

Search for Coherent Muon-to-Electron Transition (COMET) at a sensitivity better than 10^{-16}

Richard D'Arcy

On behalf of the COMET collaboration

NuFact '11 – 01/08/11

Motivation – Lepton Flavour Violation

- Lepton flavour conservation is a fundamental property of the Standard Model (SM).
- LFV of neutrinos has been confirmed.
- LFV of charged leptons is unobserved.
- The SM predicts a branching ratio for LFV processes of $O(10^{-50})$. An example of such a process is:

$$B(\mu \rightarrow e\gamma) = \frac{3\alpha}{32\pi} \left| \sum_{i=2,3} U_{\mu i}^* U_{ei} \frac{\Delta m_{1i}^2}{M_W^2} \right|^2 < 10^{-54}$$

- New Physics models (SUSY, GUTs, etc.) increase this BR dramatically to $\approx 10^{-15}$.
- LFV experiments may therefore provide a complimentary probe to beyond SM physics at the LHC, having reach beyond the TeV scale.

Motivation – Charged Lepton Flavour Violation

process	present limit	near future	comments
$\mu \rightarrow e\gamma$	1.2×10^{-11}	10^{-13}	MEG at PSI
$\mu \rightarrow eee$	1.0×10^{-12}	$10^{-14} - 10^{-15}$	PSI and MUSIC ?
$\mu N \rightarrow eN$ (in Ti)	7×10^{-13}	10^{-18}	PRISM
$\mu N \rightarrow eN$ (in Al)	none	10^{-16}	COMET and Mu2e
$\tau \rightarrow e\gamma$	1.1×10^{-7}	$10^{-8} - 10^{-9}$	super B factory
$\tau \rightarrow eee$	2.7×10^{-7}	$10^{-8} - 10^{-9}$	super B factory
$\tau \rightarrow \mu\gamma$	6.8×10^{-8}	$10^{-8} - 10^{-9}$	super B factory
$\tau \rightarrow \mu\mu\mu$	2×10^{-7}	$10^{-8} - 10^{-9}$	super B factory

○ $\mu \rightarrow e\gamma$ and $\mu \rightarrow eee$ processes suffer heavily from accidental backgrounds of daughter particles and are thus limited to $O(10^{-13})$.

○ Therefore conversion experiments, utilising the process

$$\mu^- + N(A, Z) \rightarrow e^- + N(A, Z)$$

are required as they search for single, monoenergetic signal electrons.

○ The large number of muons available ($\approx 10^{18}$ μ/yr) results in a ‘high’ sensitivity to LFV.

← Different SUSY and non-SUSY new physics models.

← All three stars for muon-to-electron conversion in an atom.

Table 8: “DNA” of flavour physics effects for the most interesting observables in a selection of SUSY and non-SUSY models ★★★★★ signals large effects, ★★ visible but small effects and ★ implies that the given model does not predict sizable effects in that observable.

What is muon-to-electron conversion?

Muon decay in orbit (DIO)

$$\mu^- \rightarrow e^- \bar{\nu}_e \nu_\mu$$

Muon coherent capture (MC)

$$\mu^- + (A, Z) \rightarrow \nu_\mu + (A, Z - 1)$$

Standard Model Processes

Muon-to-electron conversion

$$\mu^- + (A, Z) \rightarrow e^- + (A, Z)$$

Beyond Standard Model Process

Other backgrounds:

- Prompt background
- Muon decay in flight (DIF)
- Beam electrons

Signal:

A single mono-energetic electron with energy

$$E_e = m_\mu - B_\mu(A1) \simeq 105 \text{ MeV}$$

Current status of cLFV

SINDRUM-II at PSI (target – Au)

Muon beam intensity $\sim 10^{7-8}/\text{sec}$

Upper limit of 7×10^{-13}

✓ published result 2004

MEG at PSI ($\mu^+ \rightarrow e^+ \gamma$)

Upper limit of 2.4×10^{-12}

✓ published result 2011

COMET at J-PARC (target – Al)

Muon beam intensity $\sim 10^{11}/\text{sec}$

Proposed sensitivity of $< 10^{-16}$

(SINDRUM results published in 2004)

Improvements (background rejection)

The COMET (J-PARC - E21) Experiment

○ **CO**herent **MU**on-to-**E**lectron Transition experiment.

