of anti-particles in the early universe, resulting in the observed baryon-antibaryon ($n_B - n_{\overline{B}}$) asymmetry. In fact there are two types of non-equilibrium processes in the Early universe that could produce this asymmetry: the first type concerns processes generating asymmetries between leptons and antileptons, while the second produce asymmetries between baryons and antibaryons. The almost 100% observed asymmetry today, is estimated in the Big-Bang theory [4] to be of order:

$$\Delta n(T \sim 1 \text{ GeV}) = \frac{n_B - n_{\overline{B}}}{n_B + n_{\overline{B}}} \sim \frac{n_B - n_{\overline{B}}}{s} = (8.4 - 8.9) \times 10^{-11}$$

at the early stages of the expansion, e.g. for times $t < 10^{-6} \text{ s}$ and temperatures $T > 1 \text{ GeV}$. In the above formula $n_B$ ($n_{\overline{B}}$) denotes the (anti) baryon density in the Universe, and $s$ is the entropy density. Unfortunately, the observed CP violation within the Standard Model (SM) of Particle Physics (found to be of order $\epsilon = O(10^{-2})$ in the neutral Kaon experiments [2])
cannot reproduce $^1$. Let us review why $^3$. Although classically, the baryon (B) and Lepton ($L_{e,\mu,\tau}$) numbers are conserved in the SM, at a quantum level anomalies in general break these symmetries. The anomalies are associated with the non-conserved currents corresponding to the above classical symmetries in the combination $\partial^\mu J^B_\mu = \partial^\mu J^L_\mu = \sum_{f} \frac{N_f}{2} \mathrm{Tr} F_{\mu \nu} F^{\mu \nu} + U(1) - \text{parts}$, with $N_f$ the flavour number. Since the allowed processes in the SM are those which entail a change of B by multiples of 3, that is bosons $\leftrightarrow$ bosons + 9 quarks + 3 leptons, there is a conservation law for the three combinations $L_i - B/3, \ i = e, \mu, \tau$. However the observed neutrino oscillations among flavours, imply that only one global number may be conserved in the SM, the combination $B - L$, where $L = \sum L_i$ is the total Lepton number. In fact if neutrinos are Majorana, the $L$ would be itself violated, and hence there would be no conserved numbers at all! With this in mind one may evaluate the rate of B violation in the SM $^3$: $\Gamma \sim (\alpha_W T)^4 (M_{\text{sph}}/T_\text{sph})^7 \exp(-\frac{M_{\text{sph}}}{T_\text{sph}})$, if $T \leq M_{\text{sph}}$, while $\Gamma \sim (\alpha_W T)^4 \alpha_W \log(1/\alpha_W)$ if $T \geq M_{\text{sph}}$, with $\alpha_W$ the fine structure constant of the electroweak SU(2) symmetry, and $M_{\text{sph}}$ is the sphaleron mass scale, in particular $M_{\text{sph}}/\alpha_W$ is the height of the energy barrier separating SU(2) vacua with different topologies. Thermal equilibrium (i.e. $\Gamma > H$ (Hubble rate)) for B non conserving processes occurs only for $^5 T_{\text{sph}}(m_h) < T < \alpha_W^{-1} M_P \sim 10^{12}$ GeV; with the Higgs mass $m_h$ assumed in the range (in agreement with current LHC exclusion data) $m_h \in [100, 300]$ GeV , one has $T_{\text{sph}} \in [130, 190]$ GeV. Baryon Asymmetry in the Universe (BAU) could be produced only when the sphaleron interactions freeze out, that is for temperatures $T \simeq T_{\text{sph}}$. One should compute, within the SM, the CP violation effects at such a regime of parameters and temperature, using the Cabbibo-Kobayashi-Maskawa (CKM) matrix. The lowest SM CP violating structures are encoded in the quantity $\delta_{CP} = \sin(\theta_{12})\sin(\theta_{23})\sin(\theta_{13})\sin\delta_{CP}(m_1^2 - m_2^2)(m_1^2 - m_3^2)(m_2^2 - m_3^2)(m_2^2 - m_3^2)(m_3^2 - m_2^2)$, where $\delta_{CP} = D/T_{12}^2$ is the Kobayashi-Maskawa CP Violating phase, and $D$ is the Jarlskog determinant, related to the appropriate quark mass matrices as $^6$: $D = \mathrm{Tr}(M_u^2 M_d^2)$. Computing the parameter $\delta_{CP}$ at $T \simeq T_{\text{sph}}$ in the above range, one obtains $\delta_{CP} \sim 10^{-20}$ which yields a baryon asymmetry ten orders of magnitude smaller than the observed one $^1$. Hence the SM CP violation cannot be the source for the observed BAU. There are several ideas that go beyond the SM (e.g. GUT models, Supersymmetry, extra dimensional models etc.) in an attempt to find extra sources for CP violation that could generate the observed BAU. Since massive neutrinos (as evidenced by the observed flavour oscillations) constitute the simplest extension of SM, it is reasonable to seek for a possible rôle of neutrinos in providing us with the required amount of CP violation to explain the observed BAU. Right-handed supermassive (Majorana) neutrinos (sterile) may do the job and more than that. Namely, as we shall discuss below, such extensions of the SM can provide sufficient extra sources for CP Violation to explain the Origin of Universe’s matter-antimatter asymmetry due to the relevant neutrino masses, without the need for Supersymmetry or extra dimensions. Moreover, as we shall discuss below, such models can also incorporate a natural Dark Matter candidate (the lightest of the sterile neutrinos), in agreement with observations $^6$.

