Abstract. The MiniBooNE neutrino oscillation search experiment at Fermilab has recently updated results from a search for $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations, using a data sample corresponding to 8.58×10^{20} protons on target in anti-neutrino mode. These high statistics results represent an increase in statistics of 52% compared to the results published in 2010. An excess of 57.7 ± 28.5 events is observed in the energy range 200 MeV $< E_\nu <$ 3000 MeV. The data favor LSND-like $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations over a background only hypothesis at 91.1% confidence level in the energy range $475 < E_\nu <$ 3000 MeV.

1. Introduction

Motivated by the LSND observation of an excess of observed $\bar{\nu}_e$ events above background prediction in a $\bar{\nu}_\mu$ beam [1], the MiniBooNE experiment was designed to test the neutrino oscillation interpretation of the LSND signal in both neutrino and anti-neutrino modes. The MiniBooNE collaboration has performed a search for $\nu_\mu \to \nu_e$ oscillations with 6.486×10^{20} protons on target (POT), the results of which showed no evidence of an excess of ν_e events for neutrino energies above 475 MeV [2]. Despite having observed no evidence for oscillations above 475 MeV, the MiniBooNE $\nu_\mu \to \nu_e$ search observed an excess of 128.8 ± 43.4 events at low energy, between 200-475 MeV [3]. Although the excess is incompatible with LSND-type oscillations within the simple two neutrino oscillation framework, several hypotheses, including sterile neutrino oscillations with CP violation, anomaly-mediated neutrino-photon coupling, and many others, have been proposed that provide a possible explanation for the excess itself [4]. In some cases, these theories offer the possibility of reconciling the MiniBooNE ν_e excess with the LSND $\bar{\nu}_e$ excess. A search in antineutrino mode provides a more direct test of the LSND signal, which was observed with antineutrinos. The MiniBooNE collaboration has published a search for $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations with 5.66×10^{20} POT, the results of which showed an evidence of an excess of $\bar{\nu}_e$ events for neutrino energies above 475 MeV [6]. The allowed regions from the fit, shown in Fig. 1, are consistent with $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations in the 0.1 to 1 eV^2 Δm^2 range and consistent with the allowed region reported by the LSND experiment [1]. The data show an excess of 43.2 ± 22.5 events: 277 electron-like events have been observed in $200 < E_\nu < 3000$ MeV reconstructed energy range, compared to an expectation of $233.8 \pm 15.3(stat) \pm 16.5(syst)$ events [6]. In the energy range $475 < E_\nu < 1250$ MeV, the observed $\bar{\nu}_e$ events, when constrained by the $\bar{\nu}_\mu$ data events, have a $\chi^2/DF = 18.5/6$ and a probability of 0.5% for a background-only hypothesis.
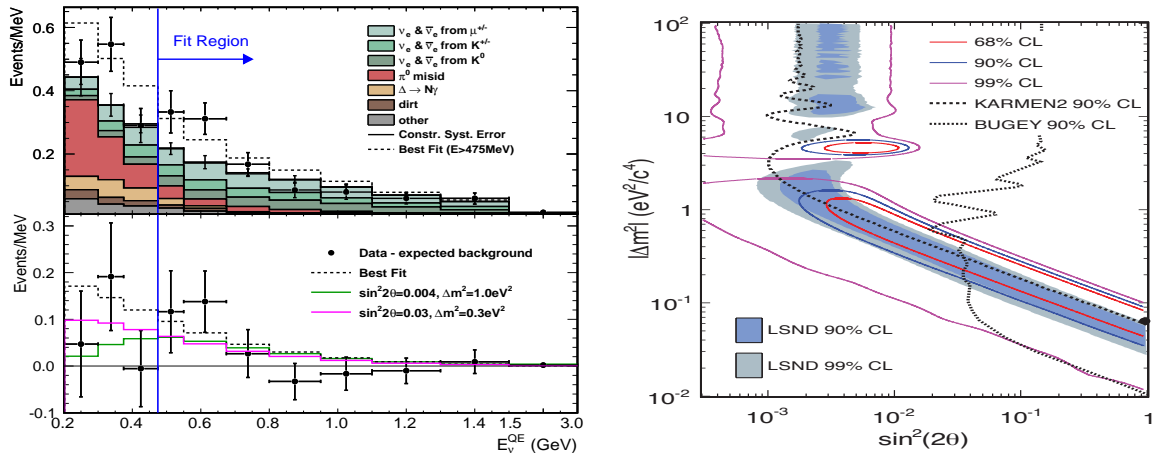

Figure 1. Results obtained with 5.66×10^{20} POT exposure. *Top Left*: Reconstructed E_ν distribution of $\bar{\nu}_e$ CCQE candidates in MiniBooNE anti-neutrino running. *Bottom Left*: The difference between the data and predicted backgrounds as a function of reconstructed neutrino energy. The error bars include both statistical and systematic components. Also shown in the figure are expectations from the best oscillation fit with $E_\nu > 475$ MeV, $(\Delta m^2, \sin^2 2\theta) = (0.064$ eV^2, 0.96) where the fit is extrapolated below 475 MeV and from other neutrino oscillation parameter sets in the LSND allowed region. *Right*: MiniBooNE 68%, 90%, and 99% C.L. allowed regions for events with $E_\nu > 475$ MeV within a two neutrino $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillation model, obtained with 5.66×10^{20} POT exposure [6]. The shaded areas show the 90% and 99% C.L. LSND allowed regions. The black dot shows the best fit point.