○ COMET / PRISM is a two stage experiment with a proposed sensitivity to cLFV of 10^6 times better than current limits.

○ Unique curved solenoidal beamline design for momentum selection.

○ Pion capture and muon transport by novel superconducting solenoid system.

Mu2e at Fermilab

- Similar sensitivity to COMET with similar ideas (curved solenoids yet with slightly different geometry).
- Built on the ideas and groundwork of the MECO experiment.
- Collaborations between COMET and Mu2e are prosperous (e.g. radiation damage to superconductors R&D)

Design Differences between Mu2e and COMET

	<u>Mu2e</u>	<u>COMET</u>
Proton beam	Fermilab (pulsed)	J-PARC (pulsed)
Muon beamline	S-shape	C-shape
Electron Spectrometer	Straight solenoid	Curved solenoid

Proton Beam (pulsed)

- A pulsed proton beam is needed to reject beam-related prompt background.
- Requirements:
 - pulse separation $> 1 \mu\text{sec}$ (muon lifetime in Al is 880ns)
 - pulse width $< 100 \text{ nsec}$
- Beam parameters:
 - beam power – 56 kW
 - beam energy – 8 GeV
 - avg. current – $7 \mu\text{A}$

- Beam extinction:

$$R_{\text{Ext}} = \frac{\text{number of protons between pulse}}{\text{number of protons in a pulse}} < 10^{-9}$$