2. **Sterile neutrino SM extensions and Leptogenesis/Baryogenesis**

Several authors have suggested the use of right-handed, supermassive sterile neutrinos as possible extensions beyond the SM, with relevance to the physics of the Early universe. In this talk, I concentrate on the simplest of such extensions, a non supersymmetric SM augmented with N generations of right-handed massive, with masses $M_i$, Majorana fermions, termed $\nu MSM$, a terminology I will use from now on: $^6 7$ $L_\nu MSM = L_\nu SM + \bar{N}_I \gamma^\mu \partial_\mu N_I - F_{\alpha I} \bar{L}_ \nu N_I \phi - \frac{M}{\sqrt{2}} \bar{N}_I N_I + \text{h.c.}$, where the suffix SM denotes the SM part of the Lagrangian, $N_I, \ I = 1, \ldots N$ denote the Majorana sterile neutrinos, the superscript $c$ denotes charge conjugate, and $L_{\alpha}, \ \alpha = c, \mu, \tau$ are the leptons. The field $\phi$ is the SU(2) dual of the Higgs scalar $\phi = 1_{\alpha \dot{\phi}}$, $i,j$ SU(2) indices, while $F_{\alpha I}$ are matrix valued Yukawa couplings involving majorana phases and mixing angles $^6 7$. The model with N=1 sterile neutrino is excluded by the current data $^8$, while the models with $N=2,3$ work well in reproducing BAU and are consistent with the current experimental
when SM gauge interactions are taken into account.

elaborate treatments is that the conventional Boltzmann equations for Lepton asymmetry give pretty good results

Kadanoff-Baym (KB) equations based on Green’s functions, not on densities [12]. The conclusion of such more

Since the Leptogenesis processes are out of (thermal) equilibrium, the correct way to incorporate the quantum effects would be to consider the non-equilibrium field theory Schwinger-Keldysh formalism and the Kadanoff-Baym (KB) equations based on Green’s functions, not on densities [12]. The conclusion of such more elaborate treatments is that the conventional Boltzmann equations for Lepton asymmetry give pretty good results when SM gauge interactions are taken into account.