2. New $\bar{\nu}_\mu \to \bar{\nu}_e$ results

In this report we describe the latest unpublished results that the MiniBooNE collaboration updated in the search for $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations, using a data sample corresponding to 8.58×10^{20} POT exposure. The analysis technique used here was already described [3, 5, 6] and assumes only $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations with no $\bar{\nu}_\mu$ disappearance and no ν_μ oscillations. The signature of $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations is an excess of $\bar{\nu}_e$-induced charged-current quasi-elastic (CCQE) events. Fig. 2 (top left) shows the reconstructed E_ν distribution of observed $\bar{\nu}_e$ CCQE candidates and background expectation. The data show an excess of 57.7 ± 28.5 events: 412 electron-like events have been

Table 1. The number of data, fitted background, and excess events in the $\bar{\nu}_e$ appearance analysis for different E_ν ranges. The uncertainties include both statistical and constrained systematic errors. All known systematic errors are included in the systematic error estimate.

E_ν range [MeV]	Data	Background	Event Excess
200 - 475	189	$150.4 \pm 12.3 \pm 13.9$	38.6 ± 18.5
475 - 675	80	$58.3 \pm 7.6 \pm 5.5$	21.7 ± 9.4
475 - 1250	168	$151.7 \pm 12.3 \pm 15.0$	16.3 ± 19.4
475 - 3000	223	$203.9 \pm 14.3 \pm 20.2$	19.1 ± 24.7
200 - 3000	412	$354.3 \pm 18.8 \pm 21.4$	57.7 ± 28.5

observed in $200 < E_\nu < 3000$ MeV reconstructed energy range, compared to an expectation of $354.3 \pm 18.8(stat) \pm 21.4(syst)$ events (see also Table 1). Fig. 2 (bottom left) shows the event excess as a function of E_ν. Using a likelihood-ratio technique, the best MiniBooNE oscillation
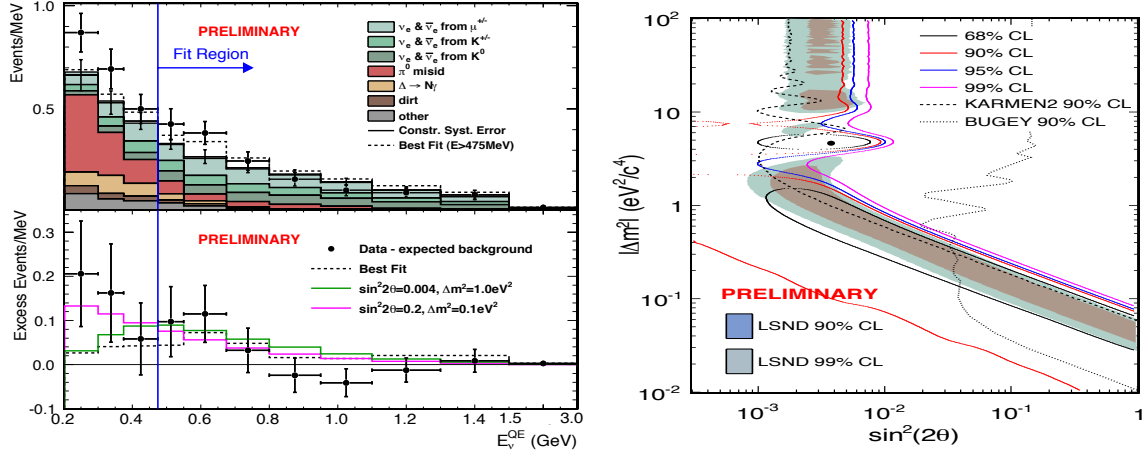

Figure 2. *Top Left*: Reconstructed E_ν distribution of $\bar\nu_e$ CCQE candidates in MiniBooNE antineutrino running. *Bottom Left*: The difference between the data and predicted backgrounds as a function of reconstructed neutrino energy. The error bars include both statistical and systematic components. Also shown in the figure are expectations from the best oscillation fit with $E_\nu > 475$ MeV, $(\Delta m^2, \sin^2 2\theta) = (4.64$ eV^2, 0.00337$)$ where the fit is extrapolated below 475 MeV and from other neutrino oscillation parameter sets in the LSND allowed region. *Right*: MiniBooNE 68%, 90%, and 99% C.L. allowed regions for events with $E_\nu > 475$ MeV within a two neutrino $\bar\nu_\mu \to \bar\nu_e$ oscillation model. The black dot shows the best fit point.