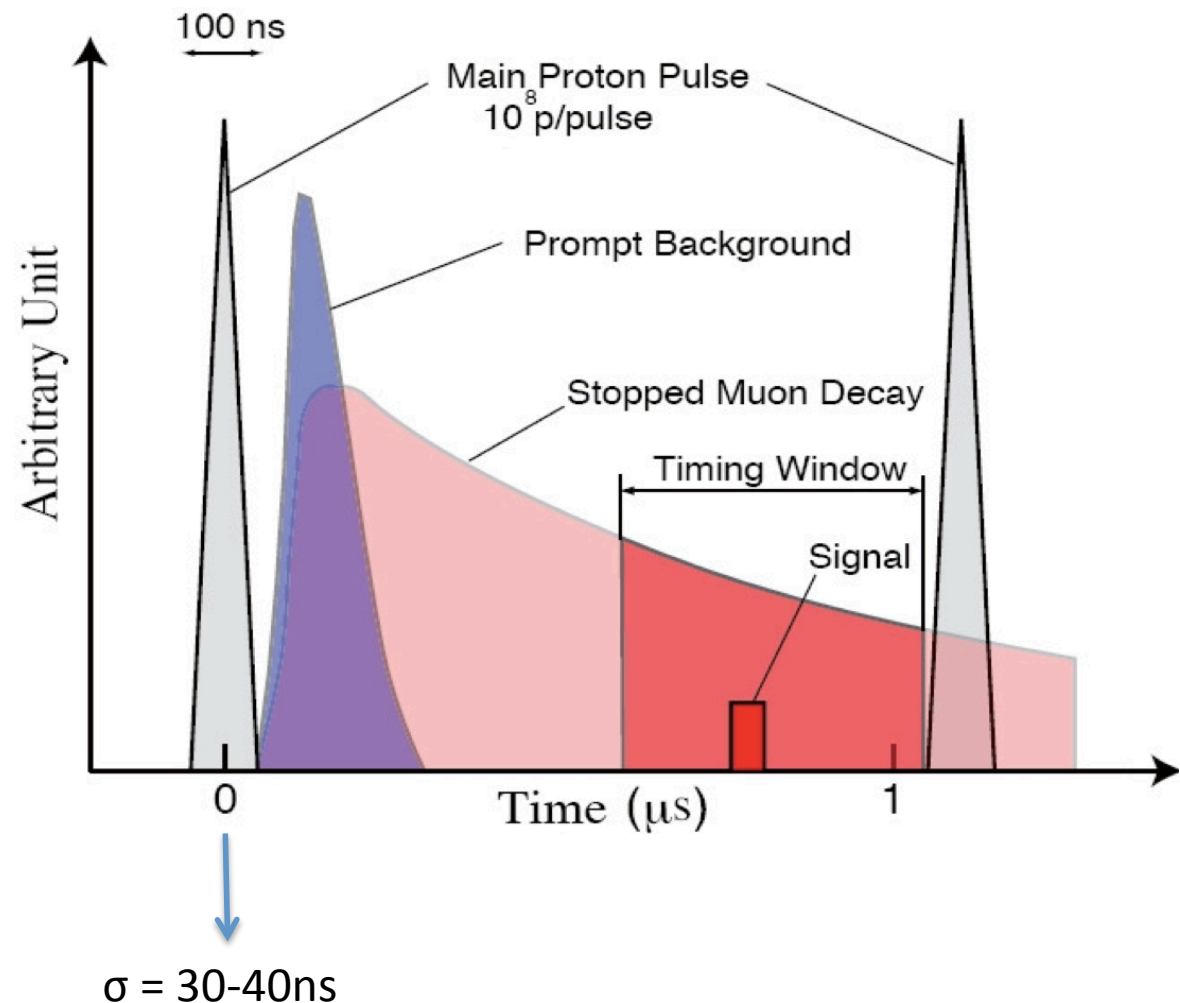

Proton Beam (extinction)

○ Muonic lifetime is dependent on target material (Z number). For Al the lifetime is 880ns.

○ Bunch structure:

- separation – $1.3 \mu\text{s}$
- length – 100 ns
- protons/bunch – 1.2×10^8
- extinction – 10^{-9}

○ Without extinction we would encounter problems with prompt background from proton interactions. This problem is reduced with bunching.

Proton Beam (extinction measurement)

Bunched slow extraction:

- Measurements taken from the J-PARC secondary beamline – K1.1BR
- Extinction:
 $(5.4 \pm 0.6) \times 10^{-7}$

Proton Beam (extinction measurements)

Abort beamline
measurements

Secondary
beamline
measurements

Consistent with $O(10^{-7})$ in the J-PARC
MR

Double injection
kicking

× additional factor of $O(10^{-6})$

External extinction
device

× additional factor of $O(10^{-3})$

The COMET collaboration is confident of achieving
proton extinction of $< O(10^{-9})$

Curved solenoids

- In a curved solenoid the centre of the helical trajectory of a charged particle drifts towards the perpendicular direction to the curved solenoid plane.

$$D = \frac{p}{qB} \theta_{bend} \frac{1}{2} \left(\cos \theta + \frac{1}{\cos \theta} \right)$$

D : drift distance

B : Solenoid field

θ_{bend} : Bending angle of the solenoid channel

p : Momentum of the particle

q : Charge of the particle

θ : $\text{atan}(P_T/P_L)$

- A compensating magnetic field is introduced, according to:

$$B_{comp} = \frac{p}{qr} \frac{1}{2} \left(\cos \theta + \frac{1}{\cos \theta} \right)$$