1 Although the Boltzmann equations are classical equations for the time evolution of phase space distribution functions f(p,x,t), however the collision terms C[p] on the r.h.s. are quantum effects involving loop corrected cross sections. Since the Leptogenesis processes are out of (thermal) equilibrium, the correct way to incorporate the quantum effects would be to consider the non-equilibrium field theory Schwinger-Keldysh formalism and the Kadanoff-Baym (KB) equations based on Green’s functions, not on densities [12]. The conclusion of such more elaborate treatments is that the conventional Boltzmann equations for Lepton asymmetry give pretty good results when SM gauge interactions are taken into account.
oscillations of the two degenerate in mass right-handed fermions, may be realised. The Heavy
enhances CP violation. In such a case, the scenario of [10], on Baryogenesis through coherent
oscillations of the two heavy Majorana neutrinos are degenerate in mass, say $N_2$. In such a case, in order to guarantee the smallness of the light neutrino masses, the relevant
Yukawa couplings should be of order [6]: $F \sim M_3 M_2 \sim m_ν M_W \sim 10^{-13}$, with $M_1 \sim M_W$. There is an enhancement of the
induced CP violation in this case (due to the lower two graphs in the left picture of fig. 1). This
enhanced CP violation due to the existence of degenerate in mass quantum states is familiar
from the case of neutral Kaons [2]. Such models yield enhanced CP violation if the
branching ratio of order $I_{22} \sim 4 \times 10^{-4}$ for the above range of $M_1$. One lepton number ($τ$) is resonantly produced by the
out-of-equilibrium decays of $N_1$. To avoid excess of L$+$ - number violation, the decay rates of
$N_{2,3}$ are suppressed. The predicted BAU in such a class of models (termed resonant Leptogenesis
for obvious reasons) can be naturally made to agree with the observed one, as following from a
calculation of the thermal relic abundances of the $N_1$ neutrino, by means of solving the pertinent
Boltzmann equations (cf. right picture in fig. 1). Leptogenesis is possible for these models if $M_I$
is in the range $M_I \in \{M_W - \text{TeV}\}$. The predicted Lepton-number violating process $μ \to e γ$ has
branching ratio of order $B(μ \to e γ) = 6 \times 10^{-4} a^2 b^2 v^4 / M_1^4$, where $a, b$ are parameters entering
the appropriate Yukawa coupling matrix of the model [13]. For natural values $a, b \sim 10^{-3}$, required
by Leptogenesis, one has $B(μ \to e γ) \leq 1.2 \times 10^{-11}$ for the above range of $M_I$. This
is just one order of magnitude larger than the current sensitivity of the MEG Experiment [15]
to the Branching ratios for $μ^+ \to e^+ γ$, $B(μ^+ \to e^+ + γ) \leq 2.4 \times 10^{-12}$. In [13] there were also
examined possible effects of such degenerate models in linear $e^+e^−$ colliders, where one should
study the production of electroweak scale $N_{2,3}$ via their decays to $e, μ$ but not $τ$.

(II) Case where $M_I < M_W$: consider, for instance, the case where $M_I = O(1)$ GeV. In such a case, in order to guarantee the smallness of the light neutrino masses, the relevant
Yukawa couplings should be of order [6]: $F_{ab} \sim \sqrt{m_{max} M_I} \sim 4 \times 10^{-8}$. One may further assume that two of the heavy Majorana neutrinos are degenerate in mass, say $N_{2,3}$ as before, which
enhances CP violation. In such a case, the scenario of [10], on Baryogenesis through coherent
oscillations of the two degenerate in mass right-handed fermions, may be realised. The Heavy
Majorana fermions $N_I$ thermalize only for $T < M_W$, so their decays at for $T > M_W$ are out of