fit for $475 < E_\nu < 3000$ MeV occurs at $(\Delta m^2, \sin^2 2\theta) = (4.64$ eV^2, 0.00337$)$. The energy range $E_\nu > 475$ MeV has been chosen for the fit as this is the energy range MiniBooNE used for searching for oscillations in neutrino mode. Also, this energy range avoids the region of the unexplained low-energy excess in neutrino mode [3]. The χ^2 for the best-fit point in the energy range of $475 < E_\nu < 1250$ MeV is 4.3 for 4 DF, corresponding to a χ^2-probability of 36%. The probability of the background-only fit relative to the best oscillation fit is 8.9%. Fig. 2 (right) shows the MiniBooNE 68%, 90%, and 99% C.L. closed contours for $\bar\nu_\mu \to \bar\nu_e$ oscillations in the $475 < E_\nu < 3000$ MeV energy range. Both the old and updated results are consistent with the LSND oscillation region although the updated result has a much reduced significance for LSND-like oscillation signal. The updated results shown an excess of 38.6 ± 18.5 events in the low energy region $200 < E_\nu < 475$ MeV, more prominent than in the previous result. Part of this excess may be attributed to the neutrino-mode low energy excess [3], given 22% neutrino contribution to the beam in antineutrino-mode. With the oscillation fit region extended down to 200 MeV, the MiniBooNE closed contours for $\bar\nu_\mu \to \bar\nu_e$ oscillations are similar as shown in Fig 3 (left). Fig 3 (right) shows the fit with the subtraction of 17 events expected assuming the low energy excess scales with neutrino component of the beam. The best oscillation fit point without and with this subtraction correspond to $(\Delta m^2, \sin^2 2\theta) = (4.64$ eV^2, 0.0045$)$ and $(\Delta m^2, \sin^2 2\theta) = (4.64$ eV^2, 0.0037$)$, respectively.

3. Conclusion and next steps

The MiniBooNE experiment observes an excess of 57.7 ± 28.5 events in the full energy range 200 MeV $< E_\nu < 3000$ MeV for a data sample corresponding to 8.58×10^{20} POT. The allowed regions from the fit, shown in Fig. 2, are consistent with $\bar\nu_\mu \to \bar\nu_e$ oscillations in the 0.1 to 1 eV^2 Δm^2 range. The data favor LSND-like oscillations over a background only hypothesis at 91.1% confidence level. With new data update excess is indicated at low energy, as with neutrinos. The MiniBooNE antineutrino results are statistically limited and a larger data sample will be needed
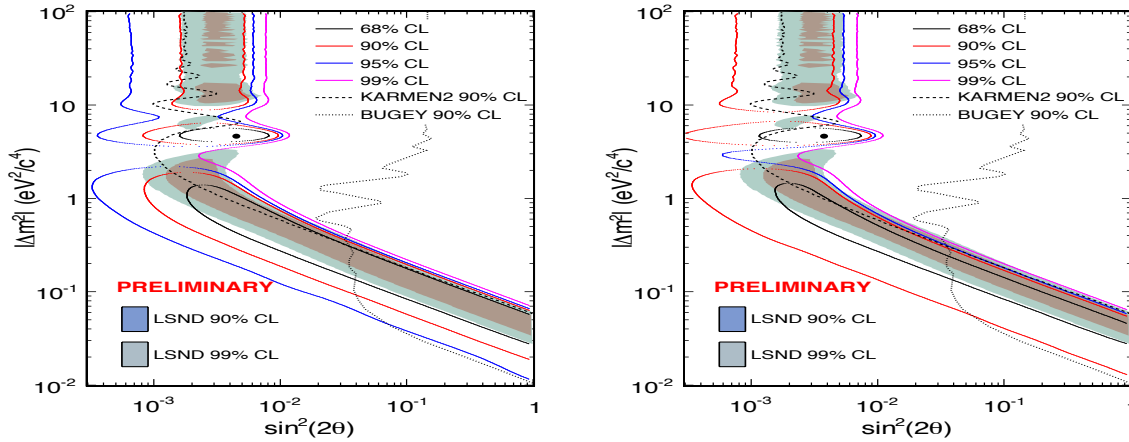

Figure 3. *Left*: MiniBooNE 90% and 99% C.L. allowed regions for events with $E_\nu > 200$ MeV within a two neutrino $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillation model. The shaded areas show the 90% and 99% C.L. LSND allowed regions. *Right*: MiniBooNE 90% and 99% C.L. allowed regions for events with $E_\nu > 200$ MeV within a two neutrino $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillation model, with the subtraction of the expected 17 event excess in the $200 < E_\nu < 475$ MeV low-energy region from the neutrino component of the beam.

to make more definitive statements. MiniBooNE's requested additional running to reach close to 15×10^{20} POT and significantly increase the current data statistics before anticipated accelerator shutdown at Fermilab expected in Spring 2012. In the next step a combined $\bar{\nu}_\mu \to \bar{\nu}_e$ and $\nu_\mu \to \nu_e$ analysis will be performed. In addition, several proposed short-baseline experiments [7] will be sensitive to $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations in the 0.1 to 1 eV^2 Δm^2 range.