p : Momentum of the particle

q : Charge of the particle

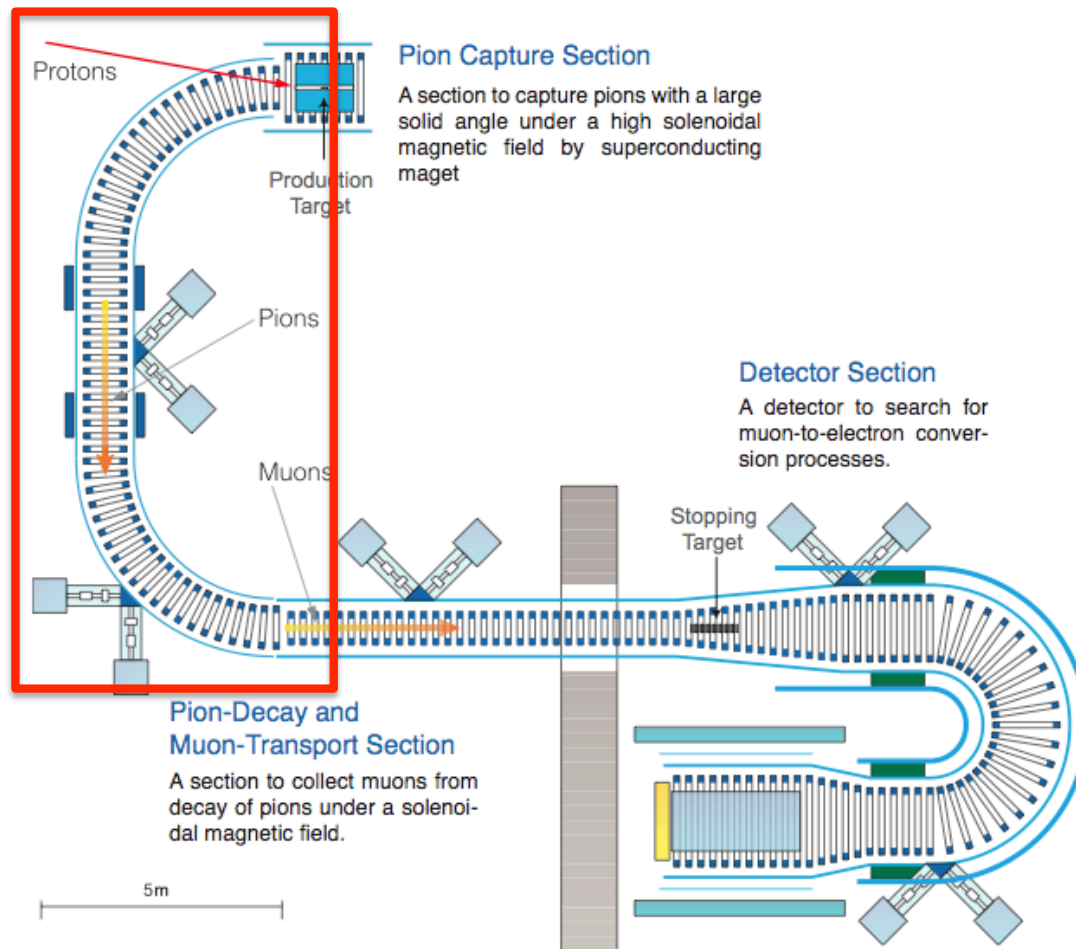

r : Major radius of the solenoid

θ : $\text{atan}(P_T/P_L)$

This can be used for charge and momentum selection.

Curved solenoids (muon transport)

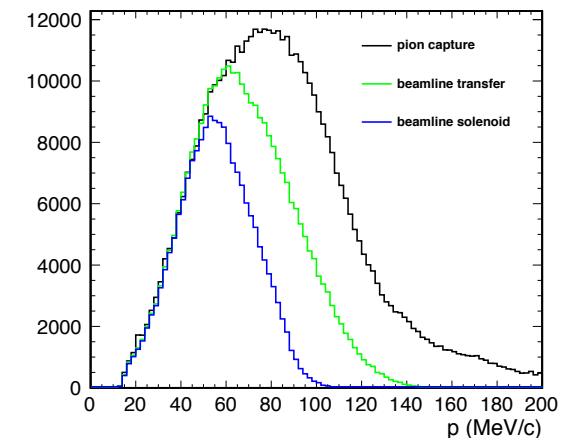

○ Muon transport consists of two 90° bent solenoids:

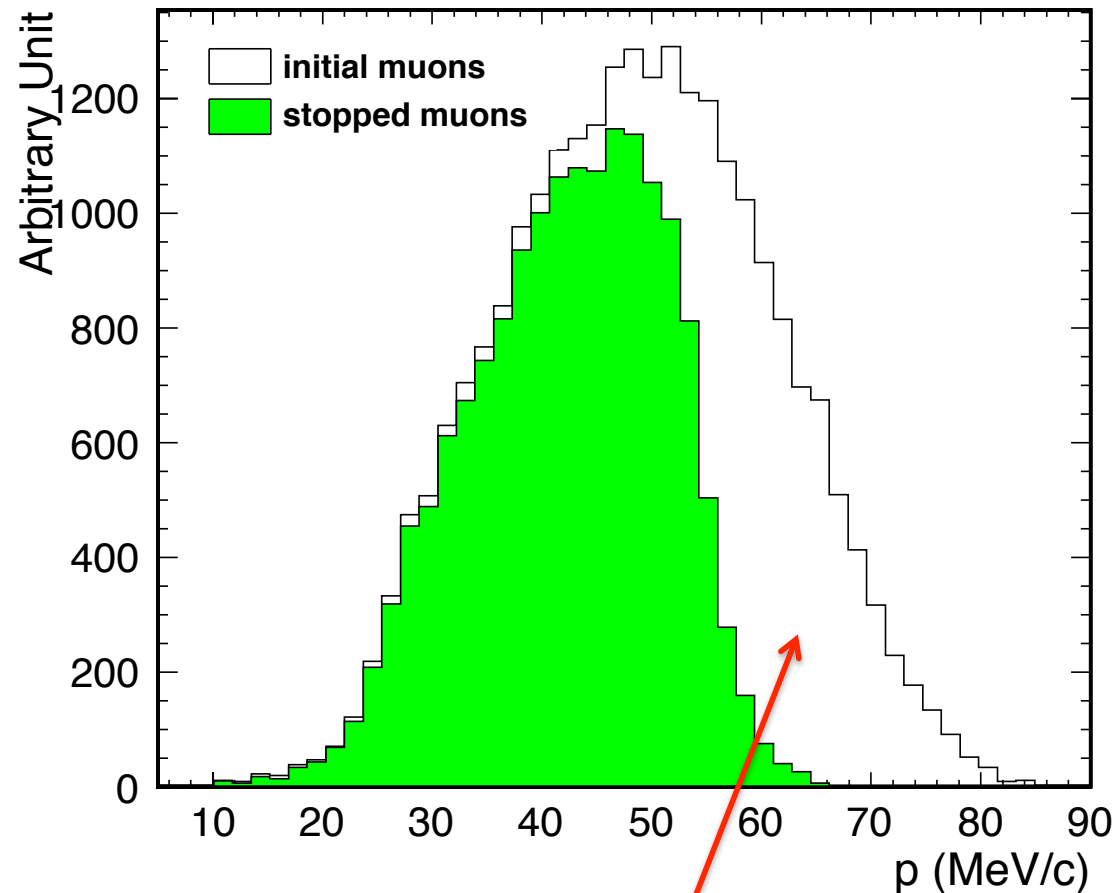

- magnetic field – 3 T
- total bend – 180°
- radius of curvature – 3 m

○ Designed to eliminate muons with high momentum.

○ Momentum selection proportional to bending angle.