Figure 1. Left: relevant graphs contributing to the BAU in the νMSM model with three
stere neutrinos. The lower two graphs are responsible for enhancement of CP violation if the
two heavy sterile neutrinos $N_{2,3}$ are degenerate in mass. Right: An example of heavy $N_1$ neutrino
abundance: thermal relic density $η_{N_1}$ vs $m_{N_1}/T$ in the scenario of [13] of resonant Leptogenesis.
equilibrium. One may worry in such a case that the induced BAU would depend on the initial conditions. However, inflation may set such the initial concentration of \( \mathcal{N}_I \) to practically zero value at the end of inflation. The relevant Majorana masses are small compared to the Sphaleron freeze-out Temperature, hence the total lepton number is conserved (the total Lepton number is zero but unevenly distributed between active and sterile neutrinos), this leads to “apparent” lepton number violation, so that the Lepton number of active left-handed \( \nu \) is transferred to Baryons due to equilibrated sphaleron processes. The coherent oscillations between the mass-degenerate singlet fermions have a frequency [10, 6]:

\[
\omega \sim \frac{|M_2^2 - M_3^2|/E_I \sim M_2 \Delta M/T},
\]

for \( \Delta M \equiv |M_2 - M_3| \ll M_3 \sim M_3, E_I \sim T \). For CP violation to occur (so that one can achieve the (observed) BAU) one must have that the oscillation rate is larger than the Hubble expansion rate of the Universe. Under the (important and rather delicate) assumption that the interactions with the plasma of SM particles in the early universe do not destroy quantum mechanical coherence of oscillations, one may have in this model baryogenesis occurring at 100 GeV, and a maximal baryon asymmetry \( \Delta = n_B - n_{\bar{B}}/(n_B + n_{\bar{B}}) \sim 1 \) when \( T_B \sim T_{\text{sph}} \sim T_{\text{eq}} \). Thus this mechanism for producing BAU seems quite effective, if in operation. For the case \( T_B \gg T_{\text{sph}} > T_{\text{eq}} \) the predicted \( n_B/s \) in this version of the \( \nu \text{MSM} \) model reads [6]:

\[
n_B/s \sim 1.7 \times 10^{-10} \delta_{CP} \left( \frac{10^{-5} M_\nu}{\Delta M/T} \right)^{2/3} \left( \frac{M_\nu}{10 \text{ GeV}} \right)^{5/3},
\]

with the CP violating factor expressed through the various mixing angles and CP-violating phases. This can be of \( O(1) \), according to the recent experimental data of neutrino oscillations. The observable value of the BAU, then, can be obtained for a wide range of parameters of the \( \nu \text{MSM} \) [6]. In particular, one may have Mass \( N_2 \) (\( N_3 \)) / (Mass \( N_1 \) = \( O(10^9) \)) , implying that the lightest sterile neutrino may have masses in the keV range, if \( M_{2,3} \) are of \( O(1-10) \) GeV. As we shall argue in the next section, this Lightest Sterile neutrino of this version of \( N = 3 \nu \text{MSM} \) is a natural Dark Matter (DM) candidate [6] [7].

Before closing this section we should mention that there are several theoretical scenarios that can explain the required mass hierarchy \( M_{2,3} \gg M_1 \) among the sterile neutrinos. These scenarios range from: (i) the imposition of flavour symmetries [6][16][17] (one starts with \( M_1 = 0 \) and \( M_2 \simeq M_3 > \text{GeV} \) if symmetry is unbroken, while Breaking of global Lepton symmetry give singlet fermion mass hierarchy, \( M_1 = O(\text{keV}) \ll M_{2,3} \)), to (ii) brane world scenarios [18] exploiting the associated exponential factor in a Randall-Sundrum-like framework [19] to obtain a large mass splitting (one sterile neutrino at the keV scale, while the other two could have masses of around \( 10^{11} \) GeV or heavier, and at the same time ensuring that the seesaw mechanism for active neutrinos works) from very moderately tuned parameters, and (iii) to Froggatt-Nielsen type mechanisms [20], whereby one fermion acquires mass via Higgs mechanism, while the rest via higher order multiple see-saw.

3. Neutrinos and the dark sector of the Universe

3.1 Sterile neutrinos in \( \nu \text{MSM} \) and DM

To be DM, the lightest massive sterile neutrino of the \( N = 3 \nu \text{MSM} \), \( N_1 \), must have a life time larger than that of the Universe. For this to happen, its coupling with SM matter must be superweak, \( \theta_1 G_F = \sum_{\alpha=e,\mu,\tau} v^2 |F_{\alpha\mu}|^2 M_\nu^2 \), with \( G_F \) denoting the Fermi coupling of the weak interactions. The width of \( N_1 \) for the decay \( N_1 \rightarrow \gamma \nu \) is expressed in terms of \( \theta_1 \) mixing angle as follows [6]:

\[
\Gamma_{N_1 \rightarrow \gamma \nu} = \frac{9aG_F^2}{16\pi^3} \sin^2(2\theta_1) M_1^5 \approx 5.5 \times 10^{-22} \theta_1^2 \left( \frac{M_1}{\text{keV}} \right)^5 \text{s}^{-1},
\]

which implies that, in order for the life time of \( N_1 \) to be larger than the Universe age, one must have \( \theta_1^2 \leq 1.8 \times 10^{-5} \left( \frac{M_1}{\text{keV}} \right)^5 \). The contributions to the mass matrix of the active neutrinos from this light sterile is estimated to be of order \( \delta m_{\nu} \sim \theta_1^2 M_1 \), which can be within the experimental error for the solar mass differences of active neutrinos if \( M_1 \geq 2 \) keV. The estimation of the production of the \( N_1 \) sterile neutrino in the Early universe is essential in order to have an idea of whether this candidate for DM satisfies the current astrophysical constraints [7][6]. Such an estimation requires taking into account the interactions of \( N_1 \) with the heavy degenerate
Figure 2. Astrophysical constraints for the $\nu$MSM model [7]. Left: Plot of the mixing angle $\theta_1$ of the lightest sterile neutrino (LSN) with SM matter vs its mass $M_1$. Middle: Plot of the mixing angle $\theta_2$ vs mass of the other sterile neutrinos (assumed degenerate). Right: Plot of the $\sin^2(2\theta_1)$ vs Mass $M_1$ of the LSN and the current BBN, x-ray and DM density ($\Omega_{N_1}$) constraints.

$N_{2,3}$ neutrinos. Because the decaying $N_1$ produces a narrow spectral line in the spectra of DM dominated astrophysical objects (e.g. galaxies), an important astrophysical constraint comes from the x-rays from such objects. The model is found consistent with all current astrophysical data, including x-ray constraints, Big Bang Nucleosynthesis (BBN) and Structure Formation data [7] (cf. fig. 2).

3.2 Neutrino condensates and dark energy in the Universe

Formation of fermion condensates dynamically in the Early Universe as in Nambu-Jona-Lasinio model, has been considered by several authors. In this spirit one may consider models of (effective) four-fermion interactions of sterile Majorana neutrino in the early Universe. The respective condensates may be formed, e.g. through a heavy scalar exchange. In the model of [21] it is argued that one light sterile neutrino (of mass of $O(10^{-3} \text{ eV})$) may form the condensate at a late era of the early universe, and be responsible for the observed acceleration (and dark energy component of the energy budget) of the Universe. The model is argued to be consistent with the solar neutrino data. Such ideas of neutrino forming condensates through self interactions and their relation to cosmology appear in other contexts, also related to baryogenesis, in a variety of works [22].

Figure 3. Left: The evolution of the mass of the neutrino vs $T$ and the redshift $z$. Middle: Neutrino Dark Energy evolution vs that of Dark Matter. Right: The relevant equation of state, for a potential $U(\varphi) = M^{\alpha+4}/\varphi^\alpha$, with $M = 2.39 \times 10^{-3} \text{ eV}$, $\alpha = 0.01$. From [24].