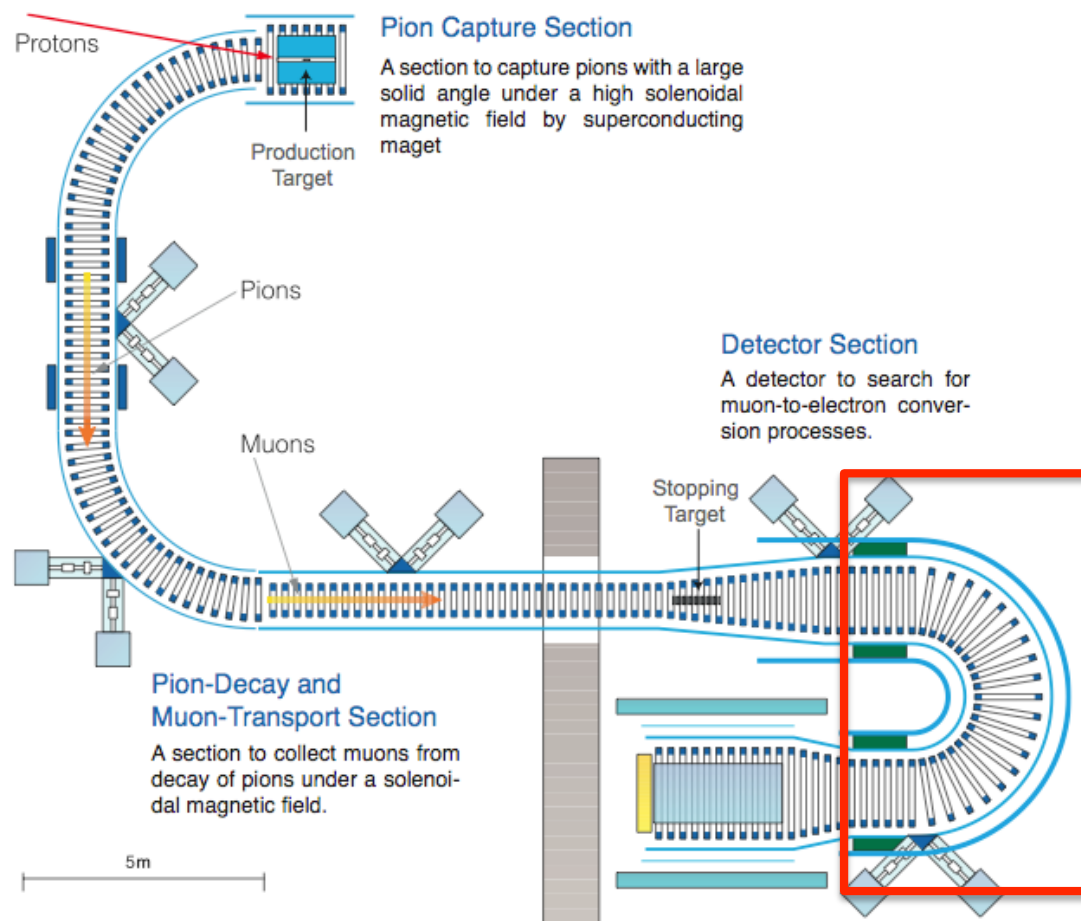

Curved solenoids (muon transport)

No high energy muons after 180° bend selection

- COMET simulation method:
 - protons incident on a graphite target (MARS)
 - subsequent particle distribution tracked through a model of the experiment (Geant4)

Curved solenoids (electron transport)

- Electron transport consists of one 180° bent solenoid:
 - magnetic field – 1 T
 - total bend – 180°
 - radius of curvature – 2 m
- Designed to eliminate:
 - positively charged particles (e.g. protons from muon capture)
 - negatively charged particles $p < 60 \text{ MeV/c}$
- And select signal electrons of $p > 60 \text{ MeV/c}$.
- Detector rates are drastically reduced as a result of this.

Curved solenoids (electron transport efficiency)

- The plot of transmission efficiency is produced with the DIO blockers placed 20cm below the beamline axis.
- The collimators and blockers require optimisation to achieve a detector rate of 1-10 kHz within the timing window.

- Prompt background is small due to extinction, therefore other backgrounds dominate (DIO, DIF, etc.).
- The electron spectrometer provides huge suppression of DIO electrons (augmented by a series of DIO blockers).

Sensitivity and Background

Sensitivity:

Single event sensitivity = $(N_p \cdot N_{\mu/p}^{stop} \cdot f_{cap} \cdot A_{\mu-e})^{-1}$	2.6×10^{-17}
90% confidence level upper limit	6.0×10^{-17}
Events per 1×10^{-16} BR	3.8

Background:

Radiative Pion Capture	0.05
Beam Electrons	$< 0.1^\ddagger$
Muon Decay in Flight	< 0.0002
Pion Decay in Flight	< 0.0001
Neutron Induced	0.024
Delayed-Pion Radiative Capture	0.002
Anti-proton Induced	0.007
Muon Decay in Orbit	0.15
Radiative Muon Capture	< 0.001
μ^- Capt. w/ n Emission	< 0.001
μ^- Capt. w/ Charged Part. Emission	< 0.001
Cosmic Ray Muons	0.002
Electrons from Cosmic Ray Muons	0.002
Total	0.34

Status

- Proton extinction in the secondary beamline at J-PARC has been measured.
- Design of superconducting solenoid cavities has been realised.
- A prototype of the first ever superconducting pion capture solenoid has been built at Osaka University. Experiments (MuSIC, etc.) are currently in progress, utilising this and the first 36° of muon transport solenoids.
- Conceptual design report (CDR) submitted, receiving Stage-1 approval as E21 at J-PARC PAC, 2009 - vindication of physics motivation and feasibility.
- Stage-2 approval will be assessed in the coming months following submission of a technical design report (TDR) to J-PARC PAC.

Summary

- Physics motivation for cLFV is robust, allowing a probe of beyond-LHC energy scales.
- Muon-to-electron conversion provides the current best chance of observing cLFV with $> 10^{18} \mu/\text{yr}$.
- COMET/conversion experiments can achieve sensitivity beyond 10^{-13} because:
 - Pulsed proton beam for background rejection
 - Curved solenoid magnets for momentum rejection and signal selection
- New collaborators are welcome!