3.3. Dark energy from mass varying neutrinos

This attractive idea [23] can be formulated simply as follows: one couple scalar cosmic fields with potential $U(\varphi, T)$, where $T$ is the temperature of the Universe at a given era, and massless
fermions $\psi$ through Yukawa couplings $g\int_0^{\beta=kbT} dt \int a^3(t)d^3x \phi \bar{\psi} \psi$. The (T-dependent) fermion mass $m = g\varphi_c(T)$ is acquired through minimization w.r.t. to $\varphi$ (i.e. $\varphi = \varphi_c(T) = <\varphi>$ at the minimum) of the effective potential density $\Omega(\varphi) = U(\varphi) - \frac{1}{\beta a^3T} \log Z_D(\varphi)$, where $Z_D$ is the partition function at temperature $T$. The neutrino mass (which can be significantly higher at early stages of the Universe evolution) decreases with the temperature $T$ in an expanding Universe, and this has as a consequence the presence of a dark Energy fluid, whose equation of state resembles that of a cosmological constant at late eras [24] (cf. fig. 3). The models can be made consistent with current cosmologies for some choices of the potential $U(\varphi)$. However, a fundamental microscopic origin of such potentials is still lacking.

4. CPT Violation in the early Universe, active neutrinos and baryon asymmetry

So far we have assumed that the CPT symmetry holds in the Early Universe, and this produces matter and antimatter in equal amounts. An interesting idea is that during the Big Bang, one or more of the assumptions for the CPT theorem (Lorentz Invariance, unitarity and/or locality of interactions) breakdown (e.g. due to quantum gravity influences that may be strong at such early times), which results in CPT Violations (CPTV) and a naturally induced matter-antimatter asymmetry, without the need for extra sources of CP violation, such as sterile neutrinos. The simplest possibility [25] is through particle-antiparticle mass differences $m \neq \bar{m}$. These would affect the (anti) particle distributions $f(E, \mu) = [\exp(E - \mu)/T]^{-1}$, $E^2 = p^2 + m^2$ and similarly for antiparticle $m \to \bar{m}$, and thus generate a matter antimatter asymmetry in the relevant densities $n - \bar{n} = \int d^3p/[2\pi^3] \{f(E, \mu) - \{\bar{f}(E, \mu)\}]$. Assuming [25] quite reasonably that dominant contributions to Baryon asymmetry come from quarks-antiquarks, and that their masses are increasing, say, linearly with temperature $m \sim gT$, one estimates the induced baryon asymmetry by the fact that the maximum quark-antiquark mass difference is bounded by the current experimental bound on proton-antiproton mass difference, which is known to be less than $2 \cdot 10^{-9}$ GeV. This produces, unfortunately, too small BAU compared to the observed one. However, active neutrino-antineutrino mass differences alone may reproduce BAU; some phenomenological models in this direction have been considered in [26], considering for instance particle-antiparticle mass differences for active neutrinos compatible with current oscillation data. But particle-antiparticle mass difference may not be the only way by which CPT is violated. As discussed in [27], quantum gravity fluctuating effects that may be strong in the early universe, may act as an environment inducing decoherence for the (anti) neutrino, but with couplings between the particles and the environment that are different between the neutrino and antineutrino sectors. In [27] simple models of Lindblad decoherence were considered, with zero decoherence parameters in the particle sector, and non trivial only in the antiparticle sector, and such that there was a mixed energy dependence (some of the coefficients (with dimension of energy) were proportional to the antineutrino energies, $\gamma_i = (T/M_P) E$, while others were inversely proportional to them (and subdominant) $\gamma_j = 10^{-24} E^{1/2}$, $j \neq i$). The model is phenomenological and its choice was originally motivated by fitting the LSND “anomalous data” in the antineutrino sector with the rest of the neutrino data. In this way one can derive an active (light) $\nu - \bar{\nu}$ asymmetry of order $A = (n_{\nu} - n_{\bar{\nu}})/(n_{\nu} + n_{\bar{\nu}}) = \tilde{\gamma}_i = T/M_P \cdot \frac{E}{\sqrt{2 m^2}}$. This Lepton number violation is communicated to the Baryon sector by means of B+L violating sphaleron processes, as usual, and one can thus reproduce the observed BAU without the need for extra sources of CP violation and thus sterile neutrinos. Unfortunately, at present such models lack microscopic understanding, but we think they are worth pursuing. For other scenarios of neutrino-antineutrino CPT violation induced by local curvature effects in geometries of the early universe, and its connection to baryogenesis, see [28].
